MEDICINE TO MITHRIDATES.

THE

LONDON ENCYCLOPÆDIA,

OR

UNIVERSAL DICTIONARY

OF

SCIENCE, ART, LITERATURE, AND PRACTICAL MECHANICS,

COMPRISING A

POPULAR VIEW OF THE PRESENT STATE OF KNOWLEDGE.

ILLUSTRATED BY

NUMEROUS ENGRAVINGS, A GENERAL ATLAS,

AND APPROPRIATE DIAGRAMS.

Sic oportet ad librum, presertim miscellanei generis, legendum accedere lectorem, ut solet ad convivium conviva civilis. Convivator annititur omnibus satisfacere; et tamen si quid apponitur, quod hujus aut illius palato non respondeat, et hic et ille urbane dissimulant, et alia fercula probant, ne quid contristent convivatorem. *Erasmus.*

A reader should sit down to a book, especially of the miscellaneous kind, as a well-behaved visitor does to a banquet. The master of the feast exerts himself to satisfy his guests; but if, after all his care and pains, something should appear on the table that does not suit this or that person's taste, they politely pass it over without notice, and commend other dishes, that they may not distress a kind host. *Translation.*

BY THE ORIGINAL EDITOR OF THE ENCYCLOPÆDIA METROPOLITANA,

ASSISTED BY EMINENT PROFESSIONAL AND OTHER GENTLEMEN.

IN TWENTY-TWO VOLUMES.

VOL. XIV.

MEDICINE.

MED'ICAL, *adj.*
MED'ICALLY, *adv.*
MEDIC'AMENT, *n. s.*
MEDICAMEN'TAL, *adj.*
MEDICAMEN'TALLY, *adv.*
MED'ICATE, *v. a.*
MEDICA'TION, *n. s.*
MEDIC'INABLE, *adj.*
MEDIC'INAL,
MEDIC'INALLY, *adv.*
MED'ICINE, *n. s.* & *v. a.*

Lat. *medicus, medicina*; Fr. *medecine*. Physical, or relating to the healing art. Medicament is any thing used in that art; a topical application. To medicate, to tincture or impregnate with medicine or any thing of a medicinal nature. Medicinable and medicinal, having the power of healing, or of physic; appertaining to physic. Medicine is physic; any remedy prescribed by the faculty: the verb is obsolete, but used by Shakspeare as signifying to operate upon as physic.

A merry heart doeth good like a *medicine*; but a broken spirit drieth the bones. *Prov.* xvii. 22.

O, my dear father! restauration, hang
Thy *medicine* on my lips; and let this kiss
Repair those violent harms.
Shakspeare. King Lear.

Not all the drowsy syrups of the world
Shall ever *medicine* thee to that sweet sleep
Which thou owedst yesterday. *Shakspeare.*

Come with swords as *medicinal* as true,
Honest as either; to purge him of that humour
That presses him from sleep. *Id. Winter's Tale.*

Every *medicine* is an innovation, and he that will not apply new remedies must expect new evils; for time is the greatest innovator; and if time of course alter things to the worse, and wisdom and counsel shall not alter them to the better, what shall be the end? *Lord Bacon.*

The watering of the plant with an infusion of the *medicine* may have more force than the rest, because the *medication* is oft renewed. *Id.*

Accept a bottle made of a serpentine stone, which gives any wine infused therein for four and twenty hours the taste and operation of the spa water, and is very *medicinable* for the cure of the spleen. *Wotton.*

Admonitions, fraternal or paternal, then public reprehensions; and, upon the unsuccessfulness of these milder *medicaments*, the use of stronger physick, the censures. *Hammond.*

Thoughts my tormentors, armed with deadly stings,
Mangle my apprehensive tenderest parts;
Exasperate, exulcerate, and raise
Dire inflammation, which no cooling herb
Nor *medicinal* liquor can assuage. *Milton.*

The fumes, steams, and stenches of London, do so *medicate* and impregnate the air about it, that it becomes capable of little more. *Graunt.*

Innumerable persons blind, deaf, dumb, lame, and maimed, he restored to the use of their faculties, and members respectively, without any *medicinal* applications, or any natural means conducible to those purposes. *Barrow.*

Learned he was in *medicinal* lore,
For by his side a pouch he wore,
Replete with strange hermetick powder
That wounds nine miles point-blank with solder.
Butler.

In this work attempts will exceed performances, it being composed by snatches of time, as *medical* vacation would permit. *Browne's Vulgar Errours.*

That which promoted this consideration, and *medically* advanced the same, was the doctrine of Hippocrates. *Id.*

He advises to observe the equinoxes and solstices, and to decline *medication* ten days before and after. *Id.*

The substance of gold is invincible by the powerfullest action of natural heat; and that not only alimentally in a substantial mutation, but also *medicamentally* in any corporeal conversion. *Id.*

The hearts and galls of pikes are *medicinable*. *Walton.*

A cruel wound was cured by scalding *medicaments*, after it was putrified; and the violent swelling and bruise of another was taken away by scalding it with milk. *Temple's Miscellany.*

I wish to die, yet dare not death endure;
Detest the *medicine*, yet desire the cure. *Dryden.*

The second causes took the swift command
The *medicinal* head, the ready hand;
All but eternal doom was conquered by their art.
Id.

Such are called *medicinal*-days by some writers wherein no crisis or change is expected, so as to forbid the use of medicines; but it is most properly used for those days wherein purging, or any other evacuation, is more conveniently complied with. *Quincy.*

To this may be ascribed the great effects of *medicated* waters. *Arbuthnot.*

No present health can health ensure
For yet an hour to come;
No *medicine*, though it oft can cure,
Can always balk the tomb. *Cowper.*

1. MEDICINE, from Lat. medico, to heal, in its verbal signification, means, as we have seen, the art of curing, mitigating, and preventing disease; as a substantive it signifies the material employed to effect these purposes.

2. In treating of this subject, as a science and an art, we shall first present our readers with an historical account of the successive revolutions which medicine has undergone from the earliest periods; we shall then give a short estimate of its present condition; engage in the consideration of classifying or arranging disease; and finally treat of ailments as they occur in practice, enquiring into their sources remote and immediate, and the methods best adapted to remedy and remove them.

PART I.

HISTORY OF MEDICINE.

3. To reason from the general course of nature, says an author of whose labors we shall avail ourselves in the present article, it is evident that man, subjected as he is to the influence of a variety of causes which may disorder the action of his organs, must very soon have been obliged to seek for the means of alleviating the pains and of curing the diseases with which he was affected. As he cannot seclude himself entirely from the constant agency of many of those external causes; and as he carries within him several others which are destined to act at particular periods of life, or which may at any time exert their influence; we may with safety affirm that the first trials of particular remedies bear almost as ancient a date as the existence of man himself. Among the most rude and uncultivated tribes, as those of New Holland, and New Zealand, of Lapland, and Greenland, of North America and the interior of Africa, we find traces of the practice of medicine and surgery. The savages in these countries know how to distinguish different diseases, and to apply a more or less suitable method of treatment; and they are acquainted with the use of several remedies which form no part of their daily food. These uncivilised communities present to us the picture of mankind in their infancy, and give us a lively idea of the original state of all nations.

4. From their first existence, men must have had diseases which they naturally sought to cure or alleviate. To attain these objects they tried a variety of methods. But we may presume that their discoveries were in general very slow, and more frequently the offspring of fortunate accidents than the result of rational investigation. Men receiving by tradition a knowledge of the discoveries which had been already made, would soon find themselves obliged to make new observations for themselves, and in this manner their acquisitions would gradually increase. In these early ages all the knowledge of the tribe formed a common stock; and their imperfect arts might be exercised by all those who were endowed with a certain portion of intelligence. Medicine therefore existed before there were any regular physicians. (Cabanis).

5. Whether instinct or actual observation had most to do with the origin of medicinal attempts has been the subject of dispute, but it is most probable that each had a share in the matter; and, although we must receive as fabulous and unworthy of full credence several accounts which have been transmitted to us on the subject of men being taught the virtues of herbs by witnessing the instinct of brutes, it is more than probable that some of these narrations have their foundation in truth.

6. The necessity of medicine from the earliest periods being admitted, says Le Clerc, it may naturally enough be inferred, that both reason and chance might place several remedies in the hands of man; and the most ancient accounts we find extant, respecting the manner in which medicinal virtues were ascertained to exist in certain plants, attribute the discovery of such virtues to accidental observation. We learn from fabulous history that Glaucus, son of Minos king of Crete, having fallen into a cask of honey, was sought for some time unsuccessfully, until Polydius, a soothsayer, who came from Argos, discovered where he was immured. Minos finding this Polydius to be so cunning a personage, believed that it was in his power, if he were put upon his mettle, to restore the young Glaucus to life, and accordingly ordered him to be shut up in the same cask with the dead body for the purpose of inducing him to make the experiment of re-animation. While thus confined with the corpse, and finding himself without resource, he perceived a serpent approaching him which he immediately killed; soon after another serpent came; and, regarding the dead body of the first, immediately went out, and returned forthwith bearing a certain herb with which he covered the dead body of his fellow, and thereby restored the animal to life. Polydius directly tried the same experiment on the dead body of Glaucus, and with the same effect.

7. This well known story, taken from Hyginus and Apollodorus, Le Clerc follows up by another, which, as having in it a little less of the marvellous, is of course entitled to a little more credit. Melampus while performing the duties of a shepherd, having observed that his goats were purged while they fed on hellebore, ordered the milk of these goats to be administered to the daughters of Prœtus, who imagined themselves transformed into cows; the milk proved purgative to them, and they were cured by it of their hallucination; and hence has been traced the origin of an opinion which came to be general, that hellebore was not merely a cathartic but that it possessed some specific influence upon disorders of the mind.

8. In another part of his history Le Clerc alludes to the story told by Pliny respecting the hippopotamus, or sea-horse, drawing blood from his body by means of a reed, thus relieving himself from a plethora, and thus teaching man the art and benefit of artificial blood-letting; and to the account further of the bird ibis administering enemas to itself with its own bill; and having recorded these with other narratives and intimations, he concludes with the following judicious remarks. Besides that fable is more or less founded on fact, every one knows by his own observation on others that the condition of health is greatly referrible to matters whether of diet or luxury taken out of the ordinary course of things; and, if accidental observation be thus capable of teaching the deleterious qualities of certain substances, the same observation would be likely to lead to the discovery of salubrious substances. Thus mankind would come successively to observe, to reason, and to generalise, and thus would experience and experiment in the art of healing be gradually systematised into a science.

9. We may here incidentally remark, before we proceed with our history, that the simplicity of primeval medicine, and its present condition among savage tribes, have been preferred as arguments against the necessity of its complication; in other words it has been urged that the ancients with their herbs and simples did quite

as well as the moderns who have brought into subserviency the other kingdoms of nature, and have converted medicine from a matter of mere observation and simple inference, into one of extensive reasoning and complicated induction; but objectors of this kind, even if we allow their correctness as to fact, overlook the circumstance of artificial states engendering artificial wants, and that as law, from a simple consideration of right and wrong, branches eventually out into code, and precepts, and acts, so does the necessity of medicine's complication increase with increasing luxury, and become complicated to meet the complicated demands of artificial existence.

10. As, however, medicine was first 'cultivated by the patients themselves, or by their friends and relations, it becomes a matter of interesting investigation to trace the successive steps by which it proceeded from general to particular cultivation; and to develope the causes and circumstances which have in the course of ages advanced the science and profession to the rank and importance which they now assume and maintain.

11. It must be recollected, as a matter of importance connected with this enquiry, that in the very earliest ages, and before the physical sciences had made much progress, events were often considered as having received a satisfactory solution, in respect to their rationale, by referring them to divine interpositions; no one, indeed, even in the present day, ought for a moment to question that an interposing providence regulates the affairs of the world, but we do not now talk of 'the darts of Apollo' when we contemplate the consequences of a heated atmosphere on the Trojan marshes. But, when such was the mode of settling the matter, it is easy enough to conceive that the first men, who came as a distinct order of men to take cognizance of disease and its management, would be those who were the professed media of communication between heaven and earth.

12. 'The priests,' says Cabanis, 'soon seized upon the province of medicine, and found it no difficult matter to combine it with their other instruments of power. Indeed, the medical and the sacerdotal professions have in reality many features of resemblance. Both bring into action the same principles, hope and fear; and, although the objects of these two passions are not the same in the hands of the priest as in the hands of the physician, their effects had, at that time, nearly the same degree of influence in promoting the views of both. Certain it is that medicine, like superstition, exerts on the minds of men an influence proportional to their weakness; and, as the former acts upon more real and palpable objects than the latter, it is found that the most rational and enlightened men can never entirely resist its power. In short, no art penetrates further into the human heart; no profession enables its votaries more easily to obtain possession of the most important family secrets; no species of doctrine (except that, indeed, which relates to the agency of invisible powers) affects so nearly all those fanciful ideas in which the human mind, when it throws off the restraint of reality, is so apt to indulge; and certainly none furnishes means more independent of all political revolution, to those who impose upon the credulity of the public, and cultivate it, like a fruitful soil, with the utmost care and attention. It was, therefore, natural that the priests should become physicians, as they in fact became; and in most savage tribes the art is still practised by the priests or by mountebanks.

13. Egypt was the cradle of medicine as it appears to have been of every other science; and we hear of Thoth, or Thouth, whom the Greeks have called Hermes, and the Latins Mercury, but about whose actual existence there seems to be some doubt: and the same may be said of Isis and Osiris, which were perhaps rather regal titles and allegorical representations than real existences. At any rate, their history is so mixed up with fable, and one is in such a manner confounded with the other, that very little of satisfaction can be obtained with respect to them as cultivators and promoters of the healing art. Some have attributed the invention of medicine to Horus, son of Isis, who was the Apollo of the Greeks, and about whom the early historians speak as a real person. It is to this Apollo that Ovid alludes in his Metamorphoses, making him call himself the inventor of medicine and the subjector of plants to his power in the following well-known lines:—

Inventum medicina meum est, opiferque per orbem
Dicor, et herbarum subjecta potentia nobis, i. 521.

14. Æsculapius was called by the Greeks the son of Apollo, and we find a great deal, both in the historians and poets of the early periods, of allegorical and metaphorical matter mixed up with the accounts respecting the circumstances of Æsculapius's birth and elevation. Certain it is, that, for a long time, he acquired the ascendancy over medicine and medical rites; and the priests, who were still the physicians of the time, acted in the assumed capacity of priests of Æsculapius, and invented charms and effected cures avowedly under this assumption.

15. Temples were erected in different parts of Greece, dedicated to Æsculapius, now deified, and from these temples oracles were issued by the officiating priest, as if emanating from the resident and presiding divinity; these oracular emanations were usually conceived and issued in such sort as to establish their prophetic and operative power in the event of success, and to be susceptible of a double signification, so as to elude exposure, or conceal the imposition, in the event of the prediction not being fulfilled. And in spite of the doubts of the philosophers, and the occasional ridicule of the satirical writers of the times, the mass of the people resorted to the Æsculapian temples under the full feeling of belief and expectation; and often returned, satisfied and cured, from the very circumstance of their faith keeping pace with their wishes.

16. We are told, moreover, that the air respired in the country, and surrounding the Æsculapian temples, was naturally pure, from the elevation of the soil, and was rendered still more salubrious by the woods which encompassed them. These woods themselves became also the objects of religious veneration; they were preserved with great care; and their sombre shade

[illegible] the [illegible] their [illegible] [illegible] en-[illegible] which seemed to be more [illegible] to them. For an [illegible] would have been very insufficient [illegible] his advice did not [illegible] it was at least becoming that the patients should [illegible] In consequence [illegible] this [illegible] must have been accomplished by [illegible] which the patients experienced in [illegible] in the temples; by an [illegible] they had been but [illegible] consequences [illegible] effects [illegible] produces upon man, [illegible] upon the generality of animals; and [illegible] effects of [illegible] a certain descrip-[illegible] who possess more cunning [illegible] himself in [illegible] influence of which left [illegible] and he maintained [illegible] better, [illegible] less [illegible]

17. The temples of Æsculapius, continues the author from whom we are now extracting, were very spacious, and within their walls were convenient lodgings for the priests; but, as the deity did not permit any person to die within them, which certainly would have been very inconvenient, those persons who were afflicted with severe disorders, and women in the last stages of pregnancy, were obliged to remove to the neighbourhood, and they often remained in the open field, exposed to all the injuries of the weather. The deity also forbade any part of the offerings and sacrifices to be consumed out of the temples. From this regulation, which was no doubt, very politic, we see that he was both wise and provident, and had the welfare of his ministers no less at heart than his own fame and character.

18. Of the great number of temples dedicated to Æsculapius the most celebrated were those of Epidaurus, of Pergamus, of Cos, and of Cnidos. The temple of Cos was burnt in Hippocrates' time. The walls and pillars of it were covered with inscriptions, briefly describing the history of diseases, and giving an account of the remedies which had been successfully employed for their cure according to the advice of the deity. People of affluence had these inscriptions engraved on marble, on metal, or on stone; the poorer sort had them carved on mere tables of wood. However imperfect these descriptions of diseases, and of the methods of cure, may have been, their collection was nevertheless very valuable. They formed, as it were, the first rudiments of the art; and discovered some faint traces of the method of observation and experiment which alone is capable of placing it on a solid basis.

19. In contemplating the circumstances and particulars connected with and characterising ancient medicine, we are disposed to think that the whole was imposition on the part of the agents, and credulity on the part of the people; but it may be questioned whether the Æscula-pian [illegible] and priests did not act as much under the influence of self-deception as that of deceiving the multitude; and, indeed, when they found crowds of votaries returning from their visits to the temples, with their faith confirmed and their maladies healed, it was natural enough, in these early times of fanaticism and unbounded belief, that they should come to believe themselves what the people supposed them to be, immediate interposers between them and deity. Knavery is often supposed and charged, even in modern times, when the fact has been that the individuals thus charged have been acting under the influence of somewhat better motives than those supposed to be in operation. The facts connected with the history of our late prophetess, Joanna Southcott, were sufficiently humiliating and extraordinary; but it is far from impossible that even this woman was quite as much a fanatic as an impostor, and that she was worked upon by the faith of her followers, so as to actually suppose herself what her disciples gave her credit for being. In any other point of view than that of fanaticism and delusion, it is difficult to realize the systematic procedure of the priests in ancient times with regard to their profession of miraculous powers.

20. In Egypt then, in the first instance, and subsequently in Greece, medicine was practised alone by the sacerdotal orders; and this was in fact the case among the Israelites; we find in sacred history that the Levites were the persons consulted respecting the management of leprosy and other disorders incident to the age and people, and in the porch of the temple of Jerusalem a complete formulary of remedies was exhibited, of which Solomon was said to be the author.' The Essenes, a sect celebrated for the pure and mild system of morality which they endeavoured to propagate among a wicked and hypocritical people, cultivated the science of medicine, not only in order to render themselves more respected, but also in order to discover means to improve the minds of their adherents by rendering their bodies more healthy. Zealous apostles of their doctrine they endeavoured to confirm it by the performance of cures; and by these means they were often enabled to brave the jealous furies of the Pharisees, those hypocritical and domineering priests. They went sometimes by the name of Essenes and sometimes by the appellation of Θεραπευται, which signifies healers or physicians.'

21. Chinese pretensions to antiquity always defy any attempts to follow them; but there were some practices among these people of exceedingly ancient date which have been resumed in modern times such as acu-punctuation; and among the Babylonians and Chaldeans a great deal of their medicine was connected with astronomical investigations that characterised these people. Herodotus, however, speaks of the sick at Babylon as being exposed in public places to the inspection of passers by, who were solicited to give them advice and furnish them with means of cure; so that part of the medicine of these ancient people consisted in something more palpable than astrological influence, or mere calculations from planetary positions.

22. From the hands of the priests, medicine fell into those of the philosophers. Certain men, of a noble character and more sound understanding, soon began to direct their attention to the study of the rising arts. At first they employed themselves with those which related to their immediate wants. The science of public and private morals was doubtless regarded by them as belonging to this class; and accordingly we see them employing their utmost sagacity in the research of its rules, exerting the strength of their judgment in their delineation, and inculcating with all the commanding powers of their eloquence the advantages which accrue, both to individuals and society in general, from a rational but entire obedience to those immutable laws. Natural philosophy, astronomy, and geometry, which sciences were all in their infancy, became at the same time the objects of their contemplation. From this investigation, superficial as it no doubt was, of the different classes of natural phenomena, they acquired the habit of a certain method in their proceedings, which soon became a sort of necessary want to them.

23. When these sages afterwards came to turn their attention to medicine they were able to throw a new light upon the science. Accustomed as they had been to arrange in a certain order the different branches of their knowledge, to trace relations between them, and to connect them together, they perceived how requisite it was to class the indigested mass of medical observations, before they could be subjected with advantage to the test of reasoning. And if, on the one hand, in order to discover some connecting principle among so great a number of facts, it was absolutely necessary to resort to classification; on the other hand it was no less requisite to impress the conclusions which were obtained firmly on the memory, to arrange them, and to express them in the form of general rules.

24. The revolution which these early philosophers effected in the medical art was evidently a work of necessity. The time was come for drawing it forth from the recesses of the temples, and for dissipating at least in part the obscurity in which ignorance and quackery had involved it. If these attempts had done nothing more than bring it fairly to light, they would still have the merit of greatly contributing to its progress. From that time forward, a rational system was substituted in the place of undigested collections of rules; enterprising geniuses began to connect the principles of the science with those of the other branches of human knowledge; and its intimate relation to the different parts of natural and moral philosophy became every day more apparent to minds, whom books could not yet mislead from the path of pure observation.

25. These philosophers then freed medicine from its superstitious and hypocritical character. They transformed an occult and sacerdotal doctrine into a popular science and a common art. This reform was of infinite service both to medicine and philosophy; but it must be confessed that its happy effects were in some degree combined with serious disadvantages. For, in remedying errors, the reformers often fell into a dangerous extreme; not satisfied with applying to medicine that general and sublime species of philosophy which presides over all the sciences, and which alone is capable of illustrating their principles and operations, they vainly attempted to transfer to it the imaginary laws of their systems of natural philosophy, and various other conjectures which were the most fertile sources of error when thus applied, that the particular objects to which they related had absolutely no connexion with the living system.

26. Thus Pythagoras endeavoured to explain the laws of the animal economy, the formation of diseases, the order of their symptoms, and the action of medicine by the power of numbers Democritus again referred them to the motions and different relations of figure and position of the primary atoms of matter, while Heraclitus attempted to account for them by the various modifications of which the ovative and preservative fire of the universe is susceptible. It was but natural that the hypothesis which each of them employed for illustrating the production of animated bodies should be also applied by him to explain the series of phenomena brought to view by their spontaneous evolutions, by the agency of external substances, by the changes of which they are susceptible, and by their final destruction, or that alteration of form which we call their death. Hence arose so many futile theories of which we may find examples in the works of Plato, Aristotle, and Plutarch, and from which the writings of Hippocrates himself are not wholly exempt. Empedocles, for example, the disciple of Pythagoras, affirmed that the muscular flesh was composed of the four elements combined in equal proportions; he supposed the nerves when cooled by the external air to form the nails; he thought the perspirable matter and tears resulted from the fusion of the blood, and imagined the osseous matter of the system to proceed from the union of earth and water. Timæus of Locris framed a new system of cosmogony, from which he deduced his physiological views and methods of cure. Eudoxus, Epicharmus, Democedes, &c., adopted the opinions of the Italian school founded by Pythagoras, and their system of physic was supported and guided by that philosopher so celebrated, and yet so little understood, even by the ancients; but for which, when we consider its beneficial effects in a moral and political point of view, it is impossible not to be inspired with sentiments of veneration.

27. To conclude: all men of letters, whom a sedentary life and the nature of their labors disposed to melancholy habits, cultivated medicine as a subject of meditation upon themselves. Their habitual valetudinary state obliging them often to invoke its assistance, they had the additional motive of the proper care and preservation of their own health to invite them to the study. Their first acquirements, superficial as they often were, could not fail to prove in active minds the germs of numerous errors. Those among them who did not combine the observation of diseases with their theoretical opinions, such as they had been delivered in the schools by oral communication, or detailed in the small number of written works which existed in those

early times, allowed themselves to be easily deluded by romantic notions; and the custom of ranging and systematising all their ideas rendered their errors more serious and dangerous.

28. Of all the philosophers, who at that time devoted themselves to the study of medicine, no one preserved himself more free from the spirit of hypothesis than Acron of Agrigentum in Sicily. This bold and original genius, whom the empirics of later times have regarded as their chief, was desirous to refer the art of medicine to experience alone. Accordingly, he reduced all the reasonings about disease to the appreciation of the different symptoms which admitted of comparison, and to the discovery of analogies from which he observed that we may often draw the indications of cure. But, although he enjoyed a high reputation in his life time, his opinions could not overcome the ascendancy of more positive and dogmatical theories; and it was not till long after that they became the rallying point of a sect of respectable physicians. Although, too, these opinions were less dangerous when applied to practice than those of his opponents, it is but too certain that a spirit of rivalship carried the adherents of both almost equally far beyond the bounds of reason, which indeed would have easily reconciled them, for the dispute turned, properly speaking, upon mere words.

29. The philosophers of antiquity then both improved and injured the science of medicine. They rescued it from undiscerning ignorance, but they precipitated it into a variety of hazardous conjectures; they delivered it over from the blindness of empiricism to all the rashness of dogmatism. In short, its lot was the same as that of moral philosophy. Medicine at first, as placed in the hands of the poets, exhibited only an assemblage of beautiful images or refined sentiments; while, in the hands of the priests, it adopted the vague language and mysterious tone of superstition; and, in the hands of those primitive philosophers whose exertions in other respects claim our warmest acknowledgments, its scattered, confused, and undigested materials were combined and formed into more or less regular, and more or less perfect systems; but it usurped the principles of many other sciences which were themselves but in a crude state; it shared in their errors, which proved the more injurious to it, as these sciences had for the most part little connexion with it. We may even venture to assert, that it made in some measure the complete round of the false systems which prevailed in the different branches of human knowledge, and which succeeded each other by turns (Cabanis).

30. We have made this long extract from a modern author, because we think that he has in a happy manner, traced the circumstances of directing the succession of medicine from that of being a symbolical and poetical matter in the first instance, and afterwards a sacerdotal concern, into the hands of those men who were named philosophers in consequence of their seeking to divine the causes of things, and looking deeper than the vulgar into the principles of material phenomena.

31. But philosophers full of desire to penetrate into the secrets of nature, and engaged in investigations on the subject of abstract truth, were likely enough to prove bad physicians on two grounds. In the first place they could not be supposed to have time or disposition to attend minutely to those details which practical medicine demands; and in the next it is in the very nature of philosophical speculation to force analogies into the mind that are of the most fallacious nature. Medicine, then, first in the hands of poets and priests, and subsequently cultivated by men of general science, awaited the birth of a superior mind who should as it were stamp a peculiarity on its pretensions, and learn, and teach, and practise it as a distinct and separate branch of pursuit.

32. It was this which the far famed Hippocrates did for the science and art of healing, and on this account he has been styled the father and founder of medicine. Hippocrates was a philosopher before he was a physician; but finding, says Le Clerc, that the speculations of natural science were not so likely to benefit society as the practice of medicine, he only retained enough of his first pursuits to enable him to reason justly on the subject of medicine, which he at length made his principal or rather his only study. The original of our quotation runs thus: 'Mais ne jugeant pas que les speculations de cette derniere science (philosophie) fussent aussi utiles a la societé que la pratique de la premiere, il ne retint de la philosophie qu'autant qu'il en fallait pour raisonner justement dans la medicine, dout il fit sa principale, ou plutot son unique etude.'

33. Cabanis expresses the same fact in a more diffuse but in a pleasing and instructive manner. We employ in this instance the translated copy of the French author by Dr. Henderson. Surrounded from his infancy with all the objects of his studies; instructed in eloquence and philosophy by the most celebrated masters; having his mind enriched with the largest collection of observations which could at that time have existed; and endowed in fine by nature with a genius which was at once penetrating and comprehensive, bold, and prudent; he commenced his career under the most favorable auspices, and pursued it during a period of more than eighty years, with that degree of renown which was equally due to his talents and to the greatness of his virtuous character.

34. Euryphion had just published the Cnidian Sentences. Herodicus too by the revival of gymnastic medicine, the original invention of which was ascribed to Æsculapius, had given to the art a more regular and scientific form. They knew how to observe diseases, and were acquainted with the most general remedies, such as venæsections, emetics, cathartics, and bathing, the use of incisory instruments, and of the actual cautery or fire; and although a certain routine, numerous false theories, and the influence of superstition, continued to deform the prevailing methods of treatment, yet the glimpses of a happier dawn were perceived at intervals in almost all the branches of medicine.

35. It was in these fortunate circumstances that Hippocrates appeared as it were on a sudden, and procured to the Coan school a lasting pre-eminence to which it was doubtless well entitled, since it had been able to produce such rare talents. Amid the sports of childhood he received from the mouth of his parents the elementary notions of medical science; by viewing diseases he learned to distinguish them; by witnessing the preparations and employment of medicines, their use and their virtues became equally familiar to him. The first objects which strike the young and curious senses, the first comparisons which they suggest to the infant mind, the first judgments of growing reason, have a greater influence on the remaining part of life, as the traces which they leave, and the habits which they form, are for the most part indelible. It is then that the bent of the character, and the particular cast or direction of the operations of the mind, are determined. To the fatal disposition to satisfy ourselves with words, and to affix to those we employ erroneous or vague ideas of the things they were meant to express, may perhaps in a great measure be ascribed the custom of constantly figuring to ourselves objects which we have never seen, and of substituting the fictions of the imagination for the works of reality. A sound habit of judgment depends upon the justness and accuracy of the sensations; and the organs which are designed for the reception of the latter require culture, that is, a well directed employment. Now as nature or the objects surrounding us are our proper teachers, and as their instructions differ from those of men or books in this respect that they are always adapted to our faculties, they are consequently the only ones which are seldom or never fruitless, and the only ones which never mislead us. We must therefore in general early familiarise ourselves with the images which are destined afterwards to furnish the materials of all our judgments; and, with regard to each in particular, the man who devotes himself to it cannot place himself too soon among the objects of his studies, or in that situation which is the most suitable to the nature and design of his observations.

36. Hippocrates was not less favored by circumstances than by nature. The latter had endowed him with the most happy frame of body; the former furnished him from his earliest infancy with every thing which could most successfully contribute to his education.

37. Good sense, joined to the faculty of invention, is the distinguishing characteristic of a small number of privileged men. Hippocrates was of this number. He saw that too much and yet not enough had been done for medicine, and he accordingly separated it from philosophy, to which they had not been able to unite it by their true and reciprocal relations. He brought the science back into its natural channel, that of rational experience. However, as he himself observes, he introduced both these sciences into each other, for he regarded them as inseparable, but he assigned to them relations which were altogether new. In a word, he freed medicine from false theories, and formed for it sure and solid systems; this, he with justice said, was to render medicine philosophical. On the other hand he elucidated moral and natural philosophy by the light of medical science. This we may with propriety call with him the introduction of one into the other. Such then was the general outline of his plan.

38. The fame of the existing schools (says Dr. Parr in his Medical Dictionary) was soon eclipsed by Hippocrates, who seemed to have been the first to whom the appellation of physician in its modern acceptation is due. He first separated it from philosophy, gave it the form of a distinct science, and personally observed the progress of disease as well as the effects of remedies; on this account he is esteemed the inventor of the medicina clinica. Yet perhaps the philosophers who preceded him must not be wholly omitted. We are reminded of Pythagoras, by the Climacterics, by the critical days, and his recommendation of vinegar of squills in deafness; of his scholar Alcmæon, who first described the eye; of Empedocles, who, before any other anatomist, dissected with accuracy the ear; and of Timæus Locrus, who taught that the nervous system was the basis of the whole body on which the nutritious system was gradually extended. Democritus was rather a philosopher and a chemist than a physician, and might have ranked with credit in each class, were the various hints of his labors collected.

39. Of Hippocrates, continues Dr. Parr, it is difficult to speak impartially in a manner that will satisfy his warm admirers, or those who reject every thing that is not of a modern era: and if we look at him as a physician when medicine had scarcely escaped from the trammels of superstition, the refinements of philosophy, or the dictates of antiquated tradition, our admiration will rise almost to enthusiasm; for we shall perceive sound judgment, accuracy of reasoning, and acuteness of observation, superior to his era or the state of science at that period. But to study and admire Hippocrates at this time is very different. Science has opened newer and more extensive views, diseases are distinguished with greater accuracy, and the remedies as they are more numerous may be more appropriately adapted to the circumstances. If we find a striking description in Hippocrates we admire it as a mark of superior genius, and wonder how the same event could have happened both in Greece and England. Yet strip the fact of the disguise of system and it will be found that patient observation would alone have taught it. He fills however so vast a space in the medical scene that some further notice of him and his doctrines will be necessary.

40. Hippocrates was born in the first year of the eightieth Olympiad, 460 years before the birth of Christ, and was descended from a line of physicians, inheriting the instructions of his father and grandfather, themselves descendants from the Asclepiadæ, while his mother traced her origin from the Heraclidæ: he died at Larissa it is said at the age of ninety. He first practised physic at Thasus, afterwards at Abdera, and at last in Thessaly; but his chief residence was at Cos, where the Coan school became for a long

time the successful rival of the Cnidian. All that has been added to these few events is doubtful. That his instructors were Herodicus or Prodicus, and Democritus, rests only on the attention which he has paid to the gymnastic art as well as to anatomy; and the philosophy of Hippocrates is more nearly allied to the tenets of Heraclitus than of the Abderite. As Hippocrates was a great traveller, he might have attended the lessons of Prodicus in Athens, where he chiefly taught; and might there have been acquainted with his brother Gorgias whom he afterwards attended in his medical capacity in Thessaly when worn down with oldage; but we have no records of his having ever practised at Athens.

41. It is not very easy to form a true estimate of the anatomical knowledge and physiological science of Hippocrates. Some of these subjects are treated of in works which are attributed by some to him, and by others are deemed spurious. Le Clerc, however, has taken pains to distinguish these; and the following outline will be very little else than an abridged translation of the work of that learned and laborious author.

42. The doctrine of the four primary qualities of heat, cold, moisture, and dryness, seems to have been held by Hippocrates, and of the primary elements air, water, fire, and earth: he also supposes, and reasons upon the supposition of a leading principle to which he gives the name of nature, about the operations of which he occasionally speaks somewhat vaguely, but in consistency with the spirit and temper of the times, which too much confounded the ideas of final with physical or efficient cause; and which supposed the invention of a term the development of a principle. Indeed if we are to believe the treatises de Flatibus, de Carnibus, de naturâ Hominis, de naturâ Pueri, and de Dietâ to be the productions of Hippocrates we must believe that some of his positions respecting the formation of the hard and the soft parts of the body, from the different elements and qualities and principles in nature, to be of the most whimsical and futile kind.

43. With respect to the anatomical researches and science of Hippocrates it appears, to say the best, very doubtful whether he ever actually witnessed the dissection of the human subject. In the book de Alimento we find it stated that the veins originate in the liver, as the arteries do from the heart. In another part he talks of two orders of vessels proceeding from the heart, namely, the veins and the arteries or rather the roots of these as single vessels. At this time, indeed, the word vein was generally applied to vessels containing blood, and artery to those which were supposed to contain air, Αρτηρια, απο του τον αερα τηρειν. In the description of the heart ascribed to Hippocrates we find it stated that the organ is of a pyramidical figure, of a red color, that it is every where enveloped by a tunic, between which and the heart's substance a small quantity of water is found similar to the urine, that it is a strong muscle, that it has two ventricles, and that it has internal membranes of an admirable structure. And, when he passes from description into the physiology of the heart and connecting vessels, we find some faint intimations of a circulatory movement: all the veins, he says, have a general communication, by which communication nourishment is conveyed through the whole body; and he further supposes or speaks of a rest of vessels—which, say his commentators, necessarily imply the notion of movement or circulation. It is curious that, when adverting to the return or reflux of the humors from the surface to the centre of the body, he makes use of a word which was employed to express the motion of the tides, αμπωτις; from which it has been fairly inferred that Hippocrates although not fully acquainted with the transmission of the blood from, and its return to, the heart, had some faint impression or vague notion that such exit and reflux was effected; indeed the more enthusiastic admirers of the great man concerning whom we are now speaking have not hesitated to say that the modern doctrine of the circulation was known to him; but it is evident, and Le Clerc very properly insists upon this fact when discussing the question, it is evident that this flux and reflux was considered by Hippocrates as effected by the same order of vessels; and the way altogether in which the subject of the motion of the blood and humors is spoken of has a confusedness and vagueness of manner, which is very different from the precision and clearness of the present day doctrine.

44. Neurology, or the doctrine of the nerves, as taught by Hippocrates, was perhaps still more vague and indistinct in reference to its comparison with the physiology of modern times. Nerves, tendons, and ligaments, are evidently confounded together in his writings; and with respect to the brain, and its connexions with other parts of the body, we do not find any thing upon which the modern anatomist can rest with much pleasure, or which modern physiology can recognise as clear and distinct. Hippocrates places the brain among the glands, inasmuch as it appears of the same nature with other glandular substances, being like the glands generally white, and friable, and spongy; and he supposes that the brain charges itself with the superfluous humors of the body as do the other glands, being as they are spongy, and therefore capable of easily absorbing. He moreover imagines its power of absorption from its form and situation, and considers it to be attractive of the body's moisture, which rises into it as vapor, until such time as it becomes surcharged, when this moisture is again transmitted to different parts of the body, more especially to the glands, whence come fluxions and catarrhs.

45. With respect to the other uses of the brain, Hippocrates speaks of it in some of his writings, in his book de Morbo Sacro, for instance, as the seat of understanding and wisdom; although in other places, as in his book de Corde, we find the seat of understanding (γνωμη) lodged in the left ventricle of the heart. It should be observed that our author speaks of two membranous coverings to the brain, the one thick and the other fine in its structure.

46. The organs of sense are described by Hippocrates in the following manner:—The ears have a hole which penetrates as far as a dry and

hard bone, to which is united a fistulous cavity, or an oblique kind of canal, at the entrance of which a very fine and dry cuticle is found, the dryness of which as well as that of the bone produces sound; the air being beaten back as well by the bone as the membrane. On the organ of smell he thus expresses himself:—The brain being moist possesses the faculty of sending out an odor, or of smelling, by drawing the odor of hard materials in with the air which traverses certain dry bodies; the brain itself extending into the nasal cavities. In this organ we find no bone as in the ear, but merely a cartilage similar to a sponge, which cannot well be considered either bone or flesh. When treating of the eye, he speaks of small and very delicate veins which are conveyed into the organ by means of a membrane which envelopes the brain. These veins carry to the eye a very pure humor which comes from the brain. There are, he adds, three membranes enveloping the eye itself; the outer one the thickest, the middle one the most tenuous, and the third which preserves the humidity or the humor of the eye is very loose. If the first be injured the eye is affected, if the second is torn or broken it places the organ in great danger, and it projects like a bladder; but the third is the membrane an injury to which is the most mischievous, on account of its office being that of preserving the humor. The rationale of vision is accounted for very obscurely, and a vein is talked of as being sent from the membrane of the brain and conveying a humor which forms diaphonous, and reflecting membranes. It is very obvious, from the mode in which our author expresses himself in reference to these points, that he had no proper conception of the transmission of the optic nerve; and that he confounds the notions of nerve, and vein, and membranes, and humors, in a way that is any thing but precise and clear anatomy or physiology.

47. The muscular fibre and flesh are likewise described with considerable vagueness; he describes the œsophagus as a tube which extends from the tongue to the stomach; the stomach itself is spoken of as a paunch in which the septic process goes on (Κοιλιη σηπτεχη), or where coction (πεψις) takes place; this coction or digestion being effected, according to him, by the heat of the stomach, which he describes as connected with the liver from which proceeds the necessary heat. It appears that Hippocrates only talks particularly of two intestines, the first attached to the stomach twelve cubits long, always folded and suspended by the mesocolon, which is itself attached to the nerves, which come from the spine of the back, and which pass under the abdomen; the second intestine is covered with a good deal of flesh, is porous, and terminates at the anus.

48. The liver is described as more abounding in blood than the other viscera, and as having two avenues or gates; he talks of its division into five lobes, and as being the origin of the venous system. He speaks of bronchiæ as passing from the heart to the liver, together with the great vein of the organ. He assigns to this organ, the liver, the office of separating the bile, and, as we before remarked, supplying the stomach with heat.

49. The spleen is spoken of as similar in its form to the impression of a man's foot, and as receiving a vein which ramifies into its substance. The organ is, he says, suspended by the omentum which it supplies with blood. He says that it is fibrous, soft, and spongy, and that it draws from the stomach by its spongy consistence part of the fluid from the stomach, to which it is attached; the rest of the fluid being attracted by the urinary bladder.

50. The lungs, according to Hippocrates, have like the liver five lobes; they are spongy, and attract moisture from neighbouring parts. The diaphragm is named by him φρενες, under the notion that it was the seat of intelligence, dividing as it were this locality with the heart; but this office was not universally ascribed to the organ in question, even during the life-time of our author, and it is even contested in a work which has been attributed to Hippocrates himself.

51. The kidneys are placed, by Hippocrates, among the glands; he speaks, as we have above intimated, of their attracting part of the fluids of the stomach. The vesiculæ seminales are mentioned as bodies lying on each side of the urinary bladder, and containing the semen. The organs of generation are rudely delineated in either sex; and the mode in which conception and gestation are effected is traced in a very fanciful and hypothetical manner. We may probably have to allude to our author's notions on these particulars in the article PHYSIOLOGY.

52. When considering the general principles of health and disorder, Hippocrates refers to the four supposed humors, viz. the blood, the phlegm, the yellow bile, and the black bile; the impulse or moving power of these several humors being a spirit, which partakes of the nature of air. The above four humors existing in due proportions, constitute health; disease resulting from a disproportion in either one or more, or an undue impetus in the motion of one or the other, occasions disease without reference to change of quantity. The excitants of disease are air, food, and drink, sleep and watching, exercise and repose, things which are expelled from the body, those which are retained, and the passions of the mind. He also speaks of the reception of exterior substances, as of poisons and venomous animals; but the principal source of disease, according to our author, are aliments and air. Both on the subject of dietetics and of air, Hippocrates therefore treats largely; and, in conformity with the spirit of the times, he supposes heavenly influence to have a share in the immediate production of certain maladies, but it must be admitted that he gave as little as possible into the superstitious notion of celestial workings; and indeed in the book De Morbo Sacro it is expressly stated that we ought not to attach the idea of divine origin to one disorder more than another, for all maladies are in one sense divine, and in another human. Respecting, however, the authenticity of this book, there are, as before stated, some doubts.

53. The modern distinction of diseases into chronic and acute was observed by Hippocrates, and he distinguished them moreover into endemic, or those which are peculiar to a people; epidemic, or those which visit masses of

people in a district at certain times; sporadic, or maladies of different characters affecting a people at the same time; and hereditary, or those disorders which are born with us, and have been transmitted by parents.

54. Crisis and critical days are largely dwelt upon by Hippocrates. He talks of the terminations of diseases as being regulated by the concoction of humors, and of the modes which nature employs to expel these humors from the body after due preparation.

55. The critical periods of our author are formed considerably upon the Pythagorean notion of numbers, and he speaks of every fourth day as having something in it of destinating or regulating power. In disorders which he would call exceedingly acute, the coction of the humors becomes completed and the crisis perfect on the fourth day; the ordinarily acute disease may pass on to the seventh, and sometimes to the eleventh, or even to the fourteenth; occasionally he talks of acute diseases being protracted to the twentieth, or one-and-twentieth day, and at times even to the fortieth and sixtieth: after this last period the disorder is considered as justly entitled to be ranked among chronic affections.

56. After the time of critical tendency is over, in reference to days, Hippocrates supposes the seasons and other circumstances to influence the termination or protraction of disorders; some, for example, terminate about the equinoctial, others about the solsticial periods; others are regulated by the stars and constellations; and there are affections which are influenced by entire months and years; thus certain disorders, incidental to infancy, have reference to the seventh month from birth, and others to the seventh or fourteenth year.

57. Hippocrates does not argue for the absolute necessity of crisis in disorders, but he contends that the termination of acute maladies without them is not so safe and satisfactory as when they have place. He further recognises and speaks of the mutation of diseases, as when inflammation of one part or organ leaves the place originally affected, and falls upon another; or as when cancer of the breast is changed for cancer of the womb.

58. On prognosis and diagnosis the writings of Hippocrates are exceedingly full and particular. He especially speaks of the physiognomy as indicative of danger or otherwise; and his statement respecting the appearances of the countenance, in an individual who is about to sink under the violence of a disorder, has become proverbial. The Hippocratic visage is talked of even in the present day. When, he says, the nose is sharp, the eyes are sunk, the temples hollow, the ears cold and drawn back, the skin hard, extended, and dry, and the color of the face approaching to a leaden appearance, death is certainly approaching; to these signs he adds hanging, relaxed, and cold lips. He takes special notice of the appearance in the eyes. When a sick person is incapable of supporting the light, when he sheds tears involuntarily, when, during sleep, he shows part of the white of the eye, should that not be his habit, or he has no diarrhœa upon him, things are for the most part in a bad state, the last being a particularly unfavorable symptom. A want of the usual brightness of the eye is either a sign of approaching death, or indicates extreme feebleness. A sharp, fixed, and at the same time wild look in the eyes, denotes present or approaching phrenzy. When the individual sees red sparkling or clear bodies floating before his eyes, a nasal hemorrhage may be anticipated, or some critical loss of blood.

59. The manner in which the sick lie in bed is especially marked by Hippocrates as demanding and deserving observation. If the patient lies on one of his sides with a slight curvature, as in health, we may judge favorably of his state; on the contrary, if the individual lie on his back, with the arms and the limbs generally extended, and particularly if he is found gradually to slip down towards the bottom of the bed, a motion which proves that the body is as it were acting by its own weight without any muscular resistance, approaching death may be calculated on. Lying on the abdomen, should this position not be the common one, indicates either delirium or pain in the belly.

60. When an individual who has a fever upon him is continually picking with his hands and fingers, and often putting his hands about his face and eyes, as if to remove something that is irritating him, or pulling about the sheets and coverlet of the bed, as if to take things away that are offensive to him, delirium and death may be predicted; the approach of delirium is also menaced by the circumstance of a person, naturally taciturn, becoming talkative; or, on the contrary, when a great talker becomes all at once silent and reserved.

61. Starting of the tendons (subsultus) is marked as an especially unfavorable omen.

62. Frequent or oppressed respiration is a bad sign, as are continued watchings or want of sleep.

63. The color, the odor, and the consistence of the excrements, are matters of importance to attend to: if the fæces are soft, of a reddish brown, and of due consistence, answering in quantity to the ingesta, and evacuating at accustomed times, and not of an uncommon odor; the symptoms in reference to this particular are favorable; the fæces ought also to increase in consistence as the disorder approaches a crisis. Liquid motions may indeed be considered as importing well, providing they are not discharged with much noise, and not rendered in very small quantities, and very frequently. All watery evacuations from the bowels, whether of a white, or very high color, or of a greenish cast, or frothy, or nauseous, are bad. But the worst sort of fæcal discharges are those which are black and greasy, and those which are of a verdigris color. That discharge which is actually black, and which Hippocrates considers to be black bile, invariably denotes a very high degree of danger. Indeed, bile discharged in any form unmixed with fæcal matter is always a bad symptom.

64. In respect to the urine, that is to be considered the best which readily throws down a sediment of a whitish and equable kind; the notion of Hippocrates in regard to such urine is that this regular sediment denotes a disposition to what he calls, as above intimated, the coction of the humors. When, he says, the urine is

cloudy, and does not show a tendency to become clear by throwing down a sediment, the humors are in a crude unsettled state. When it is unusually white and clear, a very considerable crudity is denoted, and sometimes a transfer of the bile to the brain. Urine which is particularly yellow or red marks a superabundance of bile. Black urine is an exceedingly unfavorable omen, especially if its odor be particularly unpleasant, or if it be either preternaturally thick, or more than commonly clear. Those urinary discharges which appear to have in them a thick meal, or bran, or small bodies like scales or shells, are unfavorable, and denote a disorder in the bladder or the kidneys. Urine, upon the surface of which oily matter is found swimming, marks a disposition to consumptive wasting of the flesh. The sudden discharge of a copious quantity of urine is for the most part critical. The correspondence of the appearances on the tongue with the urinary discharge is pointed out by Hippocrates as capable of recognition, and important to recognize; if for example the tongue is yellow and charged with bile, the urine should be of the same color and condition; on the other hand, if the tongue is red and moist, the urine will be found natural in its appearance.

65. Matters discharged by vomiting ought to be mixed with bile and phlegm; those in which only one of these matters is present are not so favorable. Black, livid, and green discharges from the stomach are bad; and if they have a particularly strong odor, they denote approaching death. Vomiting of blood is often fatal.

66. Expectorated matter, or that discharged from the chest, is favorable in proportion to the facility with which it is thrown out; and, during the early periods of pulmonary disorder, it is not amiss to see that discharge of a yellowish tinge; but if this discoloration continues, or if the matter be acrid, and occasion violent cough, it is a bad sign. If the expectoration be quite yellow, it cannot be considered good; and discharges of a white, glairy, or frothy kind do not relieve the patient. White expectoration denotes a due coction, but then this whiteness must not be accompanied by viscosity, nor should the expectorated matter be either very thick, or very transparent. The same observations apply to discharges from the nose. Expectorated matter that is either black, or green, or red, is bad. But the worst sign in pulmonary affection is when the matter which ought to be thrown off from the chest is retained. Spitting of blood is followed by a discharge of pus, upon which follow consumption and death.

67. Perspiration is favorable when it happens on a critical day, when it is abundant and universal; but cold sweats are always unfavorable. If sweats are confined to the head and neck we may expect that the malady will be protracted and dangerous. Light partial perspirations either point out the seat of the disease, or denote topical weakness.

68. A soft equable condition of the hypochondria and the abdomen always imports well; if upon feeling over the abdomen any irregularities are found, or if one part is more hot than another, or painful to the touch, we may conclude that there is either external or internal inflammation.

69. With respect to the pulse, it is generally admitted that the remarks of Hippocrates do not correspond in precision on this head with those which are made in reference to other particulars. Some indeed have denied that our author recognised the pulse at all in the sense which we give to the term, that is the ordinary and natural beat of the arteries; and, with his confused ideas of the blood's flux and reflux, it is conceivable enough that the circumstance of pulsation would not by him be appreciated as it is in modern times; certain, however, it is, that in the books on Epidemics we read of frequent and strong pulses in acute fevers, and of the trembling, weak, and languishing pulse as indicative of approaching death; but it must still be allowed that on the subject even of fevers Hippocrates dwells much more upon all other symptoms, especially on the variation and degrees of heat, and on the kind of respiration (both highly important points of recognition) than he does upon the character and circumstances of pulsation.

70. We shall now consider the practice of Hippocrates, or the principles upon which he professed to treat diseases, as well as the remedies he was in the custom of employing; on these heads, however, we shall be proportionately less full than on the subjects of signs and prognosis, inasmuch as the maxims and remarks on these last are applicable to all times and all circumstances; while practical or therapeutical medicine varies with varied states of the art, and with the modifications made in disease by time and place.

71. Hippocrates gives the following general principles for regulating medical practice. We must proceed to oppose contrary to contrary; we must evacuate in cases of repletion, and supply materials where there has been too much loss. We must have recourse to heat in cases of cold; and meet superfluous heat by refrigerating measures.

72. We must recollect that there are certain juices or humors which require to be discharged or dried; others which are to be restored. We must be careful not to be very precipitate in our measures, either of depletion or repletion, either of discharge or restoration. We must not fearlessly and abruptly meet heat with cold, or cold with heat, nature being an enemy to every thing that is violent or in excess. We must sometimes contract and sometimes dilate, so as to give facility and freedom to the passage of the humors by the first operation, and restrain their too copious discharge by the second. There are occasions too in which we are called upon to sweeten, to harden, to soften, and to render parts finer or more subtle; sometimes we must give them increased thickness, at other times excite or stir them up, and occasionally it is necessary to blunt the sensibility of the body. It is expedient moreover to take good note of the natural tendency of the humors, and to follow nature as much as may be in her course, not to direct upwards what nature disposes downwards,

or to force in one direction where the natural disposition is to the opposite. We should be solicitous to choose convenient passages for discharges, and not permit matter which has been thrown out from vessels to return. Should we have attempted a course of proceeding without success, we must not be too quick in changing our plans of operation. We ought, however, to be ever watchful as to what obviously agrees or disagrees, or what the patient can and cannot support. Nothing ought to be undertaken rashly; and it is often the part of a prudent physician to stand still and merely watch, without any interference, since nature sometimes cures without the assistance of art, and, when we are doing nothing, we of course are avoiding positive mischief. In extreme disorders, Hippocrates proposes extreme remedies. What medicaments will not effect, may occasionally be effected by iron (cautery), and what this latter fails of performing may sometimes be accomplished by fire. At the same time, we must not think of uselessly interfering when the case is desperate, and beyond the powers of medicine.

73. In the detail of his practical directions, Hippocrates considers largely the subject of purgation, and he has a notion that the several articles which are employed as cathartics have the power of attracting as it were the particular something that requires to be thrown off, and thus effecting its expulsion; that having effected this main operation, of attracting the matter to be expelled, it subsequently takes hold of others; thus, if a medicine which is given for the purpose of purging off the bile is too strong, it takes hold first of the bile, then of the phlegm, then of black bile, and finally of blood. The purgatives employed by him were many of them of the active or drastic kind, such as hellebore, elaterium, scammony, colocynth, buckthorn, &c. The doctrine of concoction of humors, Hippocrates applies to purgative operations; and in some cases this preconception must have led him to erroneous timidity in respect to purgative medicinals, and, indeed we find some inconsistencies on this point; for in one place he talks of the propriety of purging at the commencement of acute diseases, while in others he speaks of its impropriety, till the humors are sufficiently prepared by concoction. Suppositories and clysters were employed by Hippocrates.

74. Bleeding, according to our author, should be instituted under several indications; in the first place, that of evacuation, or taking off a superfluous quantity of blood; in the next place, that of recalling the impetus of the fluid from parts where it is going in too large quantities; thirdly, to procure a more free motion of the blood and spirits generally; and fourthly, to cool the system. In those maladies which appeared to have their seat above the liver, he directed that blood should be taken from the arms, or from some veins in the upper parts of the body; while, in those disorders the locality of which was lower than the liver, he ordered the discharge to be procured from a vessel in the foot, or ankle, or ham.

75. The practice of taking blood by cupping is also spoken of, and directed by Hippocrates, both in the dry way, or without previous scarification, and also after scarifying.

76. When purging and blood-letting did not appear to avail sufficiently in diminishing the quantity of superfluous humors, our author had recourse to diuretics and sudorifics; sometimes simply ordering the bath or wine, to produce an increased flow of urine; at others, employing one or more of the diuretic species of vegetables, as garlic, onion, leek, fennel, &c.; but, when he wished for a more powerful diuretic operation, he administered cantharides, powdered and mixed with wine and honey. He scarcely mentions any particular sudorifics to be taken into the stomach, and in only one or two places alludes to the practice of provoking sweat, by pouring hot water upon the head. Υδατος πολλȣ και θερμȣ κατα της κεφαλης καταχεομενȣ.

77. In harmony with his doctrine of humors, Hippocrates talks of medicaments which increase or diminish dryness, or which resolve or dissipate humors, without actually purging; thereby indicating that class of remedies which would in the present day be called alteratives; and he speaks of drugs which procure sleep; of the mecon (μηκων) he speaks in several places, which was the poppy of the Greeks; but it is curious that he ascribes to this plant generally a purgative quality. There seems in this, as in the instance of hellebore and several other drugs employed by the ancients, reason to believe that the names have not been handed down to posterity correctly. Galen informs us that some considered the peplis and spatling poppy for the same plant; and he mentions, in his commentaries on Hippocrates, that meconium and peplis were often spoken of as the same thing. In addition to medicines acting thus sensibly, or upon certain principles, Hippocrates alludes to the specific virtues of drugs, or those which produce a particular effect without their modus operandi being at all known.

78. External as well as internal medicaments were employed by our author. Fomentations were employed in various ways; the first was that in which the patient sat in a decoction of herbs, so that the part affected should be as it were soaked by them; indeed this was a kind of medicinal bath. A second form of fomentation was that of enclosing hot water in a skin or bladder, or in a copper or earthen vessel, and applying the vessel to the part affected. Sponges too were employed for fomentation; and bran or vetches applied in linen bags. These applications were further made occasionally in the dry way, as by heated salt or millet in bags. Vaporous fomentations were also employed by Hippocrates, of which we find an example in the first book on Female Maladies. He threw bits of red hot iron into urine, and caused the patient to receive the steam from below. His intention in applying these fomentations was to warm, resolve, and dissipate; to draw out peccant humors, to assuage pain, and open or close pores, according as the materials employed were relaxant or astringent. Fumigations also were much employed by Hippocrates; and we find pitch, and sulphur, and other things, employed in this way for the purpose of bringing away phlegm from

the fauces, &c., in quinsies and other affections about the mouth and throat. Gargles too were used by him. And oils were recommended, in the way of friction, to mollify and ease pain, and resolve tumors. We find him farther speaking of ointments and cataplasms, both of the cooling and resolving kind. Powders were also employed externally, such as those used for resolving fungous excrescences, &c.

79. Pharmacy, or the art of compounding or preparing medicines, was evidently cultivated by Hippocrates; and it appears that he prepared medicines himself, or at least ordered their preparation in his own house by his servants; this indeed was common to the physicians of his time, pharmacy then not being, as it is now, a distinct branch of practice, but the physician being at once a practitioner in pharmacy as well as in surgery.

80. Before quitting our account of the medical practice of Hippocrates, we shall add that he gave particular attention to diseases of females, under the notion that the womb, according to one of his axioms, is the cause, or at least the regulator, of almost all disorders to which the female frame is obnoxious. Hippocrates, indeed, imagined that the womb was not only susceptible of relaxation and descent, but he thought it capable of being extended in several divisions up as far as the liver or the heart, and even the head. We find a great number of remedies specified, in his book on female diseases, for these supposed affections of the womb; and he made much use of pessaries, which were occasionally smeared with oily, or stimulating or aromatic substances, according to the indications of treatment. He also recommends injections into the womb in the case of ulcers of that organ, as well as in some other disorders of the part.

81. Hippocrates, as above intimated, was a surgeon as well as physician; indeed the latter included the former in these times, the arts not having, as we have also above stated, yet been divided. We shall, however, defer a history of the surgical precepts and practices of our author till we treat of SURGERY in particular; and shall terminate our account of the 'father and founder of medicine,' by extracting his maxims concerning medicine and physicians in general.

82. Medicine has long since been established, and, as many things have already been discovered, so are we put in the way of discovering several others, if we are fitted for the investigation, and follow the old track of observation. He who rejects every thing that has been already done, and branches out into a new road, boasts of having discovered novelties, but deceives both himself and others.

83. Medicine is the noblest of all arts; but it is one of the least respected on account of the ignorance of those who practise it, and of those who judge rashly concerning it. And what further injures the art is this, that it is the only one in which there is no other punishment beyond shame for those who abuse it, and those who thus dishonor it are insensible of shame. These individuals are a species of actors, representing themselves to be what they are not in reality: they are very numerous.

84. In this, as in other arts, there are good and bad artificers. The art is of great extent; life is short, opportunity easily escapes (οξυς), experience is deceitful, and judgment difficult. Not only must the physician do his duty, but it is requisite that the patient and those about him do theirs; and every thing, to insure success, must be disposed in the best order.

85. To arrive at a high degree of acquirement in medicine the following conditions are necessary:—A natural aptitude, opportunities of instruction, study and application from early life, a docile and well regulated mind, diligence, and time.

86. A physician ought not to be above learning from the meanest persons the results of experience; for it is by multiplied observations collected together that the art is constituted.

87. Some are in the constant practice of finding fault with others, without reaping any other advantages than that of making a vain parade of their knowledge. It appears to me that more wisdom is manifested in finding out useful things, and in perfecting previous observations, than by trying to bring into disrepute, among the vulgar, what ability has produced, and experience confirmed.

88. Those who impugn medicine on the ground that many die under the hands of physicians, in general have as much reason to blame the patient as the physician; but why not impute incurableness to the distemper, rather than want of skill to the physician?

89. Physicians certainly are often in fault; but those that are the least so ought certainly to be the most esteemed.

90. The most skilful and best informed among physicians are sometimes deceived by false analogies.

91. Distempers that are obscure and doubtful are judged of rather conjecturally than by art; but even in these cases the experienced physician has an advantage over one that is not.

92. One physician approves the thing of which another disapproves: it is this which exposes the art to the calumny of the vulgar, who are disposed to consider it altogether vain, and to compare it with the augurs, of whom one says of the same bird, that if it appear on the left it is a good sign, and its appearance on the right is ominous; while another says directly the reverse.

93. In no one instance ought we to speak positively of the success of a medicine, for the minutest circumstance may give rise to variation, and cause a distemper to be protracted and dangerous beyond expectation.

94. The intention of medicine is either to cure disease, or at least to mitigate its virulence; but maladies which are incurable ought not to be undertaken, whether their being incurable depend upon the nature of the sickness, or arise from the destruction of the organ the malady has fallen upon; for it is not in the power of the medicament to reorganise.

95. A physician ought to be frequent in his visits, and exceedingly attentive to every minutia.

96. It is expedient for a physician to have the appearance of health in his countenance; for

the inference is apt to be made, that if he have not health himself he cannot give it to others.

97. A physician ought to be attentive to propriety in his habits, to possess a gravity of demeanor, to be moderate in his actions, and chaste and modest in his conversation with females; he ought not to be envious, unjust, nor a lover of dishonorable gain: he should not be a great talker, but nevertheless ready to give a prompt answer with suavity to every proper question. He should be sober, patient, and ever ready to do his duty; he should be pious without being superstitious, and always conduct himself honorably both in his especial calling and in the general conduct of life.

98. It is not discreditable to a physician, when he feels a doubt about the method of treating a case, to call in the aid of another opinion.

99. As it regards remuneration, a physician ought always to act according to the ability of the patient. On some occasions pecuniary reward ought neither to be asked nor expected; on the other hand the fee may occasionally be given and received in advance, that the patient may with more confidence commit himself to the care of the physician.

100. Those who have considered medicine as having God for its author, have in my mind considered justly. Physicians and philosophers have this in common, that they have the knowledge of the Divinity forcibly impressed on their minds.

101. Such, says Le Clerc, are the principal maxims given by Hippocrates respecting medicine in general, and the duty of its professors. The reader is left to judge for himself on their merits, and physicians may make what use they please of them. It appears from these maxims that there were many physicians in existence at the time when Hippocrates wrote, and but few good ones. It is also evident that consultations were used in his time.

102. Before we quit altogether the part of our history which refers to the 'Coan sage,' it may be right to say a few words on the subject of his writings, and on the question respecting the genuineness or spuriousness of those productions which have been attributed to our author.

103. Under the name of Hippocrates, says Dr. Parr, we have received works of very different value. Those of his predecessors and successors are confounded with his, partly from his having appropriated some of their remarks, in part from the high character he acquired, and from several of his descendants having retained his name. The chief cause, however, of the many spurious works attributed to him, is the avarice of the collectors of Ptolemy, who, when he founded the library of Alexandria, endeavoured to obtain at the most extravagant rates the works of every author of reputation. Every thing under the name of Hippocrates was eagerly received, and it was thought of little importance whether they proceeded from the first, second, or third of that name, so that the reports were not sifted with minute discrimination. To distinguish the real works of Hippocrates has been consequently a problem of no little difficulty. At the expiration of 500 years this task was attempted by Galen, who, with an intimate knowledge of what the successors of Hippocrates had written, possessed a discriminating genius and a critical discernment of the style and manner of the Coan sage, which peculiarly fitted him for the task. Mercurialis, a man of the most extensive erudition; Haller, a physician of vast information, capable of the most incredible labor; and Grumer, possessed of all the indefatigable diligence of his native place, labored in the same field. They have assumed as a principle that Hippocrates was a man of singular abilities, extensive information, consummate candor and modesty. By these tests they have tried every imputed work. Though perhaps the principles might not be readily conceded, yet, as they will certainly point out to our attention the most valuable works, we shall give the result of their labors.

104. The undisputed works of Hippocrates are said to be the first and third books of the Epidemics, two books of the Prænotiones (a different work from the Prænotiones Coacæ, published by Elzevir, in 1660, by Duretus at Paris, and with commentaries by Hollerius at Leyden, which is very certainly spurious), containing the Prognostics and the second book of the Prorrhetica; De Dietâ in Acutis, in opposition to the Cnidian sentences; the Aphorisms; De Aere, Aquis, et Locis; De Naturâ Hominis; De Humoribus purgandis; De Alimento; De Articulis; De Fracturis; De Capitis Vulneribus; De Officinâ Medici; De Locis in Homine. This is nearly the enumeration of Haller; but Galen and Haller seem to have admitted tracts among the Hippocratic works with too great facility. Grumer, who like Haller considered brevity, gravity, and the absence of theoretical reasonings, to be the true test of the genuine writings of Hippocrates, differs in the application. He admits the Oath, but rejects the treatise De Naturâ Hominis, De Locis in Homine, De Humoribus, De Alimento, and De Articulis. Whether the Oath be rejected or admitted is of little importance, since it must be considered rather as an object of curiosity than utility. The first of these rejected works was admitted with hesitation by Galen and Mercurialis, as containing many passages very distant from the manner and doctrines of Hippocrates; but it was retained as containing some facts of importance. The second, though admitted by Galen and Cælius, and though it agrees in general with the practice of Hippocrates, has been suspected on account of some passages of a very different description. Haller only asserts that it may be his work; and Mercurialis, who ascribes it to Hippocrates, thinks that he did not live to complete it.

105. Grumer and Mercurialis reject the tract De Humoribus, but add that it merits attention. It has indeed been commended in every age, and illustrated with commentaries by Galen, Duretus, and Gunzius. The tract on Aliment on the contrary imitates only the terseness of Hippocrates, but betrays the author to be of a later era by the doctrine respecting the arteries and veins. The book on the joints is evidently the work of Hippocrates, or at least of the author of the tract De Fracturis, and universally admitted. It contains also an account of the luxation of the

thigh, which the history of medicine uniformly attributes to Hippocrates, by recording a controversy between him and Ctesias on this subject.

106. Yet even the undisputed works of Hippocrates must be received with some hesitation. The criteria by which they are decided are, we have said, not infallible; for they assume a degree of uniform excellence which perhaps few have possessed. The tract De Aere, Aquis, et Locis, shows the author to have been a European; and various passages, even in the most genuine works, may be adduced to prove that interpolations have crept in. Where then can we draw the line?

107. The style of Hippocrates, says Le Clerc, is very concise, which makes it frequently difficult to comprehend his meaning; to this may be added, that it is grave, and Erotian remarks that there is a similarity between his phrases and those of Homer.

108. His language seems mainly Ionic. Galen observes that the style of Hippocrates inclines somewhat towards the Attic; and he adds that some have considered him as writing in the old Attic.

109. There were several physicians contemporary with him of considerable note in their time, but of such inferior importance in history as scarcely to require notice in the present place. We may mention merely the names of Phæon, Euryphon, Philistion, Ariston, Pythocles, Philetas, Acumenus, and Ægeineus. The sons of Hippocrates were Thessalus and Draco; Polybus was his son-in-law; the first enjoyed the greatest reputation. Ctesian was also a relation of Hippocrates, and contemporary with Xenophon.

110. Diocles was the first in medicine, subsequently to Hippocrates, to make much noise in the world; and on this account he was called by the Athenians the second Hippocrates. A fragment of his is quoted by Galen, which contains a close description of dyspeptic and hypochondriac disorders; his theory of that affection is, that those who are the subjects of it have a superfluous quantity of heat in the veins, which receive the nourishment from the stomach, and that the blood in these veins is consequently thickened, and that thus nourishment is prevented from being distributed through the body, remaining crude upon the stomach and passing the greatest part of it into the lower belly. It is curious to observe in Diocles, an allusion to stomach disorders similar to what is at this very period (1827) the subject of controversy. He states that some conceive that in these affections there is an inflammation at that orifice of the stomach which is connected with the bowels, and that this inflammation occasions a hindrance to the passage of the aliment, and causes the inflation, heat, and other symptoms characterising the disorder. Now, whether in dyspepsia, after it has some time existed, inflammation of the stomach be or be not present is, as we have said, a controverted point among several physicians of the present day. See the several authors who have lately written on dyspepsia, Wilson Philip, Paris, Johnson, and Uwins.

111. Diocles made considerable progress in anatomy considering the impediments of the times in which he lived; but the first great promoters and improvers of this important part of medical and physiological science were Erasistratus and Herophilus.

112. There seems some uncertainty respecting the precise period in which Erasistratus lived. Eusebius places it about the 131st Olympiad, which commenced at the year of the world 3714; but several parts of his history present discrepancies with respect to this alleged time of his birth; for instance, he is stated to have been in great reputation during the time of Seleucus Nicator, who died in the 124th Olympiad. Respecting the part of Greece which gave him birth there seems also to be considerable uncertainty; some have stated it to be Cos, the island in which Hippocrates was born; but it would seem more probable that this supposition has been grounded upon the similarity of the name Cos, and Coa; which last, according to Suidas, was the real birth place of this celebrated man.

113. It seems to be pretty certain that, before the time of Erasistratus and Herophilus, human bodies had not been anatomically examined; and it follows of course that these individuals had opportunities presented them by the permission to investigate human anatomy of a far superior kind to any enjoyed by their predecessors.

114. It is to Erasistratus that we owe the just intimation of a distinct order of vessels in the mesentery as conveyors of chyle; and he with Herophilus were the first to give any thing like a correct account of the brain and nervous system. It has indeed been asserted that Erasistratus recognised two orders of nerves, the one for sensation, the other for motion; and that he described the first as hollow, and taking their origin from the membranes of the brain, while the others originated in the brain itself; but he afterwards spoke of all the nerves originating from the brain itself. He was the first also, according to Galen, to describe, with any thing like accuracy, the membranes which are found about the orifices of the heart, and he speaks of the veins and the arteries as deriving their origin from the heart; but he considers the latter as channels of air, and he supposes respiration to be the process through which air is supplied to the arteries. Some have attributed to him the knowledge of the circulation, but he does not appear to have even been aware of the reason of a double heart. His notion of digestion was that of attrition, as opposed to the concoction and humoral doctrine of Hippocrates; and he differs from Hippocrates in his explanation of the mode in which the kidneys perform the office of separating urine from the blood. He talks moreover of the division of the veins in the liver for the formation of the bile.

115. In his practise Erasistratus was more partial to fasting and abstinence than to blood-letting and purging; and his opinion of disease generally (or rather of febrile disorders) was, that it was occasioned by such a plenitude of the veins as to cause the blood in them to flow into the arteries, and thus to give rise to inflammatory commotion.

116. Respecting the time at which Herophilus lived there seems to be the same uncertainty as

in reference to Erasistratus, some considering him as the contemporary of this last, some making him his predecessor, and some his successor.

117. It was at Alexandria, the capital of Egypt, and under the sanction of the Ptolemies, that both Erasistratus and Herophilus conducted their dissections.

118. Herophilus was the first to point out the optic foramina and nerves, and he speaks still more satisfactorily than Erasistratus respecting the vessels on the mesentery, as being distinct in their œconomy and office from the general venous system. He pointed out also the retina of the eye, and compared that cavity in the brain which goes at present by the name of the fourth ventricle, to the extremity of a writing pen; and described the union of the sinuses, formed by the dura mater; to this day this junction is called the torcular of Herophilus.

119. This author is said to have been the first who described, with any degree of precision, the pulse; and he was so particular in reference to this point, says Pliny, that he contended for the necessity of a knowledge both of geometry and music, in order properly to appreciate the difference of pulsation produced by age and by disorder. Le Clerc, however, contends that this remark of Pliny was founded upon a vulgar error, which attributed this position to Herophilus, because he was the first to make use of the word ρυθμος in application to the pulse. Indeed the precision and science here spoken of seems, as Le Clerc justly remarks, to be inconsistent with the account that has been given, by Galen, of Herophilus, viz. that, in respect to practice, he was half an empiric. Galen actually ranks him among the empirics.

120. Herophilus objected to the prognostics of Hippocrates, and it is surmised that he did so on account of very little attention having been comparatively given by Hippocrates to the pulse. He did not expatiate much upon the curative part of medicine; but it is remarkable that he pointed out particularly palsy of the heart as being a malady which often produced sudden death.

121. It was very shortly after the time of Erasistratus and Herophilus that medicine came to be divided into three parts, the dietetic, the pharmaceutic, and the chirurgical; yet it is observable that, even after the division was acknowledged, the same authors treated of each, the proportion of their attention to one or the other branch being regulated by fancy or by incidental circumstance. The Pharmacopolists of the ancients seem to have been a class of men distinguished from the professors of any of the other branches, and the herbalists were a still different and lower branch.

122. Now also arose the sect of physicians called empirics, who particularly opposed themselves to the anatomical schools introduced by Erasistratus, Herophilus, and their followers. Serapion of Alexandria was the first openly to contend that the science of medicine is and ought to be a mere matter of observation, and that anatomical and physiological knowledge is incapable of affording any real aid in the treatment of disease. Philinus indeed, who was from the island of Cos, is said to be the primary instigator of the empirical creed, and it has even been said that Herophilus was the first to intimate to Philinus the doctrine of experimental observation as opposed to theoretical reasoning.

123. Of Serapion's followers the most famous was Heraclides of Tarentum, who somewhat deviated, it is said, from his predecessors, since he commented on the works of Galen, and dealt in those compositions which seemed to indicate some kind of à priori reasoning as to their separate and combined effects. This inconsistency is charged upon Heraclides by Cælius Aurelianus, who asks how nature or mere accidental observation could instruct men in the composition of medicaments, which seem in the abstract to have so little of correspondence.

124. The question of empiricism and dogmatism is very well discussed by Celsus in his Preliminary Discourse to his Treatise on Medicine, and we recommend its perusal to our young readers, both on account of the fairness and ability with which the investigation is pursued, and the elegant and classical language in which the discussion is clothed.

125. We are now to speak of the introduction of medicine into Rome, or of its transference from Greece to Rome; which, in the infancy of its establishment, was not only indifferent to the reception of the sciences and the fine arts, but was actually jealous of copying the refinements of the Greeks under the apprehension of their eventually leading to effeminacy and weakness. The Romans were said to be nearly 600 years without any medical aid beyond what rude empiricism or blind fanaticism bestowed; and, keeping free from the refinements of their neighbours, they of course did not stand so much in need of the physician's assistance as in after times, when the luxuries of peace took place of the ruggedness of war, and the love of arms ceded to the love of science and art.

126. Rome, says a modern author, formed by the rude tribes of ferocious banditti, wanted for many ages little more than those chirurgical aids which their mode of life rendered indispensable. Epidemic fevers were, however, at times violent and fatal, from the Pontine marshes which were at no great distance from this capital of the world. Yet, for nearly 600 years, they were said to be without medical aid, and their only resources to have apparently been blind empiricism, superstitious charms, or religious ceremonies. Temples seem to have been erected to Febris; and their most destructive enemy, thus raised to the rank of a goddess, was worshipped. In various parts of the city subordinate deities of the same kind were introduced; and no less than three goddesses, Intercidona, Pilumna, and Devirra, were propitiated, by offerings, to confine Sylvanus, who was supposed to be inimical to women in child-bed. In the year 321, ab urbe conditâ, a temple was erected to Apollo for the health and safety of the Roman people; and in 470 Æsculapius, or rather his emblem, a snake, was brought to Rome by a solemn embassy, sent for the purpose to Epidaurus. The snake took refuge in an island in the Tyber, and there the temple of the god was

erected. This fact is of considerable importance in the history of medicine, since it proves that the worship of Æsculapius was continued in Greece at that era; and consequently that traces of record from which as a fountain Hippocrates drew a great part of his observations were still preserved. Some of the votive tablets, hung up in the new temple, are preserved by Gruter, and of a date so late as the age of the Antonines; but these are in Greek, and seem to have owed their origin to the gratitude or superstition of some Greeks who, at that time, resided in the city.

127. It indeed appears singular that while Rome was so little distant from Naples, a Greek city which traced its origin to the Rhodians, among whom Æsculapius was worshipped, should have had no traces of medicine, especially as the Pythagorean philosophy was brought from thence, or from the further provinces styled Magna Græcia, to the Roman kings. The testimony of Pliny, however, is positive; nor is it repelled by Dionysius of Halicarnassus, who remarks in two distinct epidemics, viz. of the years 282 and 400 ab urbe conditâ, that the disease was so violent as to baffle the skill of the physicians; for such would be the language, whatever the medical aid might have been. The stern patriotism of Marcus Cato seems to have prevented the increasing influence of the Grecian physic, and from authority or complaisance Pliny fixed the period of 600 (strictly 535) years during which no physicians were to be found in Rome. It must be obvious that this could not be strictly true; but some resources, either ridiculous or superstitious, must have been sought for when disease occurred. The dietetic system, the virtues of cabbage, adopted from the school of Pythagoras, and the superstitious attachment to the Asclepiadæ, could not have sufficed; but we find little to substitute in their place. The Roman records fail us, and the authority of Cato is supreme. We mean not, in this account, to allude to a law, said to be introduced by Cato, prohibiting the Grecian practice, (for, at the time of the arrival of Archagathus from Greece, he was but fifteen years old); but, to his influence in preventing the increase of the prevailing fashion. The fame of Archagathus quickly faded; for although at first styled Vulnerarius (healer of wounds), he was soon stigmatised by the appellation of Carnifex (executioner). Of the practice of Cato, who wished to supersede the Grecian system, we have hints from Pliny, Plutarch, and his own remaining works. He did not enjoin abstinence, but allowed his patients to eat vegetables. Pliny says cabbage, exclusively, ducks, pigeons, or hares. In fractures and dislocations his remedy was a charm, consisting of hard words without a meaning. The English reader may find some amusement on this subject in the memoirs of Martinus Scriblerus.

128. The bad success of the severer practice of Archagathus soon rendered his successors more gentle in their operations; but some remains of the active Greek surgery continued to prevail, we learn from Plutarch, who informs us that when C. Marius suffered the extirpation of the varices of one leg without a groan, he declined the attempt on the other, saying that the advantages did not compensate for the sufferings.

129. Numerous works have been written to prove that physicians at Rome were slaves, liberti, or foreigners. The opponents of this opinion have been equally voluminous. We must, as usual, give the result of our enquiry without engaging in the controversy. It seems clear that the greater number of practitioners were of the description mentioned, but it is equally certain that many were of a superior character. Archagathus himself was received at first with great ardor, and a house purchased for him; nor on the decline of his credit was he apparently deprived of it. He was also raised to the rank of a Roman citizen, and the Aquilan law declares, that if any physician neglects a slave after any operation he shall be pronounced guilty of a crime. By the same law an action will lie against a physician, who, by the unskilful use of the knife, or of medicine, shall kill a slave, and Ulpian decides that a midwife in the same circumstances shall be pronounced equally guilty. These regulations must relate to free men, and the Aquilan law is confessedly anterior to the age of the Cæsars; for all physicians were by Julius Cæsar raised to the rank of Roman citizens. Varro is also explicit on this subject, when he discusses the question, for what farms it is preferable to have artificers, among whom he reckons medical assistants, occasionally hired, and to what kinds it is better to have slaves attached. In the time of Cato also the Phœnicians had been driven from Sicily by the Romans, and the Macedonians from Greece. The Grecians had therefore recovered a great share of their former liberty. As their language was fashionable, their manners pleasing, their demeanor obliging, perhaps approaching to servility (Juvenal), it is not surprising that they should flock to Rome, nor that they should be favorably received.

130. We are now called upon in the order of time to mention Asclepiades, who was the founder of a new sect of medicine called the Methodic, and who explained all the laws of life and the phenomena of disease upon the principle of the Epicurean philosophy, or rather of the philosophy of Democritus extended and improved by Epicurus. By means of corpuscles and pores, Asclepiades explained every thing. He astonished the people, and was sometimes successful in effecting a cure. He laughed at the ideas of Hippocrates on critical days; he ridiculed his patience in observing nature in order to aid her, or supply her wants; and termed his system a Meditation upon Death.

131. In some consistency with the philosophy of Asclepiades do we find his medical practice. Gestation, friction, and the employment of wine, constituted the three main items of his curative plans, which were all so many means of opening the external and internal pores of the body, and causing the juices and corpuscles to pass from one part to the other freely, and to make their exit liberally.

132. It should seem that the anatomy of Asclepiades was not very correct or extensive, nor was his physiological reasoning entitled to much

commendation. We have spoken of him as the founder of the Methodic sect, but this honor is more strictly due to Themison who succeeded him; and whose system though in some measure harmonizing with the corpuscular philosophy, and regulated by the principles of Asclepiades, was rather, if we may so say, fibrous, than porous; for he divided diseases into those of contracted fibres, those of relaxed fibres, and those of a mixed condition of fibre; in the first he directed evacuants, in the second astringents, and in the third a mixture of both, or rather to meet by the one or the other class of medicaments the most dangerous symptoms.

133. Thessalus, who lived under Nero, about fifty years after Themison, further modified the methodic system especially in its practical bearings; to him has been ascribed the introduction of the metasyncrisial method of treatment, and of causing his patients to abstain from aliment during three whole days, in order to effect a thorough change in constitutional conditions. But it seems that Soranus was most esteemed among the methodical physicians, as having brought the principles of the sect into the greatest degree of practical perfection. This Soranus lived under the emperors Trajan and Adrian. His writings are lost, but their substance is retained by Cælius Aurelianus, who avows that his own works are very little more than a translation of those of Soranus—a translation, for Cælius Aurelianus wrote in Latin. He was indeed an African by birth, according to the most common opinion, but the precise time at which he lived is uncertain.

134. Our limits will not allow us to engage in a lengthened description of the methodic system as it appears in the writings of Cælius Aurelianus: indeed there is in it altogether so much of fanciful and wild, that we should be occupying our time and pages to very little purpose, by transcribing its principles in detail, and we shall content ourselves with the following quotation from Dr. Parr, in reference to the leading doctrine of the methodic school, as, says this author, the cycles of the methodists are often mentioned in medical works, we shall give a short description of the meaning.

135. The cycles were periods supposed to consist of three days each, or combinations of three, and during these the same plans were continued; but at the end of each cycle the exertions were increased, so as at last to arrive at the most active measures. The resumptive cycle consisted of common foods; the metasyncritic of a more acrid and stimulating diet, with frictions, baths, rubefacients, sternutatories, &c. Themison we have said was the principal inventor of this part of the methodic system of medicine. 'The cyclus vomitorius was distinguished into two, as the vomits accompanied the sparer diet of the first, or the more stimulating diet of the second. Each cycle consisted of four diatriti, though sometimes prolonged to sixteen days; the additional diatriton containing four days.'

136. The reader will perceive, in the Asclepiadæan or methodic theory, traces of what we shall afterwards speak of as the humoral doctrine propounded by Boerhaave; and of the system of solidism or fibrous pathology advocated at great length and with much ingenuity by Hoffman, and taught with some modification by the celebrated Cullen.

137. The episynthetic, eclectic, and pneumatic sects of physicians, followed those of the methodic, but their respective peculiarities, as consisting merely in some niceties of bad metaphysics, need not be here dwelt upon; it may suffice to say that the episynthetics affected to reconcile the various discordant opinions of different authors, the eclectics proposed to select from each system the good and practical, and the pneumatics added a governing or spiritual principle to the corporeal or material qualities already recognised; which principle regulated every thing, and occasionally induced disease.

138. Arctæus was the most noted writer among the pneumatic sect of physicians; indeed he is the only author of this sect whose works have descended to modern times complete. It seems uncertain at what precise period Arctæus lived, some have supposed him contemporary with Galen from the circumstance of his never mentioning that author, nor that author him. The principal clue that we have to the discovery of the time in which Arctæus flourished is the dialect of his writing, which is the Ionic, and the circumstance of his being quoted by Paul Eginetus and Aëtius, which proves that he was prior to them. If indeed Arctæus could be proved a contemporary of Galen that would settle the point; for the time in which this last writer lived is as we shall immediately see well known. The writings of Arctæus appear to us to be among the most valuable of ancient records. We may here remark that there is some uncertainty also with respect to the time at which the celebrated Latin writer Celsus lived, some considering him as having been born under the reign of Augustus, others under that of Tiberius, while others again suppose him to have lived so late as the reign of Nero, or even of Trajan. The purity of his style would be almost sufficient to prove him of the Augustan period, and there are other circumstances which favor this presumption. It is curious that Celsus, although one of the best writers on medicine that either ancient or modern times have produced, does not appear to have been himself a medical practitioner. He talks indeed of his observations, but it is supposed that he was merely an observer. Some indeed have gone so far as to imagine that the volumes of Celsus, to which the reader will recollect we have already made allusion, are translations of some Greek author whose name has been lost; for this opinion, however, there does not seem any thing like a foundation; indeed the purity of the style, and the general aspect of the writings of Celsus, would be sufficient guarantees for their originality. We must here repeat our recommendation to the medical student to familiarise himself with the works of this classical author, both on account of the information with which they are pregnant, and the pure Latinity in which they are penned.

139. We come now to speak of the famed Galen, who was born in the second century of the Christian era, under the reign of Severus, and who, for the space of 1500 years, was re-

garded as the oracle of medical science and practice. The birth-place of this celebrated individual was Pergamus a town of Asia Minor; he received the best education of the time under the auspices of a parent, who was himself devoted to philosophy and the belles lettres, and began the study of medicine so early as his seventeenth year, having been it is said directed thereto by a dream of his father.

140. At the time when Galen was born the several sects of physicians, the most conspicuous of which we have just named, were contending for pre-eminence, some practitioners declaring themselves partial to one, some to another, while the eclectics as we have intimated, as indeed their name implies, without attaching themselves to any one code of doctrines, professed to be guided in their philosophy and practice by what of good they found in any of them. To this sect, or rather to these excluders of sects, Galen professed himself attached; but he did not exclude all authority; on the contrary, he avowed his design of restoring the Hippocratic method of considering the objects of medicine, and went so far as to declare himself a disciple and expounder of Hippocrates, who he conceived had been misunderstood or misrepresented, even by those who professed themselves his followers. In commenting however on the works and doctrines of Hippocrates, Galen himself seems to have occasionally given way to the exuberance of a lively imagination, and he seems to have borrowed some of his notions, in respect to animating principles, and regulating essences from the pneumatics.

141. Galen, says Dr. Parr, wrote very diffusely on every part of medicine, but he added only dress and ornament to the system of Hippocrates. In fact minute distinctions, refined speculations, and abstract reasoning, is the whole for which the medical world is indebted to him. They did not lead Galen himself from the path of truth, but they had the most fatal influence on his successors, who speculated when they should have observed, and reasoned when they should have acted. The doctrine of concoction, the most fatal idea which ever occurred, was completely established in the school of Galen.

142. This systematist followed Hippocrates in recognizing three principles in an animal body, viz. the solid parts, the humors, and the spirits; he talked also of four humors, viz. the blood, the phlegm, the bile, and the black bile; the spirits he divided into the natural, the vital, and the animal; the first being nothing else than a subtle vapor rising from the blood, and drawing origin from the liver; these carried to the heart meet with the air we take in by breathing, and become the vital, which themselves are converted into the animal by the action of the brain; these several spirits answer to, and become the instrument of three sorts of faculties—the first or natural having its residence in the liver, and serving for nutrition, growth, and generation; the second, the vital, being situated in the heart, and communicating heat and life to all parts of the body; while the animal faculty is lodged in the brain, which, joined with the rational, distributes feeling and motion through the instrumentality of the nerves, and presides over all the inferior faculties. He supposes three species of actions effected by these three faculties; viz. the natural, the vital, and the animal. He divides the actions of the system moreover into internal and external. The internal actions of the animal faculty being imagination, reasoning, and memory; and the external, the five senses of seeing, hearing, tasting, smelling, feeling, with sentiment, and notion generally. The internal actions of the vital faculty are the violent passions, such as anger, while the external ones are the pulsation of the arteries, and the distribution of blood, and communication of heat and life throughout the frame. The internal actions of the natural faculty are sanguification, digestion and its consequences, and even desire; the external ones are the distribution of the venous blood for nourishment, augmenting, preserving and propagating the species. Besides these general faculties, Galen speaks of other more particular ones which reside in different parts of the body, and which apply to the several demands of these several parts. The stomach, for example, digests by means of its concocting faculty, it attracts nutrition by its attractive faculty, it retains the aliment by its retaining, and discharges it by its expulsive faculty. If we ask what is the primum mobile of all these faculties and functions, Galen, with Hippocrates, replies, it is nature.

143. Health, our author maintains, depends upon the due adjustment of all these faculties, upon the regular distribution of the humors, the proper symmetry of the organic parts, and the harmonious union of the whole; which the reader will be ready to exclaim, is, after all, only to say that health is health; and indeed very little more is predicated by these circuitous modes of expressing absolute circumstance than would be made out by the use of the most common terminology; nor should we have detained the reader with the above sketch, principally borrowed from Le Clerc, of Galenian philosophy, were it not that it is incumbent on us, while professing to give the history of the science, to dwell on the prominent features by which such history is characterised; and did we not feel that the curious, in tracing things to causes, are likely to find an interest in ancient metaphysico-pathology, if we may be allowed the term, from the circumstance that much of ordinary language, in reference to common as well as medical matters, is deducible from the pseudo-philosophy of ancient times. The great error, it will be seen, that pervades the whole of these assumptions, and terms, and inferences, is the localising of presiding powers, the substitution of terms for the exposition of fact, and the confounding of final with efficient cause.

144. When Galen, however, descends from his metaphysics, and discourses on the essence of disease as consisting of plethora and cacochymy his doctrines become more tangible in the way of discussion; and we may shortly state that he imagines these two circumstances, fulness of vessel and depravation of the humors, to be the two great origins of diseased states. In consistency with the Hippocratic doctrine, to which

we have already referred, of the four assumed humors, Galen considers that, beside general plenitude beyond the grade of health, as it regards the blood-vessels, there may exist a bilious, a phlegmatic or pituitous, and a melancholic plethora; but he makes this distinction between the sanguineous and the three other species of plethora: viz. that when either of the latter exists, either separately or conjointly, it mixes with the blood and causes a cachomytous condition of the humors, the morbid condition of the system which thence results being marked by excess of heat, or cold, or dryness, or humidity, or acrimony, or sharpness, or saltness, or sweetness, or any other quality. Even of general plethora he admits of two kinds—the one relative to the vessels, the other to the powers of the system—the former being present when the blood is absolutely superabundant, the other existing when the forces of the body are only equal to the propulsion or management of a certain quantity of blood, and the quantity then becoming, relatively to the powers circulating it, superabundant.

145. On symptoms, diagnosis, and prognosis, Galen treats pretty largely: but we do not find matter under these heads sufficient to detain our readers. Indeed, both as it respects causes and signs and distinctions, there appears to us a good deal of mere verbiage, and certainly no improvement upon his master Hippocrates. On the varieties of pulse he is rather more interesting; but even in this particular we find fancy and conceit occasionally to take the place of observation and truth. We may understand the minuteness, however, with which Galen attended to the circumstance of pulsation, from his having pointed out among others the mouse-tail kind of beat, by which he meant to designate that sort of pulsation which seems as it were to slide through the fingers in the manner of a rat or mouse's tail, and which strikes the different fingers with varied degrees of power.

146. In respect to the practice of Galen we may remark, in the first place, that blood-letting was employed more generally by him than by Hippocrates. He was the first to talk of the precise quantity of blood to be taken in this and that disorder. The principles upon which he directed blood-letting were similar to those of Hippocrates: viz. to lessen fulness, to drive it from parts affected, and to cause revulsion. When the patient was in circumstances to demand bleeding and purging, at the same time, he commenced by the former—which, by the way, may be generally stated not only a good practice, but as an important principle of practice.

147. Anodynes and soporifics were in greater use by Galen than Hippocrates; internal sudorifics were not much employed by him; he occasionally gave specific medicines, or those the modus operandi of which he professed not to understand; but, for the most part, he professed to administer medicaments rather from a principle of philosophical inference than from mere observation, and in this particular, as pointed out by Le Clerc, there was a considerable difference between him and Hippocrates.

148. Galen's anatomical knowledge was of course more extensive and accurate than that of Hippocrates, inasmuch as the actual inspection of human bodies, though still effected with difficulties and obstructions, was certainly occasionally had recourse to, and we have already stated it to be a doubtful point whether Hippocrates had, even in a single instance, enjoyed the opportunity of human dissection. Galen divides the body into four parts—the abdomen, the thorax, the head, and the extremities. The containing parts of the abdomen he describes as the skin covered by the epidermis, or outer skin, the membrane under the skin, and the fat: these are the parts common to this cavity and to other portions of the body, while the parts peculiar or proper to the abdomen are the abdominal muscles, the peritonæum, the epiploon, the stomach, the intestines, the mesentery, the liver, the spleen, the kidneys, the ureters, the urinary bladder, and the generative organs. This division of the intestines is that which obtains even to this day, namely, into duodenum, jejunum, and ilium; cæcum, colon, and rectum. His physiology of assimilation is expressed in the following manner:—The mass of aliment, having arrived in the intestines, is met and received gradually by the meseraic veins, which have the power of attracting the chyle mixed with this mass, in the same manner that the roots of trees draw their nourishment from the earth; they also commence the conversion of this chyle into blood, and carry it to the liver. After the chyle has thus been separated from the alimentary mass the rest of the mass becomes excrement, and is voided by the anus. The liver Galen recognises as the organ principally destined to the formation of blood, and as the origin of all the veins of the body. The spleen is considered as a tissue of vessels like the liver, but being different in the kind of vessels of which it is composed—the latter being principally made up of arteries, while the liver is formed merely of veins: he speaks of the spleen as attracting the black blood from the veins of the liver, thence drawing its nourishment, and transmitting the superfluous portion to the stomach by means of a short vein.

149. We have a description given of the kidneys, and of their blood-vessels coming from the aorta and the vena cava; the ureters are also described as transmitted from the kidneys and terminating in the urinary bladder, which has its sphincter for preventing involuntary discharges. He speaks of the organs of generation in the male and female as being the same, with the exception of difference in size and position; and his theory of generation supposes a mixture and combination of the semen of the female with the semen of the male.

150. In describing the anatomy of the thorax, Galen speaks of the diaphragm, and of a membrane which comes from the parieties of the chest and furnishes the same covering to the lungs and heart that the peritonæum does to the abdominal viscera: he speaks also of a separating membrane between the two cavities of the chest. When describing the heart he speaks of its straight, transverse, and oblique fibres; he describes the pericardium or enveloping membrane of the organ, speaks of the auricles and ventricles of the heart, of its valves, and points out

the difference between the fœtal and adult heart in reference to the distribution of its vessels. He speaks of the lungs as formed of a parenchymatous substance, similar to the liver and the spleen: he mentions the trachea as of cartilaginous formation, points out the laryngeal cartilages, speaks of the situation and office of the epiglottis, describes the thymus gland, but is obscure both in his account of the mode in which respiration is performed and of the vascular connexion of the heart with the lungs.

151. When on the subject of the brain, Galen speaks of the pericranium, of the five sutures, of the dura mater and its sinuses, of a fine or choroid membrane under the dura mater, of the larger and smaller brain, of the ventricles, plexus choroides, pituitary and pineal glands, &c.; and here we have a good deal of wild speculation concerning the use of these several parts of the brain, such as the ventricles receiving and conveying away superfluous moisture, and receiving air from without and preserving the animal spirits in a proper condition. As to the general office of the brain, our author considers it the seat of the understanding, and as giving origin to the nerves. He speaks of the nerves from the cerebellum as principally appropriated to motion, while those from the larger brain are for the sentiments. He speaks of seven pairs of nerves—the optic, the motores oculorum, the lingual, the gustatory, the auditory, the sixth pair immediately following these and giving origin to the recurrents, and the seventh going mainly to the muscles of the tongue. From the spinal marrow he recognises sixty pairs of nerves; the organs of sense are described with some degree of minuteness, more especially the eye; for it is remarkable that in Galen's account of the interior of the ear he is extremely defective: he does not even describe the Eustachian tube, which was discovered and described many years previously to the time in which he lived.

152. Galen speaks of arteries, veins, and nerves as three distinct kinds of vessels; he says the nerves convey sensation and the faculty of motion through all the parts of the body; that the veins and the arteries both convey blood from the centre of the body to its circumference; but that the blood of the veins, which is the grossest, serves to nourish parts, while that of the arteries, being more subtle, is for the purpose of vivifying them.

153. Lastly, we may state in reference to the anatomy of our author, that his description of the bones and muscles is occasionally correct as well as minute; but at times there appears to be reason to suppose that he takes his account from apes and other animals whose external form comes nearest to man, for want of opportunities whence to describe the actual anatomy of the human subject.

154. The epoch of Arabian medicine is so well though briefly given by Cabanis, in his Sketch of the Revolutions of Medical Science, that we shall use the freedom of transcribing the section of that work which refers to this particular.

155. From Galen to the time of the Arabians, says the author just named, medicine appears to have revolved in the circle of the opinions which we have seen successively prevail among the Greeks. Its condition during the continuance of the eastern empire is little worthy of attention. We might perhaps in this interval find some observations worth collecting with respect to the hospitals which were at that time established at Constantinople, and in several other cities of Greece, in Europe and Asia; but this subject has but a remote connexion with that now under consideration.

156. The Alexandrian library, which had been formed by the unremitted care of a long succession of princes friendly to the cause of learning, was burnt during the war between Cæsar and Pompey. A violent insurrection having taken place in the city, Cæsar ordered the ships that were in the harbour to be set on fire. The fire communicated on a sudden to the buildings of the library, and not fewer than 400,000 volumes were consumed by the flames.

157. However this loss was in a short time replaced, at least as far as it could well be. Antony made a present to Cleopatra of the library of Pergamus, which contained 200,000 volumes. This stock was by degrees augmented; the books attracting men of letters, and the men of letters, on the other hand, created an influx of more books. In this manner Alexandria became again the emporium of the sciences and arts.

158. Medicine, in particular, was taught there with much success. Students from all quarters of the globe resorted to it to receive the instructions of the most celebrated masters in the world; and this school, which had been founded in the happiest age of Greece, was still enjoying an undiminished degree of credit when the conquest of Egypt by the Saracens took place.

159. Amron, who commanded the expedition, was desirous to save the library; the answer of Omar is well known. Thus a treasure of incalculable value to the whole human race perished through the barbarous fury of Mussulmans.

160. Yet the proscription was less general with respect to books of medicine, of natural history, and of natural philosophy. Some few escaped destruction either on account of the interest which the most stupid men take in the science which promises them health or an alleviation of their complaints; or, as some writers are of opinion, on account of the idea which generally prevailed in the east, that they would learn from them the art of making gold.

161. The first versions of these books which appeared were in the Syriac language; for the Arabian translations are of a later date. The works of Aristotle and Galen were those for which the Arabians evinced the most enthusiastic admiration. They translated them with the greatest care, and commented on them in different ways and with different views. Their subtle minds were admirably adapted for the Peripatetic system of metaphysics, and for that farrago of abstract propositions which bears down the small number of just and ingenious views it contains. Their literati, who were as fond of pillage as their warriors, appropriated to themselves the ideas that were to be found in works

of little note; and sometimes did not scruple to lay claim to whole books, only taking care to suppress the name of the author. Even their most celebrated writers are not altogether free from this reproach.

162. To the Arabians we are indebted for some important improvements in the art of preparing medicines. They introduced into practice the use of mild cathartics or lenitives: and Rhazes, an Arabian physician, is the first who describes the small-pox. The moderns, no doubt, have far surpassed him in the observation of the different characters it assumes, and of the appearance it exhibits according to the age, the temperament, the state of the body, and the epidemical constitution prevalent at the time when the disease occurs; but it is delineated with much accuracy in his writings; and till the time shall come when the practice of inoculation (simplified as it has been by the beautiful discovery of Jenner) shall have completely effaced it from the catalogue of diseases, Rhazes and some other Arabians who have treated of this disorder (by the way we may remark that Cabanis is not correct in saying that Rhazes was the first to describe the small-pox), will continue to be read with much profit.

163. The works of Hippocrates were translated into Arabic at the same time with those of Aristotle and of Galen. But his simplicity, his precision, his doctrines founded upon experience, that prudent philosophy and rigid method which observes with care the footsteps of nature, were far from exciting the same degree of enthusiasm as the scientific pomp and imposing luxuriancy of the two others; and indeed the Arabian systems of physic have always retained this cast, for in them we look in vain for that genius and that delicacy of discernment which are to the science of medicine what taste is to the polite arts.

164. If we regard merely the absurdity of the enterprise, and the stupid ferocity which gave birth to it, the crusades were nothing more than a cruel and superstitious disorder of barbarous times. But we must at the same time admit that they became very powerful means of weakening and diverting the force of feudal tyranny; and, above all, that they tended to enlarge the intercourse between the ignorant Europeans and the Saracens, who at that time were more enlightened. It also appears that we are indebted to them for the first notion of the municipal system of law. It was at Jerusalem that a class of citizens suddenly emerged from amid the Christian armies, and that their chiefs, by conferring upon them different functions of the magistracy, were enabled by their aid to keep in subjection those bands of turbulent nobles who till then had known no authority.

165. Besides, the better informed part of these nobles, who returned to Europe, brought with them a number of new ideas. The flourishing aspect of the towns and palaces, inhabited and embellished by the Arabian chiefs, and the luxury and conveniency which they exhibited, had naturally inspired them with new desires; and either from this circumstance, or from their connexion with the Genoese and Venetian merchants, the crusaders began first to perceive the value of the arts, and afterwards that of the sciences which elucidate them, or of the literature which enlivens them, which serves them for a guide, and forms, as it were, their necessary accompaniment; and soon diffused a taste for them through the western world.

166. The unfortunate remains of the Alexandrian school, which had escaped the fury or rapacity of the Saracens, were collected by the emperors of the east. While the Arabians endeavoured to promote the advancement of science in Asia and Spain, Greece retained some faint traces of her former splendor. The scenes of so many glorious exploits, of so many feats of genius, and of the industry of its ancient inhabitants, were still before their eyes. The first productions in the most beautiful language that ever was spoken were in the hands of every one; the monuments of which the avarice of the Romans had not been able to deprive them, and those which the luxury of the emperors of Constantinople had raised, at a vast expense, supplied their lively imaginations with ideas that favored the development of all the mental faculties; and, if it had not been for the theological disputes which the folly of princes had kindled, their genius might have shone with a lustre at least as strong as can be expected to emanate among a people that had lost its liberty.

167. It will have been observed that in the above account, taken from Cabanis, the author scarcely alludes to any other physician than Rhazes, who was indeed the great luminary of the Arabians; but, before his time, Isac, Sera pion, and Avenzoar flourished; then afterwards Avicenna wrote very voluminously, and Averrhoes, Alsaravius, and many others, become conspicuous by their works. What the Arabians principally did for medicine was the introduction of several new drugs which the east supplied; but even on this point, as well as in reference to the literature of the art, a great deal was often assumed as novelty which, as above intimated, only consisted in change of nomenclature, or in unacknowledged copies from the Greeks and Romans; nor was the plagiary detected until the time when the Europeans received back, partly by the crusaders and partly by the Saracenic invasion of Spain, that learning which had emigrated and so long been confined to the eastern part of the world. It is a curious fact that the Europeans, at the time to which we are now alluding, actually first became acquainted with the works of Hippocrates and Galen through the medium of Arabic translations.

168. Historians usually at this epoch have introduced to the notice of their readers the particulars of Jewish medicine. The Jews migrating to Spain with the Moors, and still constituting a separate and distinct people, opened schools at Toledo, Grenada, and other parts, and became celebrated as physicians. They became the subjects of persecution; but, in spite of objections raised against them, continued, for a long time, to maintain their ascendancy in public repute, especially in the northern parts of Europe. Scarcely any of their works, however, remain as memorials of the ground of distinction which they so long retained; and they at length became

lost and amalgamated (we now speak of them merely as physicians) with the people among whom they sojourned and associated; and there are no particulars upon which we need at all rest, until the time when chemical medicine came into vogue. What is called alchemy was of Arabian origin. It was in the east that those dreamers first began to speculate and to operate who believed in the transmutation of different metals into gold, and in the existence of a something, could it but be found, which had the power of prolonging the duration of life to an unlimited period. In the researches set on foot to obtain these secrets, and accomplish these objects, many useful facts and principles incidentally unfolded themselves; and as the fanaticism of the crusades was followed by collateral and unlooked for good, so did the folly of the alchemists work out many of nature's secrets, which but for the extraordinary impulse now alluded to might have still remained unknown. But not only did the general fanaticism of the times, but the fanaticism and folly and rudeness of one individual, and that an unlearned man, operate a considerable change upon the character and complexion of medical speculation; and, like Brown in a later period, did Paracelsus at the beginning of the sixteenth century effect a very material revolution in the science and art of healing. This extraordinary man, says Cabanis, whom the solitary practitioner cited by Bordeau calls the greatest fool of physicians and the greatest physician of fools, was unquestionably the prototype of mountebanks—a perfect pattern of pride, madness, and impudence. From the obscurity of the alehouses of Basle he practised upon the credulity of princes, and even of some men who were in other respects very enlightened for their age. Leaving these disgraceful haunts, and attended by a multitude of infatuated adherents, he poured forth a volley of lies, absurdity, and abuse, against his rivals. He proscribed every thing that was not his—he cried, with a frantic voice, 'Away with Greek, Latin, and Arabic!' and he publicly burnt the works the fame of which he was desirous to destroy.

169. Such was Paracelsus, who fancied himself a great man because his name was oftener mentioned in all parts of Europe than that of his contemporaries. Since that time the severest justice has succeeded this infatuation, and there is not a single physician whose opinion is allowed to have any weight who has not perceived the inconsistency of his ideas, and the extravagance of his pretensions. How often have all the odious and ridiculous features in his conduct been exposed and detailed! and yet justice compels us to acknowledge the real services which he rendered to science; the utility of the remedies he first introduced into practice, or which he employed with more boldness and success than his predecessors; and that peculiar sort of sagacity he possessed, which, without meriting the name of real genius, prepares the mind for certain discoveries to which a more cautious mode of procedure never could have led.

170. Paracelsus had perceived the principal errors of the prevailing systems of physic, and had some distant idea of the reforms which they required; and, if his natural disposition had allowed him to do justice to those whom he impudently copied, while he was abusing and reviling them; if he had not been constantly obliged to work upon the passions of the multitude which surrounded him, he no doubt would have been able to promote to a great degree that revolution which was sooner or later to effect the revival of the true science of medicine in Europe.

171. It cannot be questioned that the speculations and dogmata of Paracelsus very considerably influenced the medical doctrines and practice of the times in which he lived; and, although perhaps the most respectable portion of his contemporaries and immediate successors preserved their faith in Hippocratic and Galenic medicine; the chemical mode of reasoning on pathology, and the application of chemistry to medicinal composition, came to be very generally admitted soon after the period at which Paracelsus first announced chimerical novelties, and broached his strange compound of alchemic, astrological, and magical pretensions.

172. Van Helmont is the next of the chemical physicians who demands notice in this place. This celebrated individual had consumed a great part of his youth in studying the works of the alchemists. To him has been ascribed by some the first discovery of factitious airs, and, although there is some error in this unqualified ascription, there cannot be a doubt that much credit is due to him for the mode in which he considered the doctrines of aëriform existence. He was undoubtedly an independent observer, and an original thinker, and we shall here take occasion to make an extract from his writings, which indeed we have already presented to our readers in the article CHEMISTRY; but which, as remarkably illustrative of the workings of an ingenuous and ingenious mind, and as by no means inapplicable to our present purposes, we may here not improperly again introduce.

173. 'In 1594,' says Van Helmont, 'I finished my courses of philosophy, but upon seeing none admitted to examination at Louvain who were not in gown and hood, as though the garment made the man, I was struck with the mockery of taking degrees in arts. I, therefore, thought it more profitable seriously and conscientiously to examine myself, and then I perceived that I really knew nothing, or at least nothing that was worth knowing. I had, in fact, merely learned to talk and to wrangle, and therefore refused the title of M. A., finding that nothing was sacred, nothing true; and I was unwilling to be declared master of the seven arts, when my conscience told me that I knew not one. The Jesuits, who then taught philosophy at Louvain, expounded to me the disquisitions and secrets of magic, but these were empty and unprofitable conceits; and instead of grain, I reaped stubble. In moral philosophy, when I expected to grasp the quintessence of truth, the empty and swollen bubble burst in my hands. I then turned my thoughts to medicine; and, having seriously read Galen and Hippocrates, noted all that seemed certain and incontrovertible; but was dismayed, upon revising my notes,

when I found that the pains I had bestowed, and the years I had spent, were altogether fruitless; but I learned at least the emptiness of books and formal discourses and promises of the schools. I went abroad, and there I found the same sluggishness in study, the same blind obedience to the doctrines of their forefathers, the same deep-rooted ignorance.'

174. It may easily be imagined that an individual, who would think and express his thoughts in this free manner, would not be likely to subscribe to the dicta of established systems; and we find him accordingly breaking through the trammels of the schools, both Hippocratic and even chemical, and proposing dogmata, independent of either. It may be here remarked as a fact worthy observation, that Van Helmont was the first systematically to propound the principle of stomach agency in exciting sympathetic affection to an almost unlimited extent. This sympathetic doctrine has lately been propagated and talked of as something entirely novel; but the merits of the modern pathologists in reference to stomachic influence consist rather in simplification, if we may so say, than in originality; for Van Helmont threw out the idea, but he was not contented to confine himself to the simple fact, but in consistency with the tendency of the times; viz. that of imagining occult and intelligent agencies in the regulation of vital phenomena and morbid incident; he exalted the stomach influence, or rather the influence of the central nerves, into an esssential and governing principle, to which he gave the name of archæus. But we are here tempted again to extract from a modern author in reference to Helmont's views, as the mode in which the doctrine is delineated appears to us so exceedingly just, and to the English reader of the present day so particularly interesting.

175. Van Helmont, says Cabanis, had spent his youth in studying the works of the adepts. Endowed by nature with a glowing imagination, he increased its ardor by his acquaintance with them; and the fire of their furnaces had the effect of completely inflaming his mind. Yet, amid the tarnish of alchemy and superstition by which his ideas are too often obscured, vivid gleams of light are at times observed to appear. It was in pursuing the path of error that he made several fortunate discoveries, and it was in the language of quackery that he announced the sublimest truths.

175*. Van Helmont was one of the most inveterate opponents of the Galenian system, and of the schools which were most in vogue in his time. He indeed allows no opportunity of attacking the latter to escape him; and frequently combats them with great justice and discernment. Nothing could be more unlike his system of physic than that which was then generally taught; but the circumstance of thinking differently from the rest of mankind is not always a sure criterion of thinking rightly.

176. Van Helmont had the merit of being the first who demonstrated the influence which the epigastric organs exert upon the rest of the system. Some obscure hints of this influence were no doubt to be found in the writings of Hippocrates; but the latter appears to have noticed it merely for the purpose of observing the narrow limits within which he supposed it to be confined. No one, after this time, seems to have paid particular attention to the subject, till Van Helmont perceived the potent action of the stomach upon other organs of the body, and that of the digestive power upon their respective functions. He remarked, too, that the diaphragm, which is placed both as a partition and means of communication between the thorax and abdomen, becomes in consequence of its connexion with other parts, and the vicinity of some of the most important viscera, a principal centre of action in the economy of the living system.

177. Numberless facts may be added in support of this opinion. The physicians of the Montpelier school have collected those that are most striking, and have illustrated them in different works with much more method and perspicuity than Van Helmont could have done.

178. Each organ has a sensibility peculiar to itself, although closely connected with, and subordinate to, that of the whole system; particular properties serve to distinguish it from all the other organs; and certain functions are exclusively ascribed to it. Van Helmont supposed that the characteristic distinctions of the different parts of the body depend upon the causes that animate them; and believed that in each organ there resided a principle charged with its government; that a superior principle, to which the author gave the name of archæus, had the superintendence of all the rest; and that from their concurrence and systematic combination the general principle of life results, in the same way as the body itself is formed by the union of all the members. The great archæus is supposed to arise at the superior orifice of the stomach; whence, as it were from his throne, he issues orders to the inferior archæi, according to their different jurisdictions. The latter, though obliged to obey, even the caprices of the former, take care always to add something of their own, either good or bad; and it is in all these operations combined, that the regular actions of the healthy state, and the anomalous appearance of disease consist.

179. The art of medicine then, according to the above theory, consists in the faithful study of the character of the common central principle, and of the nature of the other inferior principles; in knowing when to rouse their industry or suppress their rage; and what are the proper means of governing their passions, or correcting their mistakes. All this, translated into common language, implies, that in animated bodies there exists a general cause of the operations of life; that the different organs, though constantly dependent upon this cause, have, nevertheless, certain modes of being affected and of acting peculiar to themselves, which are the necessary consequence of their peculiar structure; that the object of medicine is to trace the laws by which this cause is governed; to determine the modifications it undergoes in different parts of the system, and in different circumstances, and to ascertain the means of operating, both upon the whole system in general, and upon any organ

in particular, in order to preserve or re-establish the regularity of its functions.

180. This doctrine is confirmed by the observation of nature. It was upon it too that Van Helmont grounded his practical views. Unfortunately he fancied that genius could supply the place of observation; and, rejecting with disdain the facts which had been collected by his predecessors, he boldly adopted plans of treatment that were entirely novel. After the example of Paracelsus, he aimed at the prolongation of human life; he flattered himself that he had discovered the secret, and proclaimed it with the greatest assurance; and, like his predecessor, he shortened his days by those brilliant discoveries which ought to render their authors immortal.

181. We have now arrived at the commencement of the seventeenth century, at which time Dr. William Harvey of London first announced the very important discovery of the blood's circulation; a discovery which furnished a new ground for the whole body of physiological and pathological speculation. Most of Harvey's contemporaries refused to subscribe to the fact, while some endeavoured to deprive the author of the merit of the discovery. We have already had occasion to see how confused and imperfect even Galen's views were with respect to the mode in which the blood makes its passage from the centre to the circumference; he had indeed no idea of a regular circuit. Servetus, the noted object of Calvin's persecution, was a Spanish physician, and in a medico-theological work he mentioned that the blood finds its way from the pulmonary artery into the veins; but, even allowing that such intimation laid claim to a discovery, it is at best but a discovery of the pulmonary circulation, and cannot possibly be considered as any thing like an anticipation of the great Harveyan doctrine. Servetus indeed with Galen limits the blood to the liver and veins generally, and, confusedly and inconsistently with his other assumptions, imagines the heart and arteries to be the instruments of aerial or spiritual transmission. Columbus also, to whom the discovery of the circulation has been attributed by some, although he seemed to have an idea of the pulmonary circulation, and although he described the structure and office of the valves of the heart, fell in with the Galenic notion of venous origin; and Cæsalpinus, who very shortly followed him, still manifests confusion when he mentions the mode in which the system is supplied with alimentary blood; in a word, the actual transmission from, and return to, the heart of the mass of circulating blood, was first unequivocally detailed and explained by Dr. Harvey; and it might have been anticipated that from this time forward medical doctrine and medical practice, commencing as it were from a new starting point, would have regularly, if not rapidly, proceeded on to a state of comparative perfection. But no; this new instrument of truth was destined to become, in the hands of men prone to error, a new excitation of fanciful and futile hypotheses and systems. As the Paracelsian chemists, and the disciples of Helmont, had derided the Galenic faith, so the chemical æra now in its turn gave way before the fury and fanaticism of a mathematical mania, which by axioms, postulata, and corollaries attempted to explain the functions of life and the features of disease. Nothing now was thought of but hydraulic motion, and mathematical calculation of forces; the circulation of the blood, and the laws regulating it, constituted the whole compass of physiological and pathological principia; and medicine was from first to last correcting circulatory impulse, or changing the circumstances and condition of the blood. How futile and far from truth some of the positions and inferences of the mathematical physicians were, may be inferred from the vast difference of premises and deduction which different theorists broached in reference to the same particulars: while, for example, one estimated the force of the heart at a few ounces, another calculated it to be many pounds. And, with regard to the practical inferences which resulted from these mathematical dogmata, an author, from whom we have already largely borrowed, expresses himself in the following terms:—The new light which was thrown upon the animal economy, by this important discovery (the circulation), served only we may affirm to redouble the rage of systems. Nothing else was thought of but to cause the blood to circulate more freely, to destroy its viscosity, to draw off from the body that which was supposed to be corrupted, to purify it, correct it, and renew it, and to preserve the blood vessels in a relaxed and pervious state. Hence those torrents of aqueous and diluent drinks, with which Bontikoe and his adherents inundated their patients. Hence that sanguinary fury which the partisans of Botalli thought themselves entitled to exercise in their treatment of all sorts of diseases; a fury which, though so often damped in some measure by systematic murders, has ceased only for intervals, and still, from time to time, re-appears in the schools.

182. Thus one of the most beautiful discoveries of modern medicine, far from elucidating the practice of the art, as there was every reason to expect, only had the effect of misleading weak imaginations, dazzled by its splendor; and it may still be doubted whether its application to the knowledge and cure of internal diseases has been of any real use. In surgical cases, even where its assistance is generally regarded as indispensable, might not observation almost always supply its place? and must we not limit its importance to the elucidation of a point in anatomy and physiology, very curious no doubt in itself, but which, if it did not indirectly affect many other interesting questions relative to the animal economy, would perhaps have contributed very little to our knowledge of its true laws?

183. However, under this point of view alone, the discovery of the circulation has been productive of advantages by which the practice of medicine has eventually profited; and the glory of its authors can be contested only by the most ridiculous envy, or the most inconsiderate attachment to paradox.

184. The chemical theories of acids and alkalies, which were applied to the fluids of the living body; the pure mathematical theories, by means of which men, who were in general of in-

[illegible] and geometers, [illegible] functions of the dif[illegible], the hydraulic theories [illegible] which served as the foundation [illegible] calculations with re[illegible] of the blood and other [illegible] the mechanical views that [illegible] the laws of motion, [illegible] the phenomena of life, or [illegible] which may be derived [illegible] with them in the illustra[illegible]; all began to attract [illegible], when there appeared a [illegible] who was destined to effect a real [illegible] of medicine.

[illegible] alluded to is the celebrated [illegible] before we engage in a slight [illegible] the merits of this indi[illegible] the peculiarities of his theory, we are [illegible] to introduce to our readers' notice [illegible] physician, who, by one leading prac[illegible], and by the general substitution of [illegible], and untrammelled observation, for [illegible], and hypothetic inference, did [illegible] the science of medicine than had been [illegible] scholastic and theoretic principles for [illegible] will have been seen that even Hippo[crates] himself (who has justly been called the [illegible] of nature, in contrast with others who [illegible] demand that nature should accommo[date] [illegible] to their postulata, and not them to [illegible], it will have been observed, we say, that [illegible] in the writings of Hippocrates the notion [illegible] concoction of humors, previous to their ex[pulsion], is defended as a principle of practical [illegible]. By others this principle was car[ried] still further into practice; and, at the time [when] Sydenham made his appearance in the [world] of medicine, heating alexipharmic ma[terials] were forced down the throats of the sick, [under] the assumption now referred to, without [measure], and without mercy—without mercy, [we say]; for the sufferings, and manifestations of [sufferings], of the sick, were disregarded among the clamorous calls of a prevailing system thus founded in misconception, and acted upon in cruelty.

185. Sydenham at once saw the error of this plan of treatment, and boldly proposed and carried into effect a reformation, which, as we have above intimated, was attended with practical good of the most unequivocal and extensive kind. But we are here again tempted to make a long extract from an author upon whom we have already made large demands, and whom we always find much satisfaction in quoting; in the present instance the testimony of an enlightened foreigner, given with so much propriety of feeling and freedom from all sort of prejudice, upon the merits of our own countrymen, will be received with the approbation due to its value.

186. When Sydenham (says Cabanis), appeared in England, the science of physic still retained its scholastic form. The progress of the other branches of knowledge had hitherto exerted only a prejudicial influence upon it; and the general spirit of observation was almost entirely unknown. Sydenham, after a short course of study, assisted by a little reading, but guided chiefly by the impulse of a happy genius, undertook to bring back the practice of the art to the path of experience. With the prevailing theories of the time he was but imperfectly acquainted; but this circumstance was perhaps more favorable to his labors, as it could never be embarrassing to his self-love, and as he would find less difficulty in following the footsteps of nature. Among the number of his friends was the illustrious Locke, to whom we are indebted, if not for the first principles of a philosophical method of enquiry, at least for the first demonstration of the fundamental truths on which they are founded. The friendship of such a man sufficiently indicates the disposition of mind of the person who cultivates it, and serves, as it were, for its standard comparison. We can therefore scarcely doubt that the counsels of the philosopher must have greatly contributed to the success of the physician, who indeed acknowledges it himself with candor.

187. Sydenham attacked with the irresistible arms of experience several destructive prejudices which at that time prevailed. The chemists, for instance, had introduced into medicine the indiscriminate use of cordials and of ardent or volatile spirits. In acute diseases, in particular, the abuse of these remedies was very great. Sydenham proved that, in such cases, they were almost always injurious, but especially at the commencement of the disorder. The small pox and other acute cutaneous eruptions were treated by sudorifics alone. Sydenham demonstrated that this mode of practice had been more fatal to mankind than a long succession of destructive wars. His Treatise on the Gout has been generally regarded as a master-piece of description; it is indeed the most perfect account of this disease which we possess; not that this malady always presents itself in the manner in which it is described, but because we can conceive nothing more accurate or ingenious than the plan of observation which he there lays down.

188. Hippocrates, in his Epidemics, had sketched the outlines of a system of physic as extensive as it was original. During several ages his ideas had remained in a manner dormant. Baillou, a Parisian professor, in the sixteenth century, appropriated them to himself, and extended them: not indeed as a man of genius; for he was not such, but at least as an attentive observer, and skilful practitioner. He was even led to consider them in several new points of view.

189. Sydenham, without having any knowledge of Baillou, perhaps even without having read Hippocrates, was led into the same path by observation alone. He pursued it with still greater success; and in this his chief glory consists. It is only since his time that we have become thoroughly acquainted with those general variations to which the character of epidemic diseases are liable; with the relations they bear to each other; and their connexion with the different apparent changes of the atmosphere, or their independence of these changes, which is often very apparent; with the influence they exert on sporadic or local disorders; and, lastly, with the manner in which their succession is

regulated, although the order of it, we must confess, has not yet been subjected to any determinate rules, upon which we can entirely rely.

190. The practice of Sydenham effected a real revolution in physic. It was the triumph, not of a transcendant genius, who reforms every thing by bold and general views, but that of an observer, who investigates with sagacity, who conducts his researches with skill, and who is always guided by a sure method. The theories of Sydenham were, it must be acknowledged, contracted, or even erroneous; and beyond the sphere of his experience, in which his natural penetration supplied the place of all other talents, his ideas were in general very limited; but no physician ever exerted so beneficial an influence on that branch of the art to which all the others are subservient—on its practical application; and, in this respect, no one was ever more deserving the title of the restorer of true medical science.

191. Boerhaave, whose name we introduced immediately preceding the above extract from Cabanis, was in one sense the opposite to Sydenham. He, like some others, was a philosopher before he was a physician; and the medical system which he broached and acted upon, so far from being merely the result of simple observation and strong sense, as in the case of Sydenham, was drawn from the principles of chemical and physical science into which he had been early initiated.

192. This celebrated individual, and amiable man, was in one particular like the eclectics of old: he aimed at incorporating with his own particular views, the best portions of the medical philosophy which had preceded him. We have no reason, says a modern writer, to think that he expected to be the founder of a sect; yet he proceeded with the caution of a veteran, and culled from each the flower which was to adorn his own parterre. Though Paracelsus had burnt the writings of Hippocrates and Galen in solemn state, yet they were not forgotten; and the wise observations of the Grecian sages formed the ground-work of his system. The Galenic doctrine of humors he assimilated with wonderful address to his chemical doctrines, and gave them a specific character, founded on their chemical relations. The mechanical philosophy, then attracting universal attention, added to the fabric; the vessels were cones or cylinders; the fluids, consisting of various particles adapted only to given apertures, were at times forcibly impelled and impacted in vessels to which they were not fitted, and consequently produced numerous complaints.

193. The above extract from Dr. Parr may be taken as an outline of the Boerhaavian system of medicine, which turned upon the lentor and acrimony of the fluids, and upon the impelling and correcting power of therapeutic agents; supposing too that the solid portions of the living system were so susceptible of chemical and mechanical changes, that the laws of life and the phenomena of disease were referrible to alterations of form, or variety of constitution, in all his positions and inferences, forgetting or overlooking, as his predecessors had also done, that the reasoning, even when correct, that applies to formative change or impelling powers has qualifications and limits which demand careful recognition when it comes to be applied to organised being.

194. In a manner to remedy this defect of the Boerhaavian doctrine, the doctrine of Stahl, modified by Hoffman, came to be promulgated. In the opinion of Hoffman the actions of the living solid were to be looked upon as the main springs of disordered being; that to the affection of the solidum vivens the deranged conditions of the fluids are subordinate; and that to 'the exertions of the vital power in changing the direction and balance of the circulation,' are we to look for an explanation of all the varieties which disease assumes. Stahl adopted the same principle, but he carried his notion of living agency to the pitch of a presiding intelligence guarding against the invasion of disease. 'He acknowledged, with Van Helmont, a ruling power, guarding the constitution and repairing every defect that might occur; but with this superintendence he considered the human system as a living and an irritable machine, susceptible of various and irregular motions, and consequently of topical congestions.' To these irregular motions, originating as it was supposed, in the living fibre, the term spasm came to be applied; and it is to the solidists, as they have been termed, in opposition to the Boerhaavian tenets, that we are to trace the introduction of the word spasm, as illustrative of disordered condition of the animate fibre, while the phraseology which talks of humor and acrimony is the phraseology borrowed from the doctrines of Boerhaave.

195. Dr. Cullen tells us, in the preface to his first lines of physic, that, when he was appointed professor in the Edinburgh University, he found the humoral pathology in full force; in the development of his own opinion he, however, expressed himself more partial to the views taken by the solidists; and we find in Cullen the term and notion of spasm to form a conspicuous feature in his pathological code; the reaction to overcome this spasm constituting the perturbation of disease, and yet, being regulated by a vis medicatrix, which is the ενορμων of Hippocrates, the archæus of Helmont, and the ruling power or rational principle of Stahl.

196. The theory of Cullen, which is in fact a modification of the Stahlian and Hoffmanic doctrines of medicine, came to be received and taught in the Edinburgh school; and the terminology of the times was spasm and reaction in place of lentor and acrimony; in other language we might say the principles of the solidists superseded in a very considerable measure the assumptions and inferences of the Boerhaavian pathology. The works of Gaubius, of Haller, and of Whytt; the first, a celebrated pupil of Boerhaave, who considerably modified the doctrines of his master; the second an author of notoriety, who published on the irritability of the fibre, and of whom we shall have more to say under the head of PHYSIOLOGY; and the last a writer on nervous sympathies; all contributed towards a modification of the Boerhaavian and Stahlian theories: and things were in this state

when Brown, in some measure like a second Paracelsus, started into notice—we say like a second Paracelsus, because he boldly and at once avowed his unqualified dissent from all that had gone before him, and not only opposed but ridiculed and contemned all the attempts which hitherto had been made to combine into one systematic whole the principles of life and the causes of disease.

197. Deviation from the state of health, in which the morbid state consists, is not, says Brown, either repletion or inanition, or changes in the quantities of the fluids, whether of an alkaline or of an acid nature; or the introduction of foreign matters into the system; or a change of figure in the extreme particles; or a disproportion in the distribution of the blood; or an increase or decrease of the powers of the heart and vessels as regulating the circulation; or a rational principle governing the actions of the body; or an alteration in the extreme particles as being of too large or too small a size; or an alteration of the pores as being too narrow or too capacious; or a constriction of the superficial vessels from cold; or a spasm of these vessels producing a reaction, as it is called, of the heart and interior vessels; or any thing that any person has yet thought of respecting the cause and nature of the morbid state. On the contrary, health and disease are the same state, depending on the same cause, that is excitement, varying only in degree; and the powers producing both are the same, sometimes acting with a proper degree of force, at other times either with too much or too little: the whole and sole province of a physician is not to look for morbid states and remedies which have no existence, but to consider the deviation of excitement from the healthy standard, in order to remove it by proper means.

198. It will be readily seen, says a modern writer, that this subordination of every thing in the living economy to the leading and master-principle of excitement, constitutes the essence of Brunonian pathology and practice. A subordination that may be illustrated by adducing one or two examples. Suppose an individual to be affected with the disorder called diabetes, which disorder is constituted mainly of an altered quantity and condition of the urinary secretion; at least, that is one of its most prominent characteristics. The philosophy of Brown would teach us that the general systematic derangement, by which the malady is constituted, is the only matter of consequence to attend to; and could we but bring the excitement, that is the healthy actions of the system, to a proper balance and bearing, every thing else would fall by consequence into regularity and order; the functions of the kidneys would be restored to their wonted integrity, and health would take place of disease.

199. Again, suppose that a man falls down in an apoplectic fit, he dies, and you examine the condition of the brain; whether it is or is not laden with an undue quantity of blood and serum; whether some of the blood-vessels of the organ have or have not given way; the main circumstance to be regarded, in appreciating the nature of the affection, is the extent to which the excitement has been implicated; and the only effectual way of warding off attacks of apoplexy or even of remedying them when they are remediable, is not to set about emptying the blood-vessels, which is a debilitating process, and calculated to be destructive of its own design; but to aid the sinking and restore the lost excitement. To cure disorder, upon the Boerhaavian hypothesis, is to correct the acrimony of the fluids, or diminish their lentor, or to open the pores of the body for their exit. The Cullenian would say, Take off spasm from extreme vessels and excite, repress, or regulate reaction; while Brown's disciples would say, Adjust and adapt the excitability to the powers which excite, and you need not trouble yourself about any thing further.

200. This Brunonian doctrine of excitability was modified and complicated by Dr. Darwin into four distinct divisions. All diseases, says this last systematist, originate in the exuberance, deficiency, or retrograde action of the faculties of the sensorium as their proximate cause, and consist in the disordered motions of the fibres of the body, as the proximate effect of the exertions of those disordered faculties.

201. The sensorium possesses four distinct powers or faculties, which are occasionally exerted, and produce all the motions of the fibrous part of the body. These are the faculties of producing fibrous motions in consequence of irritation, which is excited by external bodies; in consequence of sensation which is excited by pleasure or pain; in consequence of volition, which is excited by desire or exertion; and in consequence of association, which is excited by other fibrous motions. We are hence supplied with four natural classes of diseases, derived from their proximate causes, which we shall term those of irritation, those of sensation, those of volition, and those of association.

202. Darwin's propositions and principia may be considered the last to have been organised into a body of systematic doctrine. Since his time attempts to generalize have been of rather a different cast: thus, instead of uniting physic with metaphysic and aiming to reduce vital causation, and deranged action to one leading and generally applicable law, in the same manner that gravitation is applied to the phenomena exhibited by inanimate matter; and which attempts, by the way, have all proved nugatory; the endeavours of recent systematists have rather been those of localising disease, or of aiming to prove that affections of this or that part, or primary derangement of one or another organ, are the main springs of general perturbation. Some of these theorists, evincing a disposition to place this fons et origo malorum in the liver, some in the brain, some in the stomach, and some in the fine membrane which secretes mucus and lines internal cavities. And it is a curious fact that the organic theories, if so they may be termed, have seemed to originate in the downfal of the Brunonian assumption of mere general excitement; or rather when it was perceived, as it soon must have been perceived, that these principles were too comprehensive and sweeping to be applied to the complicated organisation of the

living body, the contrary principles, from the tendency there is in the human mind to reacting extremes, came into play; and, as it has been expressed, from no organ it came to be all organ. And there has been another manifestation of opposing principle in the more recent fashion of placing every thing connected with morbid being to the account of the blood-vessels, which is in contradistinction to the nervous theories of the solidists and animists who have just passed by; so it will be seen that the spirit of system, though curbed and crippled by the good sense of modern times, has not yet totally disappeared. Indeed, theory, after all, must more or less influence practice, even among the least disposed to abstract reasoning. 'With some,' says a writer whom we have already quoted, 'the notion of theory, as applied to the art of healing diseases, is considered to be altogether nugatory; and it must be admitted that much of medical doctrine and dicta has prevailed at different times without proving materially influential upon practical indications. I am ready, moreover, to admit, that a large proportion of therapeutic endeavour is conducted, more especially in the present day, under the guidance of an empirical good sense, without reference to the institutes of determined systematists; but still it will be found that the most decided oppositionist to partial views, and particular creeds, is in a greater or less degree influenced in his feelings, and directed in his habits, by the prevailing theories of the times. No one surely will deny that up to the present moment many sensible and unsystematic practitioners are pushing at the liver, and prescribing blue pill, or correcting the chylopoietics, or emptying the blood vessels, or battling at congestion, or thinking about morbid condition of mucous membranes; who, had they been living in the days of Boerhaave, of Hoffman, or of Cullen, would have been acting under the notion of deobstruent agency; have been busily employed in attempts to restore the balance of nervous and fibrous excitation, or in finding out the best methods of resolving spasm, and regulating reaction.' The writer might have added that, had his supposed practitioner been the practitioner of times preceding Sydenham, he might have been waiting for the coction of humors, and permitting the disorder to proceed without interruption till this imaginary process was complete; or he would have been adding irritation to too much already present, under the idea of forcibly expelling humors. Another difference in these cases would not, as it is remarked, be merely in terminology; the medicaments and actual modes of management would also differ; so that it is of some consequence, to say the least, for us to look well to the correctness of propounded principia before we permit them to become either in whole or part 'parcel of the mind.' And it further behoves us to look well towards the correction of another, but opposite tendency, viz. that which refuses to receive any of the good of system, inasmuch as it is mixed with evil. To think is to systematise, and a process of thought must ever precede all acts that are not instinctive or involuntary. 'It is impossible to observe the various appearances in nature without remarking certain circumstances in which they agree; to remark these circumstances is to arrange the similar appearances. It is thus impossible not to systematise; and hence the question should be, not whether systems be useful, but to what extent, and in what mode they can be most usefully formed.'

203. There ought of course to be as little as possible assumed; or rather, the assumption having been once made, its legitimacy ought not to be blindly and obstinately maintained; but, on the contrary, it should be tried by the severest tests of affiliation. Thus, if we find post mortem appearances subsequent to a certain series of symptoms, we may register or arrange the two circumstances under one head of cause and effect; and pleasure may arise from having detected a connexion which has escaped the sagacity of others; but to this supposed discovery such a partiality must not be conceived, as that its cause must be defended against subsequent development of truth. And it is precisely from this point whence all the errors of systematists commence and proceed. When we talk of congested veins, inflamed arteries, disordered tissues, chylopoietic disturbances, and hepatic derangements, as influencing the whole series of organic movements; is not one link only in the chain of causation open to our perception, while the remainder are among the invisible or dimly seen? Are we not apt to overlook the impelling, in our eagerness to grasp at the impelled? In other words, do not we seize hold of one or two striking facts in morbid manifestation, and, hurrying away with them to our closets, mould them into a mass, and eventually throw them out upon the world as presents from nature, whereas they are in reality half the products of our own manufacturing ingenuity? Thus, for a time, the most daring and novel become the most accredited propositions; but as soon as their charm of novelty is gone by, and their propounders are laid in the silent grave, the adventitious separates itself from the real, and the dross is discovered to bear an immeasurably large proportion to the intrinsic of the doctrine.

204. Brown would have effected an abundance of good had he been content to have ridiculed the metaphysical abstractions, or physical absurdities, of preceding systematists; but his failure consisted in attempting another abstraction, in lieu of those he had hurled to the dust; and an abstraction which was still more mischievous in its bearings than those that had gone before; inasmuch as that part of it which was illegitimate and bad was more positively and practically so than its predecessors It is indeed frightful to contemplate the evil that must have resulted from the determined application of his sweeping dogma, which it is surprising was not sooner brought to the ad absurdum test of trial as to its rectitude. But even in this system, degraded as it at present is, a great deal of actual good may be discerned; and a great deal, moreover, of the indirect and direct occasion of those theories that are at present the order of the day.

205. To this circumstance we have already adverted; and we have in some measure anticipated, in the latter clauses of this historical sketch, the second head proposed for disquisition,

we have already referred, of the four assumed humors, Galen considers that, beside general plenitude beyond the grade of health, as it regards the blood-vessels, there may exist a bilious, a phlegmatic or pituitous, and a melancholic plethora; but he makes this distinction between the sanguineous and the three other species of plethora: viz. that when either of the latter exists, either separately or conjointly, it mixes with the blood and causes a cachomytous condition of the humors, the morbid condition of the system which thence results being marked by excess of heat, or cold, or dryness, or humidity, or acrimony, or sharpness, or saltness, or sweetness, or any other quality. Even of general plethora he admits of two kinds—the one relative to the vessels, the other to the powers of the system—the former being present when the blood is absolutely superabundant, the other existing when the forces of the body are only equal to the propulsion or management of a certain quantity of blood, and the quantity then becoming, relatively to the powers circulating it, superabundant.

145. On symptoms, diagnosis, and prognosis, Galen treats pretty largely: but we do not find matter under these heads sufficient to detain our readers. Indeed, both as it respects causes and signs and distinctions, there appears to us a good deal of mere verbiage, and certainly no improvement upon his master Hippocrates. On the varieties of pulse he is rather more interesting; but even in this particular we find fancy and conceit occasionally to take the place of observation and truth. We may understand the minuteness, however, with which Galen attended to the circumstance of pulsation, from his having pointed out among others the mouse-tail kind of beat, by which he meant to designate that sort of pulsation which seems as it were to slide through the fingers in the manner of a rat or mouse's tail, and which strikes the different fingers with varied degrees of power.

146. In respect to the practice of Galen we may remark, in the first place, that blood-letting was employed more generally by him than by Hippocrates. He was the first to talk of the precise quantity of blood to be taken in this and that disorder. The principles upon which he directed blood-letting were similar to those of Hippocrates: viz. to lessen fulness, to drive it from parts affected, and to cause revulsion. When the patient was in circumstances to demand bleeding and purging, at the same time, he commenced by the former—which, by the way, may be generally stated not only a good practice, but as an important principle of practice.

147. Anodynes and soporifics were in greater use by Galen than Hippocrates; internal sudorifics were not much employed by him; he occasionally gave specific medicines, or those the modus operandi of which he professed not to understand; but, for the most part, he professed to administer medicaments rather from a principle of philosophical inference than from mere observation, and in this particular, as pointed out by Le Clerc, there was a considerable difference between him and Hippocrates.

148. Galen's anatomical knowledge was of course more extensive and accurate than that of Hippocrates, inasmuch as the actual inspection of human bodies, though still effected with difficulties and obstructions, was certainly occasionally had recourse to, and we have already stated it to be a doubtful point whether Hippocrates had, even in a single instance, enjoyed the opportunity of human dissection. Galen divides the body into four parts—the abdomen, the thorax, the head, and the extremities. The containing parts of the abdomen he describes as the skin covered by the epidermis, or outer skin, the membrane under the skin, and the fat: these are the parts common to this cavity and to other portions of the body, while the parts peculiar or proper to the abdomen are the abdominal muscles, the peritonæum, the epiploon, the stomach, the intestines, the mesentery, the liver, the spleen, the kidneys, the ureters, the urinary bladder, and the generative organs. This division of the intestines is that which obtains even to this day, namely, into duodenum, jejunum, and ilium; cæcum, colon, and rectum. His physiology of assimilation is expressed in the following manner:—The mass of aliment, having arrived in the intestines, is met and received gradually by the meseraic veins, which have the power of attracting the chyle mixed with this mass, in the same manner that the roots of trees draw their nourishment from the earth; they also commence the conversion of this chyle into blood, and carry it to the liver. After the chyle has thus been separated from the alimentary mass the rest of the mass becomes excrement, and is voided by the anus. The liver Galen recognises as the organ principally destined to the formation of blood, and as the origin of all the veins of the body. The spleen is considered as a tissue of vessels like the liver, but being different in the kind of vessels of which it is composed—the latter being principally made up of arteries, while the liver is formed merely of veins: he speaks of the spleen as attracting the black blood from the veins of the liver, thence drawing its nourishment, and transmitting the superfluous portion to the stomach by means of a short vein.

149. We have a description given of the kidneys, and of their blood-vessels coming from the aorta and the vena cava; the ureters are also described as transmitted from the kidneys and terminating in the urinary bladder, which has its sphincter for preventing involuntary discharges. He speaks of the organs of generation in the male and female as being the same, with the exception of difference in size and position; and his theory of generation supposes a mixture and combination of the semen of the female with the semen of the male.

150. In describing the anatomy of the thorax, Galen speaks of the diaphragm, and of a membrane which comes from the parieties of the chest and furnishes the same covering to the lungs and heart that the peritonæum does to the abdominal viscera: he speaks also of a separating membrane between the two cavities of the chest. When describing the heart he speaks of its straight, transverse, and oblique fibres; he describes the pericardium or enveloping membrane of the organ, speaks of the auricles and ventricles of the heart, of its valves, and points out

the difference between the fœtal and adult heart in reference to the distribution of its vessels. He speaks of the lungs as formed of a parenchymatous substance, similar to the liver and the spleen: he mentions the trachea as of cartilaginous formation, points out the laryngeal cartilages, speaks of the situation and office of the epiglottis, describes the thymus gland, but is obscure both in his account of the mode in which respiration is performed and of the vascular connexion of the heart with the lungs.

151. When on the subject of the brain, Galen speaks of the pericranium, of the five sutures, of the dura mater and its sinuses, of a fine or choroid membrane under the dura mater, of the larger and smaller brain, of the ventricles, plexus choroides, pituitary and pineal glands, &c.; and here we have a good deal of wild speculation concerning the use of these several parts of the brain, such as the ventricles receiving and conveying away superfluous moisture, and receiving air from without and preserving the animal spirits in a proper condition. As to the general office of the brain, our author considers it the seat of the understanding, and as giving origin to the nerves. He speaks of the nerves from the cerebellum as principally appropriated to motion, while those from the larger brain are for the sentiments. He speaks of seven pairs of nerves—the optic, the motores oculorum, the lingual, the gustatory, the auditory, the sixth pair immediately following these and giving origin to the recurrents, and the seventh going mainly to the muscles of the tongue. From the spinal marrow he recognises sixty pairs of nerves; the organs of sense are described with some degree of minuteness, more especially the eye; for it is remarkable that in Galen's account of the interior of the ear he is extremely defective: he does not even describe the Eustachian tube, which was discovered and described many years previously to the time in which he lived.

152. Galen speaks of arteries, veins, and nerves as three distinct kinds of vessels; he says the nerves convey sensation and the faculty of motion through all the parts of the body; that the veins and the arteries both convey blood from the centre of the body to its circumference; but that the blood of the veins, which is the grossest, serves to nourish parts, while that of the arteries, being more subtle, is for the purpose of vivifying them.

153. Lastly, we may state in reference to the anatomy of our author, that his description of the bones and muscles is occasionally correct as well as minute; but at times there appears to be reason to suppose that he takes his account from apes and other animals whose external form comes nearest to man, for want of opportunities whence to describe the actual anatomy of the human subject.

154. The epoch of Arabian medicine is so well though briefly given by Cabanis, in his Sketch of the Revolutions of Medical Science, that we shall use the freedom of transcribing the section of that work which refers to this particular.

155. From Galen to the time of the Arabians, says the author just named, medicine appears to have revolved in the circle of the opinions which we have seen successively prevail among the Greeks. Its condition during the continuance of the eastern empire is little worthy of attention. We might perhaps in this interval find some observations worth collecting with respect to the hospitals which were at that time established at Constantinople, and in several other cities of Greece, in Europe and Asia; but this subject has but a remote connexion with that now under consideration.

156. The Alexandrian library, which had been formed by the unremitted care of a long succession of princes friendly to the cause of learning, was burnt during the war between Cæsar and Pompey. A violent insurrection having taken place in the city, Cæsar ordered the ships that were in the harbour to be set on fire. The fire communicated on a sudden to the buildings of the library, and not fewer than 400,000 volumes were consumed by the flames.

157. However this loss was in a short time replaced, at least as far as it could well be. Antony made a present to Cleopatra of the library of Pergamus, which contained 200,000 volumes. This stock was by degrees augmented; the books attracting men of letters, and the men of letters, on the other hand, created an influx of more books. In this manner Alexandria became again the emporium of the sciences and arts.

158. Medicine, in particular, was taught there with much success. Students from all quarters of the globe resorted to it to receive the instructions of the most celebrated masters in the world; and this school, which had been founded in the happiest age of Greece, was still enjoying an undiminished degree of credit when the conquest of Egypt by the Saracens took place.

159. Amron, who commanded the expedition, was desirous to save the library; the answer of Omar is well known. Thus a treasure of incalculable value to the whole human race perished through the barbarous fury of Mussulmans.

160. Yet the proscription was less general with respect to books of medicine, of natural history, and of natural philosophy. Some few escaped destruction either on account of the interest which the most stupid men take in the science which promises them health or an alleviation of their complaints; or, as some writers are of opinion, on account of the idea which generally prevailed in the east, that they would learn from them the art of making gold.

161. The first versions of these books which appeared were in the Syriac language; for the Arabian translations are of a later date. The works of Aristotle and Galen were those for which the Arabians evinced the most enthusiastic admiration. They translated them with the greatest care, and commented on them in different ways and with different views. Their subtle minds were admirably adapted for the Peripatetic system of metaphysics, and for that farrago of abstract propositions which bears down the small number of just and ingenious views it contains. Their literati, who were as fond of pillage as their warriors, appropriated to themselves the ideas that were to be found in works

allowed such a precedency; and, were it to be granted, there is no none so richly endowed with distinct names for diseases as to enable it to specificate every complaint of which a system of nosology is expected to treat. Dr. Macbride has made a trial of our own tongue, and has completely failed; for the generic terms, under several of his orders, are entirely exotic, and under most of them very considerably so, being partly Greek, partly Latin, and partly English, uncouthly mixed together for the sake of convenience, like foreigners from all countries at a Hamburg hotel.

225. Our choice, therefore, is limited to the Greek and Latin, which have for ages maintained so equal a sway in the province of medicine, that they must still be allowed to exercise a joint control. It is a singular fact, that the Greek has furnished us with by far the greater number of terms that distinguish the higher divisions of systematic nosology, the classes, orders, and genera; and the Latin those employed to indicate the species and varieties. The systems of Linnæus and Darwin offer, perhaps, the only exception to this remark; for here we meet with attempts to use the Latin tongue alone, or at least to give it a considerable preponderancy. These examples, however, have not been followed, and are not likely to be so. The greater flexibility, indeed, and facility of combination belonging to the Greek has, on the contrary, induced almost all other nosologists, as well as almost all other men of science, to turn to it for assistance far more frequently than to the Latin. The author has availed himself of this general taste; and, by an occasional revival of terms which ought never to have been dropped, has been able so far to simplify the nomenclature of his classes, orders, and genera, as to render them exclusively Greek; and consequently to take his leave, thus far, of all other languages whatever. The changes introduced for this purpose are by no means numerous, and will in no instance, as he trusts, betray affectation or coercion. His authorities will usually be found in Celsus or Galen, who have carefully handed down to us the distinctive terms both of the earlier and the later schools of Greece; and, if at any time he has had occasion to wander farther, he has usually supplied himself from Aëtius, Cælius Aurelianus, Dioscorides, or Aristotle. The sources, however, from which he has drawn, are in every case indicated, and, he ventures to hope, will be generally approved. Concerning the specific names he has been less scrupulous; and has allowed those to stand, whether Greek or Latin, that are already in most common use; or has drawn from either language such as may most fitly express the essential character, wherever such character can be traced out. Yet even here he has never wandered from the Greek farther than into the Latin.

226. (2). The machinery of every art or science becomes simpler, and its auxiliary powers fewer and less needed, as it advances towards perfection. It is the same with their technology. While we are but loosely acquainted with the principles of an art we speak of them with circumlocution, and employ more words than are necessary, because we have none that will come immediately to the point. As we grow more expert we learn to make a selection; we give to many of them a greater degree of force and precision; and separate those that are thus rendered of real value from the 'leather and prunello,' the heavy outside show of useless and unmeaning terms with which they are associated; and thus gain in time as well as in power. In unison with these ideas the author, as soon as he has pitched upon a word that will best answer his purpose, will be found, as he hopes, to adhere to it wherever he has had occasion to advert to the same idea, without indulging in any play of synonyms, or different terms possessing the same or nearly the same meaning. Marisca and hæmorrhois have been equally employed by medical writers to distinguish the disease which we call vernacularly piles. The first is a Latin term, and refers to the tubercles of the disease, and the second a Greek, and refers to a discharge of blood which occasionally issues from them. As commonly used they are direct synonyms notwithstanding this difference of radical meaning, and either might answer the purpose; the diversity of the disease being pointed out by distinctive adjuncts, as cæca, mucosa, or cruenta. Sauvages and Sagar, however, have employed both; but have labored to establish a difference, without having succeeded even in their own judgment. So that, in these writers, we have one and the same disease described under two distinct genera in distinct classes; the first occurring in Sauvages under class i. ord. v. entitled, vitia, cystides: the other under class iv. ord. ii. entitled fluxus, alvifluvus, and introduced with this remark, 'hæmorrhoides vero nihil aliud sunt quam mariscæ, gazæ apud Aristotelem.' In the present system marisca is alone retained; and the author has preferred it to hæmorrhois, first, because hemorrhage is only a symptom that characterises a peculiar species, or rather, perhaps, a variety of the disease; and next, because hæmorrhois, or rather hæmorrhoidæ (αιμορροιδαι), was employed among the Greeks, as well vulgarly as professionally, in a much wider sense than that of modern times, and imported flux of blood from the vagina, as well as from the anus; and, in fact, from any part of the body, when produced by congestion and consequent dilatation of the mouths of the bleeding vessels, which were supposed in every instance to be veins. So Celsus, 'Tertium vitium est, ora venarum tanquam capitulis quibuscum surgentia quæ sæpe sanguinem fundunt: αιμορροιδας, Græci vocant. Idque etiam in ore vulvæ fæminarum incidere consuevit.' To the same effect Hippocrates, Lib. de Morb. Mulier. Galen uses it in a still wider extent, De Morbis Vulgaribus: and hence the woman with an issue of blood in St. Matthew, ch. ix. 20, is termed in the Greek text γυνη αιμορρουσα. Gaza (γαζα), the term used by Aristotle, would have answered as well as marisca, but that it is less common in the present day, and an exotic term even in the Greek. Hesychius calls it a Persian word, and Scaliger coincides with him; translating it, 'thesaurus, reditus, tributus,' 'a treasury,' or place of deposit or accumulation, chiefly of tri-

bute or taxes. It is rather an Arabic than a Persian term, though both countries use it under different inflexions. The Arabic root is khazi, 'a blush or ruddy flush,' whether from fulness, shame, or modesty; whence the verb khaza, to produce blushes, erubescence, or suffusion;' and hence khazan in Persian signifies 'autumn, or the season of fulness and erubescence;' while khazain in Arabic is 'a garner, treasury, or repository for the fulness of the autumnal months;' literally cella, cellula, gaza, or gazophylacia, as explained by Hesychius.

227. Vogel and Plenck are overloaded with synonymous terms, or what may, for common purposes, be so regarded; and perpetually aiming, like Sauvages, in the preceding instance, to discover a distinction where none exists, they have multiplied their list of diseases, as we have already seen, almost without number. The discrimination of Cullen has here been employed to the highest advantage, and is entitled to the thanks of every one. Celsus is in this respect peculiarly correct; he adheres to the best technical term supplied by his own tongue; and, though he carefully gives us its Greek synonym, he never changes it for any other term, whether Greek or Latin.

228. (3). In improving the technology of an art or science it seems of great importance not only that all unnecessary terms should be banished, but that those retained should be simplified and abbreviated as much as may be without injuring their force or precision. Nothing can be more repulsive to the eye of a learner, or more inconvenient to the memory of an adept, than the long cacophonous compounds with which the science of nosology has been loaded by several German writers; such as the pothopatridalgia of Zwinger, for which, to the consolation of every one's lips and ears, Nenter auspiciously invented nostalgia; the ancyloblepharon, hydrenterocele, and others already noticed of Vogel, for which it is scarcely worth while to look for better to supply their place, as they import mere shadows of real diseases; and such specific epithets as spondylexarthreticus and hydrocatarrhophicus, employed in the nosology of Plouquet, but far more likely to produce than to remove confusion. To this point the author has endeavoured to keep his eye steadily directed; he has avoided compound terms as much as possible; and, when compelled to have recourse to them, has aimed at restraining them within compass.

229. Much of the character of words in respect to dimensions and euphony, as well as to precision, depends upon the common prefixes and suffixes which it is occasionally found necessary to employ; and which in some branches of science, and especially in that of chemistry, create and regulate considerably more than half their nomenclature.

230. This subject opens a wide field, though the consideration of it, for the present, must be confined to a very narrow compass. It is altogether new, not only to medicine, but, as far as the author is acquainted, to Greek philology; at least, after an extensive enquiry, he has not been able to obtain any assistance from books professedly devoted to it. There seems much reason to believe that the auxiliary parts of every compound term, not only in medical technology, but through the whole range of the Greek tongue, had, when first employed, distinct and definite meanings, and limited the radicals, with which they were associated, to peculiar modifications of a common idea. To these meanings we can still trace many of them, though the greater number, like most of the elements in the Chinese characters, have passed through so many changes, that it is difficult, and in some instances perhaps impossible, to follow up the analysis to their original sources. From the novelty of the subject the author has, perhaps, a fair claim upon the reader's indulgence; the enquiry, however, is worthy of being carried much farther than he has time or limits to pursue it; and he hopes, and has reason to believe, that it will be thus extended, before long, by a friend, who has far more competency for the purpose than he can pretend to.

231. The suffixes employed in medical technology are more numerous than the prefixes, and the following is a list of those in most common use:—

Greek	Agra	αγρα
	algia	αλγια
	asma	ασμα
	asmus	ασμος
	esmus	εσμος
	ismus	ισμος
	osma	οσμα
	cele	κηλη
	copus	κοπος
	esis	εσις
	iasis	ιασις
	itis	ιτις
	odes	ωδης
	odynia	οδυνια
	osis	ωσις
	rhagia	ραγια
	rhoea	ροια
Latin	igo	
	ula	
	illa	
	ularis	
	illaris	
	osus.	

232. The common prefixes are uniformly Greek, and are as follow:—

A	α
apo, ap'	απο, απ'
aph'	αφ'
caco, cac'	κακο, κακ'
cata, cat'	κατα, κατ'
dia	δια
dys	δυς
ec, ex	εκ, εξ
en	εν
epi, ep'	επι, επ'
eph'	εφ'
hyper	υπερ
hypo	υπο
para, par'	παρα, παρ'
peri	περι
syn, sym, sy'	συν, συμ, συ'.

233. These auxiliaries are far too numerous, and, in the course of the vocabulary, recur far

too frequently. Some of them however may be suppressed, as synonyms or duplicates of others; while it should be a rule never to employ any one of the remainder but when absolutely necessary to distinguish the compound into which it enters from the root itself, or from another compound derived from the same root, by the addition of an idea to which it is uniformly restricted.

234. Algia, copus, and odyne, are direct synonyms; to which may also be added agra, for, though of a somewhat different radical meaning, it is commonly superadded, like all the three former, to express the general idea of pain or ache. And hence, very much to the perplexity of the learner and the incumbrance of the technical vocabulary, we have cephal-algia for head-ache, gastr-odyne for belly-ache, chir-agra and pod-agra for gout-ache in the hand or foot. And, worse than this, we have ost-algia, ost-odynia, ost-agra, and osto-copus, to signify one and the same affection of the bones. Now it may be necessary to retain algia, which is perhaps the most popular of the whole, but we should as far as possible banish all the rest; and with the exception of agra in the single instance of pod-agra, which cannot readily be dismissed, none of the others will be met with in the course of the ensuing arrangement. Parodynia will indeed be found, but in this case odynia is the root itself.

235. Esis, osis, itis, oma, and iasis, have been employed perhaps for ages, and several of them very generally throughout the Greek tongue, as mere terminations, without any direct reference to their origins: and probably without a recollection or belief that they have any significant origins, or that those origins can be traced: in which case they would become simple terminating synonyms, and, in the abbreviating aim of a technical nomenclature, ought to follow the fate of the generality of the preceding list. Some of them, indeed, can well be spared; but accident, or a cause not easy to be explained, has given a peculiar and useful meaning to others, though very different from their radical sense, and these may be advantageously retained. The first three are probably derived from εω or its different compounds, and together with the Latin term igo, which is perhaps a corruption of ago, imply the common idea of 'ago, mitto,' 'motion, action, or putting forth,' and consequently, in medical combination, of 'morbid motion or action.' Esis (εσις) is a direct derivative from εω, as is obvious in paresis, literally 'submissio,' 'remissio,' 'laxatio,' 'restraint or inability' of 'moving or putting forth;' whence by Aretæus, and various other Greek writers, it is used synonymously with paralysis. We meet with the same word and the same radical idea in proesis, synesis, and other compounds of the same root. Osis (ωσις or ουσις) descends in like manner from ειμι, 'sum,' itself a derivative of εω; whence osia or ousia (ωσια or ουσια) is literally 'ens, essentia, substantia,' the thing put forth 'in being, action, or motion.' Itis (ιτης) is as clearly an immediate derivation from ιεμαι; itself, like the preceding, a ramification from εω, and imports, not merely action, but, when strictly true to itself, 'impetuous or violent action' The literal rendering of ιεμαι is 'feror impetù,' and that of ιτης is, 'temerarius, audax, præceps periculorum.' While the direct origin of igo betrays itself in all its compounds, for vertigo (deriving igo from ago) is literally 'rotatory motion or dizziness;' serpigo, 'serpentine motion or course,' peculiarly describing a particular modification of herpetic eruption to which the term serpigo is applied.

236. Iasis, and oma, convey different ideas as issuing from different radicals. Iasis (ἰασις) is literally sanatio, from ἰαομαι, 'sano, medeor,' and hence necessarily imports, in composition, 'medendus,' or 'ad sanationem spectans.' Oma (ὠμα) is as obviously an inflection of ὠμος, 'crudus, ferus, imperfectus,' as is its real meaning in sarc-oma, distinctly 'crude, wild, imperfect flesh:' ather-oma, 'crude, incocted pulp or pap.' But if oma be preceded by the letters pt, as in ptoma (πτωμα) it is then derived from πιπτω, 'procido,' and constantly imports procidence or prolapse; as in pro-ptoma, 'a prolapse of any part;' archo-ptoma, 'a prolapse of the anus.' This is sometimes written ptosis, as in colpoptosis, 'a prolapse of the vagina;' hysteroptosis, 'a prolapse of the uterus:' but for the sake of perspicuity, and especially to the learner, one mode only ought to be adhered to, and perhaps the first is the best.

237. Asma (ασμα) is strictly 'incantamentum,' enchantment, incantation; and, in a looser sense, possession, seizure. Osma, asmus, esmus, and ismus, are mere varieties of asma; and that they were at first intended to denote this idea we may judge from the terms phantasma, enthusiasmus, phricasmus, marasmus, phrenismus, priapismus. It became long afterwards a terminal member of tenesmus, rheumatismus, ptyalismus, when the original sense was nearly or altogether lost sight of. And since this period the entire group have been employed not only so generally, but in such a multiplicity of senses, that we can neither banish them nor define them; whence, like esis and osis, they must remain to be had recourse to as mere final adjuncts whenever necessary, though the less frequently employed the better.

238. It is clear, then, as well from actual analysis as from the genius of the Greek tongue itself, that each of these terminations had a distinct signification when first introduced; although it is equally clear that most of them have for some centuries been employed loosely and indiscriminately as mere final syllables. In many instances none of them are wanted; and in all such cases they ought, unquestionably, to be dropped as redundant; and, occasionally, they have been so. Thus the myopiasis of Vogel is advantageously shortened by Plenck to myopia, as at first written by Linnæus; and, for the same reason, mydriasis ought to have been written mydria. So chlorosis, if it were to be formed in the present day, would be chloria, and exoneirosis, exoneiria. Many of the terms introduced by Dr. Young seem to be formed directly upon this basis, and are highly entitled to attention; as phlysis, palmus, pneusis.

239. In various instances, again, we find, as

already hinted at, several of the terminations, apparently from some accidental cause, taking a peculiar bearing which it would be right to encourage, as long as they are retained, so as to give them a direct and definite sense. Such especially is the case with itis, which, from the time of Boerhaave, has been progressively employed to express organic inflammation, as in cephalitis, carditis, gastritis, and most similar affections. In this sense, therefore, when employed at all, it ought to be employed exclusively. And here the etymological idea is directly consonant with the practical: for, as observed already, it imports increased and impetuous action. A few terms only stand in our way, upon this point, even at present, as rachitis, hydrorachitis, ascites, and tympanites; all which, however, are of little consequence, as they have good synonyms, or may be easily varied, as the reader will perceive in the ensuing arrangement.

240. Oma has, in like manner, from some cause or other, a general idea attached to its use, not easy to be explained from its primary signification: it is that of external protuberance, and to this, therefore, it should be confined. We meet with this idea in ecchymoma, staphyloma, atheroma, steatoma, sarcoma, and carcinoma. It does not easily apply to glaucoma; but as this was as frequently called by the Greeks glaucosis, and by the Romans glaucedo, we need not be troubled even with this slight exception. The therioma of Celsus, though continued by Vogel, is banished from general use; and, if it were not, this would also admit of a ready change to theriosis.

241. Iasis is almost as generally appropriated in the present day to denote diseases of the skin, unconnected with fever; the cause of which it seems, also, as difficult to discover as in either of the preceding instances: but, this being the fact, the hint should be taken and the necessary limit applied. We have sufficient exemplification of this remark in elephantiasis, leontiasis, psoriasis, pityriasis, phthiriasis, helminthiasis (applied by Plenck to cutaneous worms and larves of all kinds, except those of the pediculus, but to which malis is preferable) and tyriasis, importing in the same author a peculiar variety of lepra. To these we may add ichthyiasis, as in this case it ought to be written, instead of ichthyosis. Many of these terms are unnecessary, and may be well spared, but they serve as examples of the general turn the final iasis has been lately taking, and to which, whenever it is made use of, it would be right to attend. Satyriasis, sardiasis, and one or two other terms, form exceptions to the general tendency; but they are not wanted, as will be readily perceived in the ensuing pages; while all but the first have been long obsolete, and are almost forgotten. Hypochondriasis is not, strictly speaking, a Greek term. It is comparatively of modern origin, and may be conveniently exchanged for hypochondrias.

242. Cele (κηλη) retains generally, to the present hour, its original sense, which is that of 'a yielding tumor,' especially a yielding tumor produced by the protrusion of a soft part; as in bronchocele, sarcocele, glossocele, bubonocele. Rhagia (ραγια) is, properly speaking, an elision of hæmorr-rhagia, from 'ρησσω, 'rumpo,' to burst or break; and hence uniformly denotes a preternatural flux of blood by the bursting o. one or more blood-vessels, as in menorrhagia, rhinorrhagia, and enterrhagia. While rhœa ('ροια), from 'ρεω 'fluo,' to flow, imports, with almost equal uniformity, a preternatural flux of any other fluid, as in diarrhœa, gonorrhœa, leucorrhœa, ottorrhœa. In perirrhœa, as employed by Hippocrates in the sense of enuresis, we have an exception, as we have also in the modern compound menorrhœa, which denotes a natural flux, and in a healthy proportion. But the first has long grown obsolete and yielded to enuresis; and for the second we may employ catamenia, or menia without the preposition, which is totally superfluous, and omitted in all the compounds of μην, as also in the Latin homonyms menses and menstruatio. All these therefore may remain untouched, and are sufficiently correct in their present use.

243. Odes (ωδης) uniformly imparts 'par, similis,' like or akin, to the subject with which it is connected, as in typhodes, icterodes, phlegmonodes: and is probably derived from ωδε, 'hoc modo.'

244. Illa, ula, illaris, ularis, well known as Latin diminutive terminations, are perhaps derived, as will be more particularly shown hereafter, from the Greek υλη (yle or ule), 'materies,' and import, therefore, 'of the matter, make, or nature of,' as in pupilla or pupula, pustula, fibula. These are opposed by the suffix osus, uniformly a Latin augment, derived perhaps, like osis above, from ωσια or ουσια, 'substance, essence, power:' hence undula is 'a little wave;' undosus 'full of waves;' cellularis 'having little cells;' cellulosus 'full of little cells.' This distinction has not been sufficiently attended to by medical writers, and we have in consequence seen the two suffixes occasionally confounded.

245. The prefixes or initial particles or propositions have far less generally departed from their original sense, though many of them exhibit great looseness, and very different significations. In grouping them we shall find that a, caco, dys, and para, though separated from each other by shades of difference, are all privative or debasing; and that ec, ex, epi, hyper, though separated in like manner, are all augmentative or elevating. It would be better perhaps that *a* should be limited to the idea of total privation, as in agenesia, or aphoria: but the laxity of its use, not only through the whole nomenclature of medicine, but the whole of the Greek tongue, is an effectual bar to such an attempt, as we may readily perceive in atonia, apnœa, adipsia, asthenia, in which it is merely debasing or defective: and it is in this sense that it often becomes synonymous with dys, para, and caco, as in dyspnœa, paralysis, and cacodia (defective power of smelling). Dys, indeed, in its strictest sense, should convey the double idea of defect with difficulty or distress, as in dysenteria, and dysmenorrhœa; and caco the double idea of defect with corruption or depravity, as in cachexia, cacophonia: but this distinction has been little

attended to. Para occasionally embraces a wider range than any of the rest, and runs precisely parallel with the Latin malè, or the Teutonic mes, or mis, so frequent in compound words of our own and the French tongue. In anatomy, however, para is often employed in the sense of apud or juxta, 'bordering on, or hard by'—and in words derived from anatomy it retains this sense in the vocabulary of diseases, as in parotis, paronychia, with no small confusion to the learner: and consequently gives a sense that should be otherwise provided for.

246. It would be better still to avoid the use of all these prefixes as much as possible, with the exception of *a*, which cannot be spared; for, where they convey the direct sense of *a* they are not wanted, and, where they convey no other than that of general morbid action, they are commonly, though not always, superfluous expletives; since the science, in whose service they are thus employed, necessarily implies such an idea, as well without them as with them.

247. The opposite initials ec, or ex, epi, or eph', and hyper, denote alike the general idea of out of, outwards, over, above, in their primary sense, or when applied to place, as in ectropium, epidemicus, hyperostosis; but that of augmentation or excess in their secondary sense, or when applied to quantity or quality, as in ecstasis, epiphora, hyperuresis.

248. En is an initial of very extensive range as well as signification; and it has this peculiar property, that, in different senses, it becomes an antagonist to both the preceding groups in the one or other of their general meanings. In its primary sense, or as applied to place, it imports within, below; as in encephalon, emphysema; and consequently opposes the primary sense of ec, epi, hyper: while in its secondary sense, or as applied to quantity or quality, it exactly accords with these prepositions, and imports superiority or excess, and in like manner opposes the general idea conveyed by *a*, caco, and dys; of which we have examples in enthusiasma and enuresis. En appears therefore to be as necessary an initial particle in the medical vocabulary as *a*; and with these two we should seldom feel at a loss for any other; for as *a* is capable of supplying the place of all the rest in the first set, so en is capable of performing the same office for those of the second. Hypo (υπο), in its signification of below or downwards, is sometimes called upon to act the part of an ally, as in hypogastrium, and hypocondrium, and their derivatives hypogastrocele, and hypocondrias or hypocondriasis; but this is seldom the case, and at all times obtrudes an assistance of which en is not in want: whence hypo might easily share in the preceding proscription. In this general view of the subject, en seems at first sight to be untrue to itself: but it is not difficult to explain the apparent contradiction. En runs precisely parallel with the Latin altè. The leading idea of both is 'power or precedency;' and this, whether the order of advance be from below upwards, or from above downwards. In measuring rank and station, we take the former scale, and speak of high posts and dignities; in measuring intellectual qualities we take the latter, and speak of profound judgment and wisdom. The Greek en and the Latin altè are equally applicable to both; and hence it is that in our own tongue, and indeed in most of the dialects of Europe, high and deep occasionally becoming synonyms, and the same general meaning may be expressed by either. In one respect, indeed, the Greek and Latin terms differ; the former importing depth in its primary, and height in its secondary sense; and the latter importing height in its primary, and depth in its secondary sense. In all these cases, however, the difference of the two meanings is easily understood by the context, and it would be hardly worth while to attempt to limit the Greek en to either sense if we were able. *En* is a short and tractable intitial, and must remain equally to form a contrast with *a*, and with *ex* or *epi*; in the former case to import ascendancy or superiority, as being applied to quantity or quality; and in the latter case to import descendancy or inferiority, as being applied to place; with which distinction before us its meaning can never be mistaken.

249. A word or two will suffice for the remaining prefixes. Cata (κατα) and apo (απο) are two of the most frequent. They have been very little introduced into nosological terms of late; but in those of early writers are far more frequent, and exhibit a great variety of senses; most of which, however, in respect to either prefix, are capable of being resolved into the general idea of iteration or duplicate action, or ideas that obviously ramify from this fountain, and which are usually expressed by the Latin and English particle *re*; as in catapsyxis, re-frigeration; cataspasma, re-traction; catamenia, re-menstruation (importing its regular return); apostema, re-cession, abscession or abscess; apothesis, re-placement or reduction of a dislocated bone. Whence again *apo* is generally used in the sense of back or from, as in apogeusia, apositia, backward, tardy, defective taste or appetite; while both are far more frequently used emphatically or in a superlative sense, as importing reduplicate action or double force; of which we have examples in catacauma, a burn; catagma, a fracture; catalysis for paralysis, catarrhus, apoplexia, apocyesis (parturition). In this signification both are evidently redundant; nor are they much marked in any other.

250. Peri (περι) continues uniformly true to the sense of circum, and is limited to terms derived from anatomy, as peripneumonia and peritonitis. Dia (δια) is nearly as single in its meaning; or rather the different significations in which it is used are capable of being arranged under one leading idea, that of separation, which is the only idea it should be allowed to convey, if ever employed in the coinage of new terms. We trace this general sense in diabetes and diarrhœa, 'a passing off, or flowing through;' diacrisis and diagnosis, 'a judgment or distinction, by the separation of one symptom from another;' diastole and diastasis, a dilatation or separation of part from part.' Syn (συν), and its derivatives sym and sy, are uniformly expressive of conjunction or association.

251. Such are the significations assigned to these auxiliaries whenever employed in the en-

suing system; the author has nevertheless endeavoured to employ them as seldom as possible, and always in a definite sense. The classific names are given entirely without them, and the ordinal nearly so. In this respect he has differed from Dr. Young, who has prefixed the preposition para, importing diseased action, to the name of every class but the last, in which it is exchanged for ec. But this seems a pleonasm; for, in a system directly nosological, para is necessarily implied in every instance. Neuroses or neurismi is just as expressive as paraneurismi; and hæmorrhagiæ or hæmasiæ, as parhæmasiæ. Linnæus has been very particular upon this point, and has never introduced compound terms but when he has thought them strictly called for. In consequence of which we have mentales, quietales, motorii, without any affix whatever.

252. But though the author has felt no occasion for these auxiliaries in denominating his classes, and but little occasion for them in the names of his orders, in his generic terms he has often found it necessary to have recourse to such assistance; in some instances because, though evidently redundant, the affix could not be detached without the appearance of affectation; but more frequently for the purpose of distinguishing the names of different diseases, compounded of the same radical term; as in phyma, écphyma, and émphyma; phlysis, écphlysis, and émphlysis; ecpyésis and empyésis with various others; which, thus compounded, present, at the same time, their relative points of accordancy and of discrepancy, and are consequently more easily, instead of less easily, distinguishable.

253. (4.) As the component parts of a term ought to be restricted to a precise and individual meaning, so ought the entire term, whether compound or single. The common signification of asphyxia is 'apparent death,' whether from suffocation, electricity, or any other cause. Plouquet, in his Initia, has applied this term to a 'temporary suspension of the pulse, while all the other functions of the system, whether corporeal or mental, continue with little or no interruption.' The term, in its original sense (ασφυξια), pulselessness, will bear Plouquet's meaning; but it is at the expense of its general interpretation: and hence, as the disease alluded to by Plouquet has not yet fairly found a place in nosology, and no other term has been devised for it, it will be found distinguished from asphyxia in the present system by the term acrotismus, of meaning precisely parallel.

254. There is a strange confusion in the general use of the terms hemeralopia and nyctalopia. Most modern writers mean by the first, 'vision, irksome or painful, in the light of noon, but clear and pleasant in the dusk of the evening;' and, by the second, 'vision dull and confused in the dusk, but clear and powerful at noon-day.' But this is directly to reverse the signification of both terms, as employed by Hippocrates and the Greek schools; and, as the Greek sense is still occasionally continued, there is sometimes no small difficulty, and especially to a learner, in understanding what diseases are referred to. In the ensuing system most disorders of the sight, unconnected with inflammatory action, are arranged under a common genus, entitled paropsia, of which hemeralopia and nyctalopia become species; and as they are here distinguished by the names of p. lucifuga, and p. noctifuga, it is hoped that the usual perplexity will be found sufficiently avoided.

255. Æsthesia, among almost all the nosologists, imports sensation generally: and hence dysæsthesiæ is employed by Sauvages, Vogel, Sagar, and Cullen, as the name of an order comprising diseases of sight, smell, taste, touch, and hearing; running parallel with the order æsthetica, in the class neurotica of the present system. But Cullen, after having used the term as an ordinal name in this general signification, next employs it as the name of a distinct genus, in the very limited signification of touch alone, and in contrast with all the other senses; anæsthesia, the genus referred to, being defined 'tactus imminutus vel abolitus.' Linnæus, indeed, had already used it with an equal restriction, which he ought not to have done, as the term had been already adopted by Sauvages in its wider and correcter sense. But Linnæus has not fallen into the self-confusion of Cullen, for he has not employed æsthesia or any of its compounds in any other import. To avoid this irregularity, the anæsthesia of Linnæus and Cullen is, in the present system, exchanged for parapsis.

256. Exanthema, among the Greeks, imported 'cutaneous eruptions generally.' Sauvages, and all the nosologists down to Cullen inclusively, together with most other medical writers, have limited it to express 'cutaneous eruptions accompanied with fever.' Attempts have more lately been made to fetter it within a still narrower circle; sometimes by confining it to eruptive fevers produced by specific contagion, whatever be the character of the efflorescence: and sometimes by restraining it to the character of the efflorescence alone, with little attention to its being connected or unconnected with fever. It is in this last view that the term has been employed by Dr. Willan, who limits it to the import of the English term rash, and in his list of definitions explains the one term by the other. In this confined use of the word, however, he does not always maintain his accustomed precision; for after having, in his table of definitions, characterised rash or exanthem as distinct from papula and wheal, he employs exanthemata as the name of an order, embracing diseases by both these symptoms. In Dr. Willan's very restricted use of the term there is great inconvenience, and but little or no authority in his favor; and hence in the ensuing system it is restored to its common nosological acceptation.

257. The limits of the present sketch will not allow the author to pursue this subject much further; but it is necessary to observe, before he entirely drops it, that there are various terms in common use in nosological descriptions, whose meaning in like manner remains in a very unsettled state to the present hour; and which it will be the object of the ensuing attempt to simplify and define. As examples, it may be sufficient to glance at the words pyrexy, apyrexy paroxysm, accession, exacerbation, crisis.

258. Fevers were called by the Greek physicians pyreti, pyrectici morbi, or simply pyrectica. Pyrexia (febricitatio, rather than febris), was in a looser sense applied to fever generally, but limited, when more strictly employed, to febrile heat and increased pulsation. The duration or the cold and hot stages was called its paroxysm, and the interval between one paroxysm and another was distinguished by the term apyrexy (απυρεξια). What the Greeks called paroxysm, the Latins named accession (accessus, or accessio); for the apyrexy of the former, the latter employed the term intermission (intermissio), and if the interval were only a remission, instead of a perfect intermission, the return of the hot fit was denominated exacerbation (exacerbatio); which in fact is a direct translation of paroxysm; so that an exacerbation was the same correlative to a remitting as an accession was to an intermitting fever. The duration of a single exacerbation and its remission, or of a single accession and its intermission, was denominated a febrile period.

259. Sauvages employs the whole of these terms with a pretty strict adherence to their original meaning; but by Cullen and still later writers they have been used with much greater laxity, and occasionally in very different senses. Like many of the Greek physicians, Dr. Cullen has proposed a difference between pyrexy and pyretus or febris; the former of which terms he is well known to have taken as the name for his first class of diseases. While, however, he proposes a difference between these terms, it is not that of the Greek schools, but altogether of his own invention; for instead of limiting pyrexy, as was done by the Greeks when they allowed a distinction, to the mere symptoms of increased heat and increased pulsation, corresponding in a considerable degree with what is now usually called the second stage of a febrile paroxysm, he has connected shivering, or the chief symptom of the first stage, with it, together with the symptoms of 'various injured functions, and diminished strength in the limbs.' By this addition, however, he has considerably overshot his own mark; for he has not only given a new sense to the term, but has frustrated the distinction he intended to establish; insomuch that, when he proceeds to define fever by its ordinal character he has nothing of any real importance to add; for fever in his ordinal definition of the term is still pyrexy, though pyrexy with the comparatively trivial appendage of 'previous languor, lassitude, and other signs of debility, without primary local disease;' and hence, moreover, the term pyrexiæ, upon his own interpretation, applies but very indifferently, as a classific name, to any of Dr. Cullen's remaining orders, except exanthemata; for it is rarely that inflammations or hæmorrhages, his other orders, are preceded by shivering, or accompanied with lesion of various other functions than that belonging to the organ affected, although they usually are accompanied with 'increased heat and pulse,' or pyrexy, in the Greek restricted sense of the term. It is not to be wondered at, therefore, that this distinction of Dr. Cullen, between pyrexy and fever, should have appeared to later writers as perplexed or nugatory; and it was probably under some such feeling that Dr. Parr, and still more recently Dr. Young, in laying down their respective systems, determined upon abandoning all distinction whatever, and upon employing pyrexiæ and fevers as synonymous, or rather univocal terms. It is necessary, therefore, to point out the discrepancy that is at present prevailing in medical technology upon this subject. In the restricted sense in which the term was employed by the Greeks it seems useful and necessary; for we have no other by which we can so well or so shortly indicate those peculiar febrile symptoms which connect the family of phlogoses or phlegmasiæ with that of simple fevers; and it is in this sense, therefore, as importing the joint idea of febrile heat and augmented pulse, detached from the ideas of shivering, languor, and various injured functions, that the term pyrexy will be employed whenever had recourse to in the ensuing pages.

260. The term accession has of late years undergone a still greater change in its meaning than pyrexy. It has been just observed that accessio or accessus was employed by the Latin writers in a sense precisely parallel with the Greek word paroxysm; and that either embraced the cold and hot stages of a febrile seizure, the only stages into which such seizure was divided. And hence paroxysm is a term not to be found in Celsus, who uniformly employs accessio in its stead.

261. Among recent writers, however, and perhaps generally in the present day, while the term paroxysm is applied not merely to fever-fits, but to fits of every violent and intermitting disorder whatever, the term accession is limited to the commencement or onset of a fit, its insultus, as denominated by the Latin writers; and hence Dr. Cullen speaks of the 'accession of paroxysms,' a phraseology which would be nonsense upon the original meaning of the terms; while Dr. Turton, with evident indecision upon the subject, defines accessio, in his Glossary, 'the beginning or paroxysm of an intermitting fever' (allowing the reader to take which sense he will); and paroxysmus 'an access, fit, or exacerbation of a disease;' giving a still greater latitude, as well in respect to the genus, as the stage of the morbid affection. The Latin translators of Galen adhere to the original signification; and hence what Cullen calls the 'accession of paroxysms,' is in their language 'incrementa accessionum:' and the same import is given to the term access or accession by Sauvages, who, in describing the simple quotidian fever, says, 'duratio accessûs octodecim horas non excedit;' and observes of the quotidiana subintrans 'accessus ad viginti quatuor horas fermè extenduntur.' Even in Cullen the term seems sometimes to be employed as a synonym for paroxysm, as in his definition of hectic fever, in which accession is opposed to remission or apyrexy; while in his definitions of the tertian and quartan, in which the words paroxysm and accession are both introduced, the latter is designed evidently to import the commencement or first stage of the former, or 'the accession of the paroxysm,' as in the passage just referred to; that which by

Hoffman was elegantly and correctly denominated the spasmus periphericus, or general spasm of the small vessels diffused over the entire surface; in popular language, the shivering fit.

262. It is not difficult to account for this confusion of sense: for notwithstanding the general appropriation of the word accession among the Latin writers to the whole duration of a fever-fit, or what is now called a paroxysm, its radical idea imports simply 'advance, approach, entrance, avenue;' and in this meaning Celsus himself is perpetually using the term in its verbal form, and occasionally, indeed, in connexion with accessio in its technical signification, as 'donec altera accessio accedat,' 'till another accession accedes or comes on.'

263. Fordyce, probably from its complicate meaning, has banished the term accession altogether, and introduced the phrase cold fit in its stead, retaining, however, paroxysm in its modern and popular sense: so that, according to him, an ephemera is a fever consisting of one paroxysm, which paroxysm comprises three stages, 'a cold fit, hot fit, and crisis.' And here we have a new sense assigned to the term crisis. Among the Greeks it is very well known to have imported a decision or determination of the disease; and hence critical days were, amongst them, days which produced such decision or determination. With Dr. Fordyce, however, crisis imports nothing more than the decision or determination of a single paroxysm of a disease, its decline or sweating stage. Whilst, by many of the humoral pathologists, the term was used in a different sense from both these, and signified, synonymously with the despumatio of Sydenham, the separation and discharge of the crude and morbid material which was the supposed cause of fevers, without any reference to particular days, or particular stages of a paroxysm.

264. It is high time, then, that an exact sense should be fixed for the whole of this group of terms; and with a view of accomplishing this object, as far as he is able, the author will be found in the ensuing pages uniformly to employ, 1. Paroxysm, as importing the entire duration of a fit of acute disease of any kind, whether the interval be perfectly or imperfectly free: 2. Exacerbation, as signifying the paroxysm of a disease, whose intervals are merely imperfect or remissive; which is the strict meaning of paroxysm when literally rendered: and, 3. Accession, as indicating the commencement or onset of an exacerbation or paroxysm of any kind; which restores the term to its radical idea; whilst he has omitted the use of the term crisis, as neither wanted nor conveying in the present day any determinate sense.

Cullen's Arrangement.

Class I. PYREXIÆ. A frequent pulse coming on after a horror; considerable heat; many of the functions injured; the strength of the limbs especially diminished.

Order I. Febres. Pyrexia without any primary local affection, following languor, lassitude, and other symptoms of debility.

Sect. I. *Intermittentes.* Fevers arising from the miasma of marshes; with an apyrexia, or at least a very evident remission; but the disease returns regularly, and for the most part with a horror or trembling.

Genus I. Tertiana. Similar paroxysms after an interval of about forty-eight hours, coming on most commonly at mid-day. A tertian has either;

I. An apyrexia interposed.

1. Varying the duration of the paroxysms.

A, The tertian whose paroxysms are not extended beyond twelve hours.

B, The tertian with paroxysms extended beyond twelve hours.

2. Varying in the return of paroxysms.

C, The tertian returning every day with unequal paroxysms alternately similar to one another.

D, The tertian returning every third day with two paroxysms on the same day.

E, The tertian returning every day, with two paroxysms on every third day, and only one on the intermediate ones.

F, The tertian returning every day, with an evident remission interposed between the odd and even days, but a less remarkable one between the even and the odd days.

3. Varying in its symptoms.

G, The tertian accompanied with a disposition to sleep.

H, Accompanied with spasms and convulsive motions.

I, Accompanied with an efflorescence on the skin.

K, With phlegmasia.

4. Varying in being complicated with other diseases.

5. Varying as to its origin.

II. With the interposition only of a remission between the paroxysms.

Genus II. Quartana. Similar paroxysms, with an interval of about seventy-two hours, coming on in the afternoon.

I. With the interposition of an apyrexia.

1. Varying in the type.

A, The quartan with single paroxysms, returning every fourth day, none on the other days

B, With two paroxysms every fourth day, and none on the other days.

C, With three paroxysms every fourth day, and none on the intermediate days.

D, Of the four days having only the third free from fever, with similar paroxysms every fourth day.

E, The quartan coming on every day, with similar paroxysms every fourth day.

2. Varying in its symptoms.

3. Varying in being complicated with other diseases

II. With a remission only between the paroxysms.

Genus III. Quotidiana. Similar paroxysms with an interval of about twenty-four hours, coming on commonly in the morning.

I. With the interposition of an apyrexia.

1. Varies in being solitary.

A, Universal.

B, Partial.

2. Complicated with other diseases.

II. With a remission only between the paroxysms.

Sect. II. *Continuæ.* Fevers without evident intermission, and not occasioned by marsh miasmata; but attended with exacerbations and remissions, though not always very remarkable.

Genus IV. Synocha. Great heat; a frequent, strong, and hard pulse; high-colored urine; the functions of the sensorium a little disturbed.

Genus V. Typhus. A contagious disease: the heat not much above the natural; the pulse small, weak, and for the most part frequent; the urine little changed; the functions of the sensorium very much disturbed, and the strength greatly diminished.

The species are,

I. Typhus petechialis. Typhus for the most part with petechiæ.

Varying in degree. 1. Mild typhus. 2. Malignant typhus.

II. Typhus icterodes. Typhus with a yellowness of the skin.

Genus VI. Synochus. A contagious disease. A fever compounded of synocha and typhus; in the beginning a synocha, but towards the end a typhus.

Order II. Phlegmasiæ. A synocha fever, with inflammation or topical pain, the internal function of the parts being at the same time injured; the blood drawn and concreted exhibiting a white coriaceous surface.

Genus VII. Phlogosis. Pyrexia; redness, heat, and painful tension, of some external part.

The species are,

I. Phlogosis (phlegmone) of a vivid red color; a swelling well defined, for the most part elevated to a point, and frequently degenerating into an abscess, with a beating or throbbing pain.

The variations are, 1. In the form. 2 In the situation.

II. Phlogosis (erythema) of a reddish color, vanishing by pressure; of an unequal and creeping circumference, with scarcely any swelling; ending in the scaling off of the cuticle, in pustules, or blisters.

The variations are, 1. In the degree of violence. 2. In the remote cause. 3. In being complicated with other diseases.

The consequences of a phlogosis are, an imposthume, gangrene, sphacelus.

Genus VIII. Ophthalmia. A redness and pain of the eye, with an inability to bear the light; for the most part with an effusion of tears.

The species and varieties of the ophthalmia are,

I. Idiopathic.

1. Ophthalmia (membranarum), in the tunica adnate, and the membranes lying under it, or the coats of the eye.

A, Varying in the degree of the external inflammation.

B, In the internal coats affected.

2. Ophthalmia (tarsi), of the eye-lids, with swelling, erosion, and glutinous exudation.

II. Symptomatic.

1. From a disease of the eye itself.

2. From diseases of other parts, or of the whole body.

Genus IX. Phrenitis. Violent pyrexia; pain of the head; redness of the face and eyes; inability to endure the light or any noise; watchfulness; a furious delirium, or typhomania.

I. Idiopathic.

II. Symptomatic.

Genus X. Cynanche. Pyrexia sometimes inclining to a typhus; difficulty of swallowing and breathing; with a sensation of narrowness in the fauces.

The species are,

I. Cynanche (tonsillaris) affecting the mucous membrane of the fauces, but especially the tonsils, with redness and swelling, accompanied with a synocha.

II. Cynanche (maligna) affecting the tonsils and mucous membrane of the fauces with swelling, redness, and mucous crusts of a whitish or ash-color, creeping, and covering ulcers; with a typhous fever and exanthemata.

III. Cynanche (trachealis) attended with difficult respiration, noisy and hoarse inspiration, loud cough, without any apparent tumor in the fauces, somewhat difficult deglutition, and a synocha.

IV. Cynanche (pharyngæa) attended with redness in the bottom of the fauces, very difficult and painful deglutition, respiration sufficiently free, and a synocha.

V. Cynanche (parotidæa) with great swelling in the parotids and maxillary glands appearing on the outside: the respiration and deglutition but little injured; a synocha, for the most part mild.

Diseases of this genus are symptomatic, either from external or internal causes.

Genus XI. Pneumonia. Pyrexia, with a pain in some part of the thorax, difficult respiration, and cough. The species are.

I. Peripneumony, with a pulse not always hard, but sometimes soft; an obtuse pain of the breast; the respiration always difficult; sometimes the patient cannot breathe unless in an upright posture; the face swelled, and of a livid color; the cough for the most part moist, frequently bloody.

1. Simple idiopathic peripneumonies.

Varying in degree.

2. Idiopathic peripneumonies complicated with fever.

3. Symptomatic peripneumonies

II. Pleurisy, with a hard pulse; for the most part attended with a pungent pain of one side augmented chiefly during the time of inspiration an uneasiness when lying on the side; a most painful cough, dry in the beginning of the disease, afterwards moist, and frequently bloody

1. Simple idiopathic pleurisies.

2. Pleurisies, complicated, 1. With fever. 2. With catarrh.

3. Symptomatic pleurisies.

4. False pleurisies.

The consequences of pleurisy are a vomica or empyema.

Genus XII. Carditis. Pyrexia; pain about the heart; anxiety; difficulty of breathing; cough; unequal pulse: palpitation of the heart, and fainting.

I. Idiopathic.

II. Symptomatic

Genus XIII. Peritonitis. Pyrexia; pain of the belly, exasperated by an upright posture,

without the proper signs of other abdominal phlegmasiæ.

I. Peritonitis (propria), situated in the peritonæum, properly so called, surrounding the inside of the abdomen.

II. Peritonitis (omentalis), in the peritonæum extended through the omentum.

III. Peritonitis (mesenterica), in the peritonæum spread through the mesentery.

Genus XIV. Gastritis. Pyrexia inclining to a typhus; anxiety; pain and heat of the epigastrium, augmented when any thing is taken into the stomach; an inclination to vomit, and an immediate rejection of every thing swallowed; an hiccough.

I. Idiopathic.

1. From internal causes.

A, Gastritis (phlegmonodæa), attended with acute pain and violent pyrexia.

2. From external causes.

B, Gastritis (erysipelatosa), with a less violent fever and pain: an erysipelatous redness appearing on the fauces.

II. Symptomatic.

Genus XV. Enteritis. Pyrexia of a typhous nature; pungent pain of the belly, stretching and twisting about the navel; vomiting; the belly obstinately bound.

I. Idiopathic.

1. Enteritis (phlegmonodæa), with acute pain, violent fever, vomiting, and constipation of the belly.

2. Enteritis (erysipelatosa), with less acute fever and pain, without vomiting; but accompanied with a diarrhœa.

II. Symptomatic.

Genus XVI. Hepatitis. Pyrexia; tension and pain of the right hypochondrium; sometimes pungent like that of a pleurisy, but more frequently obtuse; a pain reaching to the clavicle and top of the right shoulder; a difficulty of lying on the left side; dyspnœa; dry cough, vomiting, and hiccough.

Genus XVII. Splenitis. Pyrexia; tension, heat, and swelling of the left hypochondrium, the pain increasing by pressure; without the signs of nephritis.

Genus XVIII. Nephritis. Pyrexia; pain in the region of the kidney, often following the course of the ureter: frequent discharge of urine, either thin and colorless, or very red; vomiting; stupor of the thigh; with a retraction or pain of the testicle of the same side. The species are,

I. Idiopathic. Spontaneous.

II. Symptomatic.

Genus XIX. Cystitis. Pyrexia; pain and swelling of the hypogastrium: frequent and painful discharge of urine, or ischuria; and tenesmus. The species are,

I. Those arising from internal causes.

II. Those from external causes.

Genus XX. Hysteritis. Pyrexia; heat, tension, swelling, and pain of the hypogastrium; the os uteri painful when touched; vomiting.

Genus XXI. Rheumatismus. A disease arising from an external and frequently very evident cause; pyrexia; pain about the joints, frequently following the course of the muscles, infesting the knees and other large joints rather than those of the feet or hands; increased by external heat. The species are either idiopathic or symptomatic. The former varies in situation.

A, In the muscles of the loins.

B, In the muscles of the coxendix.

C, In the muscles of the breast.

Genus XXII. Odontalgia; a rheumatism of the jaws from a caries of the teeth.

Genus XXIII. Podagra. An hereditary disease, arising without any evident external cause, but for the most part preceded by an unusual affection of the stomach; pyrexia: pain of a joint, for the most part of the great toe of the foot, at last infesting chiefly the wrists and ancles; returning at intervals; and often alternated with affections of the stomach and other internal parts.

I. Podagra (regularis), with a pretty violent inflammation of the joints remaining for some days, and by degrees going off with swelling, itching, and desquamation of the affected part.

II. Podagra (atonica), with an atony of the stomach, or some other internal part; and either without the usual inflammation of the joints, or only with slight and wandering pains; and frequently alternated with dyspepsia, or other symptoms of atony.

III. Podagra (retrograda), with the inflammation of the joints suddenly disappearing, and an atony of the stomach and other parts immediately following.

IV. Podagra (aberrans), with the inflammation of an internal part either preceding or not, and suddenly disappearing.

Genus XXIV. Arthropuosis. Deep, obtuse, and long-continued pains of the joints or muscular parts, frequently following contusions; with either no swelling, or a moderate and diffused one; no phlogosis; pyrexia, at first gentle, afterwards hectic, and at length an imposthume.

Order III. Exanthemata. Contagious diseases; affecting a person only once in his life; beginning with fever; after a certain time appear phlogoses, for the most part small and in considerable number, and dispersed over the skin.

Genus XXV. Erysipelas. A synocha of two or three days, for the most part attended with drowsiness, often with a delirium. In some parts of the skin, most frequently the face, appears a phlogosis. The species are,

I. Erysipelas (vesiculosum), with erythema, redness creeping, occupying a large space, and in some parts ending in large blisters.

II. Erysipelas (phlyctænodes), with an erythema formed of a number of papulæ, chiefly occupying the trunk of the body, ending in phlyctenæ or small blisters.

The disease is also symptomatic.

Genus XXVI. Pestis. An exceedingly contagious typhus, with the highest debility. On an uncertain day of the disease buboes and carbuncles break forth. It is various in degree, but the species are uncertain.

Genus XXVII. Variola; a contagious synocha, with vomiting, and pain on pressing the epigastrium. On the third day begins, and on the fifth is finished, the eruption of inflammatory pustules, which suppurate in the space of eight days, and at last go off in crusts; frequently leaving depressed cicatrices or pockpits in the skin. The species are,

I. Variola (discreta), with few, distinct, turgid pustules, having circular bases; the fever ceasing immediately after the eruption.

II. Variola (confluens), with numerous, confluent irregularly-shaped pustules, flaccid, and little elevated; the fever remaining after the eruption.

Genus XXVIII. Varicella. Synocha; papulæ breaking out after a short fever, similar to those of the small-pox, but hardly ever coming to suppuration; after a few days going off in small scales, without leaving any mark.

Genus XXIX. Rubeola. A contagious synocha, with sneezing, epiphora, and dry hoarse cough. On the fourth day, or a little later, break forth small, clustered, and scarcely elevated papulæ; after three days going off in very small branny scales.

I. Rubeola (vulgaris), with very small confluent corymbose papulæ, scarcely rising above the skin.

Varying,

1. In the symptoms being more severe, and the course of the disease less regular.

2. In being accompanied with a cynanche.

3. With a putrid diathesis.

II. Rubeola (variolodes), with distinct papulæ raised above the skin.

Genus XXX. Miliaria. Synochus with anxiety, frequent sighing, unctuous sweat, and a sense of pricking as of pin points in the skin. On an uncertain day of the disease break out red, small, distinct papulæ, spread over the whole body as well as the face; the apices of which, after one or two days, become very small white pustules, remaining for a short time.

Genus XXXI. Scarlatina. A contagious synocha. On the fourth day of the disease the face swells a little; at the same time a universal redness occupies the skin in large spots, at length running together; after three days going off in branny scales; frequently succeeded by an anasarca. The species are,

I. Scarlatina (simplex), not accompanied with cynanche.

II. Scarlatina (cynanchica), with an ulcerous cynanche.

Genus XXXII. Urticaria. A quotidian fever. On the second day of the disease red spots resembling the stinging of nettles, almost vanishing during the day, but returning in the evening with the fever, and after a few days going off altogether in very small scales.

Genus XXXIII. Pemphigus. A contagious typhus. On the first, second, or third day of the disease, blisters break out in several parts of the body, of the bigness of a bean, remaining for many days, and at last pouring out a thin ichor.

Genus XXXIV. Aphtha. Synochus; the tongue somewhat swelled and of a livid color, as well as the fauces; eschars first appearing in the fauces, but at length occupying the whole internal parts of the mouth, of a white color, sometimes distinct, often running together; quickly growing again when taken off, and remaining for an uncertain time.

The species are, 1. Idiopathic. 2. Symptomatic.

Order IV. Hæmorrhagiæ. Pyrexia, with a discharge of blood, without any external violence: the blood drawn from a vein hath the same appearance as in phlegmasiæ.

Genus XXXV. Epistaxis. Pain or weight of the head, redness of the face; a discharge of blood from the nose.

I. Idiopathic.

Varying according to the time of life.

1. Epistaxis of young people, with symptoms of an arterial plethora.

2. Epistaxis of old people, with symptoms of a venous plethora.

II. Symptomatic.

1. From internal causes.

2. From external causes.

Genus XXXVI. Hæmoptysis. Redness of the cheeks; a sensation of uneasiness, or pain, and sometimes of heat in the breast: difficulty of breathing; tickling of the fauces; either a severe or less violent cough, bringing up florid and frequently frothy blood.

The idiopathic species are,

1. Hæmoptysis (plethorica), without any external violence, and without being preceded by any cough or suppression of any customary evacuation.

2. Hæmoptysis (violenta), from external violence applied.

3. Hæmoptysis (phthisica), after a long continued cough, with a leanness and debility.

4. Hæmoptysis (calculosa), in which some calculous molecules, for the most part of a calcareous nature, are thrown up.

6. Hæmoptysis (vicaria), after the suppression of a customary evacuation.

Besides these, there are a number of symptomatic species mentioned by different authors. The consequence of an hæmoptysis is, a

Phthisis. A wasting and debility of the body, with a cough, hectic fever, and for the most part a purulent expectoration. The species are,

I. An incipient phthisis, without any expectoration of pus.

II. A confirmed phthisis, with an expectoration of pus.

Both species vary, 1. As to their remote cause. 2. As to the origin of the purulent matter.

Genus XXXVII. Hæmorrhois. Weight and pain of the head; vertigo; pain of the loins; pain of the anus; livid painful tubercles, from which for the most part blood flows out; which sometimes also drops out of the anus, without any apparent tumor. The species are,

1. Hæmorrhois (tumens), external from mariscæ.

Varying,

A, Bloody.

B, Mucous.

2. Hæmorrhois (procidens), external from a procidentia ani.

3. Hæmorrhois (fluens), internal, without any swelling, or procidentia ani.

4. Hæmorrhois (cæca), with pain and swelling of the anus, without any profusion of blood.

Genus XXXVIII. Menorrhagia. Pains of the back, belly, and loins, like those of childbirth; an unusually copious flux of the menses or blood from the vagina. The species are,

1. Menorrhagia (rubra), bloody in women neither with child nor in child-birth.

2. Menorrhagia (abortus), bloody in women with child.

3. Menorrhagia (lochialis), bloody in women after delivery.

4. Menorrhagia (vitiorum), bloody from some local disease.

5. Menorrhagia (alba), serous, without any local disease, in women not pregnant.

6. Menorrhagia (nabothi), serous in women with child.

Order V. PROFLUVIA. Pyrexia, with an increased excretion, naturally not bloody.

Genus XXXIX. Catarrhus. Pyrexia frequently contagious; an increased excretion of mucus, at least efforts to excrete it.

The species are,

1. From cold.

2. From contagion.

Genus XL. Dysenteria. Contagious pyrexia; frequent mucous or bloody stools, while the alvine fæces are for the most part retained; gripes; tenesmus.

Varying,

1. Accompanied with worms.

2. With the excretion of small fleshy or sebaceous bodies.

3. With an intermittent fever.

4. Without blood.

5. With a miliary fever.

Class II. NEUROSES. A preternatural affection of sense and motion, without an idiopathic pyrexia, or any local affection.

Order I. COMATA. A diminution of voluntary motion, with sleep, or a deprivation of the senses.

Genus XLI. Apoplexia. Almost all voluntary motion abolished, with sleep more or less profound; the motion of the heart and arteries remaining.

The idiopathic species are,

1. Apoplexia (sanguinea), with symptoms of universal plethora, especially of the head.

2. Apoplexia (serosa), with a leucophlegmatia over the whole body, especially in old people.

3. Apoplexia (hydrocephalica), coming on by degrees; affecting infants, or those below the age of puberty, first with lassitude, a slight fever, and pain of the head, then slowness of the pulse, dilatation of the pupil of the eye, and drowsiness.

4. Apoplexia (atrabiliaria), taking place in those of a melancholic constitution.

5. Apoplexia (traumatica), from some external injury mechanically applied to the head.

6. Apoplexia (venenata), from powerful sedatives taken internally, or applied externally.

7. Apoplexia (mentalis), from an affection or emotion of the mind.

8. Apoplexia (cataleptica), the muscles remaining contractile, by external motion of the limbs.

2. Apoplexia (suffocata), from some external suffocating power.

The apoplexy is frequently symptomatic.

1. Of an intermittent fever. 2. Continued fever. 3. Phlegmasia. 4. Exanthema. 5. Hysteria. 6. Epilepsia. 7. Podagra. 8. Worms. 9. Ischuria. 10. Scurvy.

Genus XLII. Paralysis. Only some of the voluntary motions impaired, frequently with sleep.

The idiopathic species are,

1. Paralysis (partialis), of some particular muscles only.

2. Paralysis (hemiplegica), of one side of the body.

Varying according to the constitution of the body.

a, Hemiplegia in a plethoric habit.

b, In a leucophlegmatic habit.

3. Paralysis (paraplegica), of one-half of the body taken transversely.

4. Paralysis (venenata), from sedative powers applied either internally or externally.

A symptom either of an asthenia or palsy is,

Tremor; an alternate motion of a limb by frequent strokes and intervals.

The species are, 1. Asthenic. 2. Paralytic. 3. Convulsive.

Order II. ADYNAMIÆ. A diminution of the involuntary motions, whether vital or natural.

Genus XLIII. Syncope; a diminution or even a total stoppage, of the motion of the heart for a short time.

I. Idiopathic.

1. Syncope (cardiaca), returning frequently without any manifest cause, with violent palpitations of the heart during the intervals. From a fault of the heart or neighbouring vessels.

2. Syncope (occasionalis), arising from some evident cause. From an affection of the whole system.

II. Symptomatic; of diseases either of the whole system, or of other parts besides the heart.

Genus XLIV. Dyspepsia. Anorexia, nausea, vomiting, inflation, eructation, rumination, cardialgia, gastrodynia, more or fewer of those symptoms at least concurring; for the most part with a constipation of the belly, and without any other disease either of the stomach itself or of other parts.

I. Idiopathic.

II. Symptomatic.

1. From a disease of the stomach itself.

2. From a disease of other parts, or of the whole body.

Genus XLV. Hypochondriasis. Dyspepsia, with languor, sadness, and fear, without any adequate causes, in a melancholy temperament.

Genus XLVI. Chlorosis. Dyspepsia, or a desire of something not used as food; a pale or discolored complexion; the veins not well filled: a soft tumor of the whole body; asthenia; palpitation; suppression of the menses.

Order III. SPASMI. Irregular motions of the muscles or muscular fibres.

Sect. I. *In the animal functions.*

Genus XLVII. Tetanus. A spastic rigidity of almost the whole body.

Varying according to the remote cause, as it rises either from something internal, from cold, or from a wound. It varies likewise, from whatever cause it may arise, according to the part of the body affected.

Genus XLVIII. Trismus. A spastic rigidity of the lower jaw. The species are,

1. Trismus (nascentium), attacking infants under two months old.

2. Trismus (traumaticus), attacking people of all ages, either from a wound or cold.

Genus XLIX. Convulsio. An irregular clonic contraction of the muscles without sleep.

I. Idiopathic.

II. Symptomatic.

Genus L. Chorea, attacking those who have not yet arrived at puberty, most commonly within the tenth or fourteenth year, with convulsive motions for the most part of one side in attempting the voluntary motion of the hands and arms, resembling the gesticulations of mountebanks; in walking, rather dragging one of their feet than lifting it.

Genus LI. Raphania. A spastic contraction of the joints, with a convulsive agitation, and most violent periodical pain.

Genus LII. Epilepsia. A convulsion of the muscles, with sleep.

The idiopathic species are,

1. Epilepsia (cerebralis), suddenly attacking without any manifest cause, without any sense of uneasiness preceding, excepting perhaps a slight vertigo or dimness of sight.

2. Epilepsia (sympathica), without any manifest cause, but preceded by the sensation of a kind of air rising from a certain part of the body towards the head.

3. Epilepsia (occasionalis), arising from a manifest irritation, and ceasing on the removal of that irritation.

Varying according to the difference of the irritating matter. And thus it may arise,

From injuries of the head, pain, worms, poison; from the repulsion of the itch, or an effusion of any other acrid humor; from crudities in the stomach; from passions of the mind; from an immoderate hæmorrhagy, or from debility.

Sect. II. *In the vital functions.*

In the action of the heart.

Genus LIII. Palpitatio. A violent and irregular motion of the heart.

In the action of the lungs.

Genus LIV. Asthma. A difficulty of breathing returning by intervals, with a sense of straitness in the breast, and a noisy respiration with hissing. In the beginning of the paroxysm there is either no cough at all, or coughing is difficult; but, towards the end, the coughing becomes free, frequently with a copious spitting of mucus. The idiopathic species are,

1. Asthma (spontaneum), without any manifest cause or other concomitant disease.

2. Asthma (exanthematicum), from the repulsion of the itch or other acrid effusion.

3. Asthma (plethoricum), from the suppression of some customary sanguineous evacuation, or from a spontaneous plethora.

Genus LV. Dyspnœa. A continual difficulty of breathing, without any sense of straitness, but rather of fullness and infarction in the breast; a frequent cough throughout the whole course of the disease.

The idiopathic species are,

1. Dyspnœa (catarrhalis), with a frequent cough, bringing up plenty of viscid mucus.

2. Dyspnœa (sicca), with a cough for the most part dry.

3. Dyspnœa (aërea), increased by the least change of weather.

4 Dyspnœa (terrea), bringing up with the cough an earthy or calculous matter.

5. Dyspnœa (aquosa), with scanty urine and œdematous feet; without any fluctuation in the breast, or other signs of an hydrothorax.

6. Dyspnœa (pinguedinosa), in very fat people.

7. Dyspnœa (thoracica), from an injury done to the parts surrounding the thorax, or from some malconformation of them.

8. Dyspnœa (extrinseca), from evident external causes.

The symptomatic species of dyspnœa are consequences,

1. Of diseases of the heart or large vessels.

2. Of a swelling in the abdomen.

3. Of various other diseases.

Genus LVI. Pertussis. A contagious disease; convulsive strangulating cough reiterated with noisy inspiration; frequent vomiting.

Sect. III. *In the natural functions.*

Genus LVII. Pyrosis. A burning pain in the epigastrium, with plenty of aqueous humor, for the most part insipid, but sometimes acrid, belched up.

Genus LVIII. Colica. Pain of the belly, especially twisting round the navel; vomiting; and a constipation.

The idiopathic species are,

1. Colica (spasmodica), with retraction of the navel, and spasms of the abdominal muscles.

Varying, by reason of some symptoms superadded. Hence,

a, Colica, with vomiting of excrements, or of matters injected by the anus.

b, Colica, with inflammation supervening.

2. Colica (pictonum), preceded by a sense of weight or uneasiness in the belly, especially about the navel; then comes on the colic pain, at first slight and interrupted, chiefly augmented after meals; at length more severe and almost continual, with pains of the arms and back; at last ending in a palsy.

Varying according to the nature of the remote cause; and hence,

a, From metallic poison.

b, From acids taken inwardly.

c, From cold.

d, From a contusion of the back.

3. Colica (stercorea), in people subject to costiveness.

4. Colica (accidentalis), from acrid matter taken inwardly.

5. Colica (meconialis), in new-born children from a retention of the meconium.

6. Colica (callosa), with a sensation of stricture in some part of the intestines, and frequently of a collection of flatus with some pain: which flatus also passing through the part where the stricture is felt, gradually vanishes; the belly slow, and at last passing only a few liquid fæces.

7. Colica (calculosa), with a fixed hardness in some part of the abdomen, and calculi sometimes passed by the anus.

Genus LIX. Cholera. A vomiting of bilious matter, and likewise a frequent excretion of the same by stool; anxiety; gripes; spasms in the calves of the legs.

I. Idiopathic.

1. Cholera (spontanea), arising in a warm season, without any manifest cause.

2. Cholera (accidentalis), from acrid matters taken inwardly.

II. Symptomatic.

Genus LX. Diarrhœa. Frequent stools; the disease not infectious; no primary pyrexia.

I. Idiopathic.

1. Diarrhœa (crapulosa), in which the excrements are voided in greater quantity than naturally.

2. Diarrhœa (biliosa), in which yellow fæces are voided in great quantity.

3. Diarrhœa (mucosa) in which either from acrid substances taken inwardly, or from cold, especially applied to the feet, a great quantity of mucus is voided.

4. Diarrhœa (cœliaca), in which a milky humor of the nature of chyle is discharged by stool.

5. Diarrhœa (lienteria), in which the aliments are discharged with little alteration soon after eating.

6. Diarrhœa (hepatirrhœa), in which a bloody serous matter is discharged without pain.

II. Symptomatic.

Genus LXI. Diabetes. A chronical profusion of urine, for the most part preternatural, and in immoderate quantity.

I. Idiopathic.

1. Diabetes (mellitus), with urine of the smell, color, and taste of honey.

2. Diabetes (insipidus), with limpid, but not sweet, urine.

II. Symptomatic.

Genus LXII. Hysteria. Rumbling of the bowels; a sensation as of a globe turning itself in the belly, ascending to the stomach and fauces, and there threatening suffocation; sleep; convulsions; a great quantity of limpid urine; the mind involuntarily fickle and mutable.

The following are by Sauvages reckoned distinct idiopathic species; but by Dr. Cullen only varieties of the same species

A, From a retention of the menses.

B, From a menorrhagia cruenta.

C, From a menorrhagia serosa, or fluor albus.

D, From an obstruction of the viscera.

E, From a fault of the stomach.

F, From too great salacity.

Genus LXIII. Hydrophobia. A dislike and horror at any kind of drink, as occasioning a convulsion of the pharynx; induced for the most part by the bite of a mad animal. The species are,

1. Hydrophobia (rabiosa), with a desire of biting the bystanders, occasioned by the bite of a rabid animal.

II. Hydrophobia (simplex), without madness, or any desire of biting

Order IV. Vesaniæ. Disorders of the judgment, without any pyrexia or coma.

Genus LXIV. Amentia; an imbecility of judgment, by which people either do not perceive, or do not remember, the relations of things. The species are,

I. Amentia (congenita), continuing from birth.

II. Amentia (senilis), from the diminution of the perceptions and memory through extreme old

III. Amentia (acquisita), occurring in people formerly of a sound mind, from evident external causes.

Genus LXV. Melancholia; a partial madness, without dyspepsia.

Varying according to the different subjects concerning which the person raves; and thus it is,

1. With an imagination in the patient concerning his body being in a dangerous condition, from slight causes; or his affairs in a desperate state.

2. With an imagination concerning a prosperous state of affairs.

3. With violent love, without satyriasis or nymphomania.

4. With a superstitious fear of a future state.

5. With an aversion from motion and all the offices of life.

6. With restlessness, and an impatience of any situation whatever.

7. With a weariness of life.

1. With a deception concerning the nature of the patient's species,

Dr. Cullen thinks that there is no such disease as that called dæmonomania, and that the diseases mentioned by Sauvages under that title are either,

1. Species of melancholy or mania; or

2. Of some disease by the spectators falsely ascribed to the influence of an evil spirit; or

3. Of a disease entirely feigned; or

4. Of a disease partly true and partly feigned.

Genus LXVI. Mania; universal madness.

1. Mania (mentalis), arising entirely from passions of the mind.

2. Mania (corporea), from an evident disease of the body.

Varying according to the different disease of the body.

3. Mania (obscura), without any passion of mind or evident disease of the body preceding.

The symptomatic species of mania are,

1. Paraphrosyne from poisons.

2. Paraphrosyne from passion.

3. Paraphrosyne febrilis.

Genus LXVII. Oneirodynia. A violent and troublesome imagination in time of sleep.

1. Oneirodynia (activa), exciting to walking and various motions.

2. Oneirodynia (gravans), from a sense of some weight incumbent, and pressing on the breast especially.

Class III. CACHEXIÆ; a depraved habit of the whole or greatest part of the body, without primary pyrexia or neurosis.

Order I. Marcores; emaciation of the whole body.

Genus LXVIII. Tabes. Leanness, asthenia, hectic fever. The species are,

1. Tabes (purulenta), from an external or internal ulcer, or from a vomica.

Varying in its situation; hence,

2. Tabes (scrofulosa), in scrofulous constitutions.

3. Tabes (venenata), from poison taken inwardly.

Genus LXIX. Atrophia. Leanness and asthenia, without hectic fever The species are,

1. Atrophia (inanitorum), from too great evacuation.

2. Atrophia (famelicorum), from a want of nourishment.

3. Atrophia (cacochymica), from corrupted nourishment.

4. Atrophia (debilium), from the function of nutrition being depraved, without any extraordinary evacuation or cacochymia having preceded.

Order II. Intumescentiæ. An external swelling of the whole or greatest part of the body.

Sect. I. *Adiposæ*.

Genus LXX. Polysarcia; a troublesome swelling of the body from fat.

Sect. II. *Flatuosæ*.

Genus LXXI. Pneumatosis; a tense elastic swelling of the body, crackling under the hand The species are,

1. Pneumatosis (spontanea), without any manifest cause.

2. Pneumatosis (traumatica), from a wound in the breast.

3. Pneumatosis (veneneta), from poison injected or applied.

4. Pneumatosis (hysterica), with hysteria.

Genus LXXII. Tympanites; a tense, elastic, sonorous swelling of the abdomen; costiveness; a decay of the other parts. The species are,

1. Tympanites (intestinalis), with a tumor of the abdomen frequently unequal, and with a frequent evacuation of air relieving the tension and pain.

2. Tympanites (abdominalis) with a more evident noise, a more equable tumor, and a less frequent emission of flatus, which also gives less relief.

Genus LXXIII. Physometra; a slight elastic swelling in the epigastrium, having the figure and situation of the uterus.

Sect. III. *Aquosæ* or *Dropsies*.

Genus LXXIV. Anasarca. A soft, inelastic swelling of the whole body, or some part of it. The species are,

1. Anasarca (serosa), from a retention of serum on account of the suppression of the usual evacuations, or from an increase of the serum on account of too great a quantity of water taken inwardly.

2. Anasarca (oppilata), from a compression of the veins.

3. Anasarca (exanthematica), arising after exanthemata, especially succeeding erysipelas.

4. Anasarca (anæmia), from the thinness of the blood produced by hæmorrhagy.

5. Anasarca (debilium), in weak people after long diseases, or from other causes.

Genus LXXV. Hydrocephalus. A soft inelastic swelling of the head, with the sutures of the cranium opened.

Genus LXXVI. Hydrorachitis. A soft, slender tumor above the vertebræ of the loins; the vertebræ gaping from each other.

Genus LXXVII. Hydrothorax. Dyspnœa; paleness of the face; œdematous swellings of the feet; scanty urine; difficult lying in a recumbent posture; a sudden and spontaneous starting out of sleep, with palpitation; water fluctuating in the breast.

Genus LXXVIII. Ascites. A tense, scarce elastic, but fluctuating swelling of the abdomen. The species are,

1. Ascites (abdominalis), with an equal swelling of the whole abdomen, and with a fluctuation sufficiently evident.

Varying according to the cause.

A, From an obstruction of the viscera.

B, From debility.

C, From a thinness of the blood.

2. Ascites (saccatus), with a swelling of the abdomen, in the beginning at least, partial, and with a less evident fluctuation.

Genus LXXIX. Hydrometra. A swelling of the hypogastrium in women, gradually increasing, keeping the shape of the utorus, yielding to pressure, and fluctuating; without ischuria or pregnancy.

Genus LXXX. Hydrocele. A swelling of the scrotum, not painful; increasing by degrees, soft, fluctuating, and pellucid.

Sect. IV. *Solidæ*.

Genus LXXXI. Physconia. A swelling chiefly occupying a certain part of the abdomen, gradually increasing, and neither sonorous nor fluctuating. The species are

Physconia hepatica.
Physconia splenica.
Physconia renalis.
Physconia uterina.
Physconia ab ovario.
Physconia mesenterica.
Physconia intestinalis.
Physconia omentalis.
Physconia polysplachna.
Physconia visceralis.
Physconia externa lupialis.
Physconia externa schirrhodea.
Physconia externa hydatidosa.
Physconia ab adipe subcutaneo.
Physconia ab excrescentia.

Genus LXXXII. Rachitis. A large head swelling most in the fore part, the ribs depressed, abdomen swelled, with a decay of the other parts.

Varying,

1. Simple, without any other disease.

2. Joined with other diseases.

Order III. Impetigines. Cachexies chiefly deforming the skin and external parts of the body.

Genus LXXXIII. Scrofula. Swellings of the conglobate glands, especially in the neck: swelling of the upper lip and of the nose; the face florid, skin thin, abdomen swelled. The species are,

1. Scrofula (vulgaris), simple, external, and permanent.

2. Scrofula (mesenterica), simple, internal, with paleness of the face, want of appetite, swelling of the abdomen, and unusual fetor of the excrements.

3. Scrofula (fugax), most simple, appearing only about the neck; for the most part proceeding from the resorption of the matter of ulcers in the head.

4. Scrofula (Americana), joined with the yaws.

Genus LXXXIV. Syphilis. A contagious disease; ulcers of the tonsils, after impure venery, and a disorder of the genitals; clustered

pimples of the skin, especially about the margin of the hair, ending in crusts and crusty ulcers; pains of the bones; exostoses.

Genus LXXXV. Scorbutus; in cold countries attacking after putrescent diet, especially such as is salt and of the animal kind, where no supply of fresh vegetables is to be had; asthenia; stomacace; spots of different colors on the skin, for the most part livid, and appearing chiefly among the roots of the hair.

Varying in degree.

a, Scorbutus incipiens.

b, Scorbutus crescens.

c, Scorbutus inveteratus.

Varying also in symptoms.

d, Scorbutus lividus.

e, Scorbutus petechialis.

f, Scorbutus pallidus.

g, Scorbutus ruber.

h, Scorbutus calidus.

Genus LXXXVI. Elephantiasis; a contagious disease: thick, wrinkled, rough, unctuous skin, destitute of hairs, anæsthesia in the extremities, the face deformed with pimples, the voice hoarse and nasal.

Genus LXXXVII. Lepra; the skin rough, with white, branny, and chopped eschars, sometimes moist beneath, with itching.

Genus LXXXVIII. Frambœsia; swellings resembling fungi, or the fruit of the mulberry or raspberry, growing on various parts of the skin.

Genus LXXXIX. Trichoma; a contagious disease; the hairs thicker than usual, and twisted into inextricable knots and cords.

Genus XC. Icterus; yellowness of the skin and eyes; white fæces; urine of a dark red, tinging what is put into it of a yellow color.

The idiopathic species are,

1. Icterus (calculosus), with acute pain in the epigastric region, increasing after meals; biliary concretions voided by stool.

2. Icterus (spasmodicus), without pain after spasmodic diseases and passions of the mind.

3. Icterus (hepaticus), without pain, after diseases of the liver.

4. Icterus (gravidarum), arising during the time of pregnancy, and going off after delivery.

5. Icterus (infantum), coming on in infants a few days after birth.

Class IV. LOCALES. An affection of some part, but not of the whole body.

Order I. Dysæsthesiæ. The senses depraved or destroyed, from a disease of the external organs.

Genus XCI. Caligo. The sight impaired or totally destroyed, on account of some opaque substance interposed between the objects and the retina, inherent in the eye itself or the eyelids. The species are,

1. Caligo (lentis), occasioned by an opaque spot behind the pupil.

2. Caligo (corneæ), from an opacity of the cornea.

3. Caligo (pupillæ), from an obstruction of the pupil.

Varying according to the different causes from which it proceeds.

4. Caligo (humorum), from a disease or defect of the aqueous humor.

Varying according to the different state of the humor.

5. Caligo (palpebrarum) from a disease inherent in the eyelids.

Varying according to the nature of the disease in the eyelids.

Genus XCII. Amaurosis. The sight diminished, or totally abolished, without any evident disease of the eye; the pupil for the most part remaining dilated and immoveable. The species are,

1. Amaurosis (compressionis), after the causes and attended with the symptoms of congestion in the brain.

Varying according to the nature of the remote cause.

2. Amaurosis (atonica), after the causes and accompanied with symptoms of debility.

3. Amaurosis (spasmodica), after the causes and with the signs of spasm.

4. Amaurosis (venenata), from poison taken into the body or applied outwardly to it.

Genus XCIII. Dysopia. A depravation of the sight, so that objects cannot be distinctly perceived, except at a certain distance, and in a certain situation.

The species are,

1. Dysopia (tenebrarum), in which objects are not seen unless they be placed in a strong light.

2. Dysopia (luminis), in which objects are not distinctly seen unless by a weak light.

3. Dysopia (dissitorum), in which distinct objects are not perceived.

4. Dysopia (proximorum), in which the nearest objects are not perceived.

5. Dysopia (lateralis), in which objects are not perceived unless placed in an oblique posture.

Genus XCIV. Pseudoblepsis; when the sight is diseased in such a manner that the person imagines he sees things which really do not exist, or sees things which do exist after some other manner than they really are. The species are,

1. Pseudoblepsis (imaginaria), in which the person imagines he sees things which really do not exist.

Varying according to the nature of the imagination.

2. Pseudoblepsis (mutans), in which objects really existing appear somehow changed.

Varying according to the change perceived in the objects, and according to the remote cause.

Genus XCV. Dysecœa. A diminution or total abolition of the sense of hearing. The species are,

1. Dysecœa (organica), from a disease in the organs transmitting sounds to the internal ear.

Varying according to the nature of the disease and of the part affected.

2. Dysecœa (atonica), without any evident disease of the organs transmitting the sounds.

Varying according to the nature of the cause.

Genus XCVI. Paracusis: a depravation of the hearing. The species are,

1. Paracusis (imperfecta), in which, though sounds coming from external objects are heard, yet it is neither distinctly nor in the usual manner.

Varying,

a, With a dulness of hearing.

b, With a hearing too acute and sensible.

c, When a single external sound is doubled by some internal causes.

d, When the sounds which a person desires to hear are not perceived, unless some other violent sound is raised at the same time.

2. Paracusis (imaginaria), in which sounds not existing externally are excited from internal causes.

Varying according to the nature of the sound perceived, and according to the nature of the remote cause.

Genus XCVII. Anosmia; a diminution or abolition of the sense of smell. The species are,

1. Anosmia (organica), from a disease in the membrane lining the internal parts of the nostrils.

Varying according to the nature of the disease.

2. Anosmia (atonica), without any evident disease of the membrane of the nose.

Genus XCVIII. Agheustia; a diminution or abolition of the sense of taste.

1. Agheustia (organica), from a disease in the membrane of the tongue, keeping off from the nerves those substances which ought to produce taste.

2. Agheustia (atonica), without any evident disease of the tongue.

Genus XCIX. Anæsthesia; a diminution or abolition of the sense of feeling. The species from Sauvages, adopted by Dr. Cullen, are,

1. Anæsthesia à spina bifida.
2. Anæsthesia plethorica.
3. Anæsthesia nascentium.
4. Anæsthesia melancholica.

Order II. Dysorexiæ; error or defect of appetite.

Sect. I. *Appetitus erronei.*

Genus C. Bulimia; a desire for food in greater quantities than can be digested.

The idiopathic species are,

1. Bulimia (helluonum), an unusual appetite for food, without any disease of the stomach.

2. Bulimia (syncopalis), a frequent desire of meat, on account of a sensation of hunger threatening syncope.

3. Bulimia (emetica), an appetite for a great quantity of meat, which is thrown up immediately after it is taken.

Genus CI. Polydipsia; an appetite for an unusual quantity of drink.

The polydipsia is almost always symptomatic, and varies only according to the nature of the disease which accompanies it.

Genus CII. Pica; a desire of swallowing substances not used as food.

Genus CIII. Satyriasis; an unbounded desire of venery in men. The species are,

1. Satyriasis (juvenilis), an unbounded desire of venery, the body at the same time being little disordered.

2. Satyriasis (furens), a vehement desire of venery with a great disorder of the body at the same time.

Genus CIV. Nymphomania; an unbounded desire of venery in women.

Varying in degree.

Genus CV. Nostalgia; a violent desire of those who are absent from their country of revisiting it.

1. Nostalgia (simplex), without any other disease.

2. Nostalgia (complicata), accompanied with other diseases.

Sect. II. *Appetitus deficientes.*

Genus CVI. Anorexia. Want of appetite for food. Always symptomatic.

1. Anorexia (humoralis), from some humor loading the stomach.

2. Anorexia (atonica), from the tone of the fibres of the stomach being lost.

Genus CVII. Adipsia; a want of desire for drink. Always a symptom of some disease affecting the sensorium commune.

Genus CVIII. Anaphrodisia; want of desire for, or impotence to, venery.

The true species are,

1. Anaphrodisia paralytica.
2. Anaphrodisia gonorrhoica.

The false ones are,

1. Anaphrodisia à mariscis.
2. Anaphrodisia ab urethræ vitio.

Order III. Dyscinesiæ. An impediment, or depravation of motion from a disorder of the organs.

Genus CIX. Aphonia; a total suppression of voice without coma or syncope. The species are,

1. Aphonia (gutturalis), from the fauces or glottis being swelled.

2. Aphonia (trachealis), from a compression of the trachea.

3. Aphonia (atonica), from the nerves of the larynx being cut.

Genus CX. Mutitas; a want of power to pronounce words. The species are,

1. Mutitas (organica), from the tongue being cut out or destroyed.

2. Mutitas (atonica), from injuries done to the nerves of the tongue.

3. Mutitas (surdorum), from people being born deaf, or the hearing being destroyed during childhood.

Genus CXI. Paraphonia; a depraved sound of the voice. The species are,

1. Paraphonia (puberum), in which, about the time of puberty, the voice from being acute and sweet, becomes more grave and harsh.

2. Paraphonia (rauca), in which, by reason of the dryness or flaccid tumor of the fauces, the voice becomes rough and hoarse.

3. Paraphonia (resonans), in which, by reason of an obstruction of the nostrils, the voice becomes hoarse, with a sound hissing through the nostrils.

4. Paraphonia (palatina), in which, on account of a defect or division of the uvula, for the most part with a hare-lip, the voice becomes obscure, hoarse, and unpleasant.

5. Paraphonia (clangens), in which the voice is changed to one acute, shrill, and small.

6. Paraphonia (comatosa), in which, from a relaxation of the velum palati and glottis, a sound is produced during inspiration.

Genus CXII. Psellismus; a defect in the articulation of words. The species are,

1. Psellismus (hæsitans), in which the words, especially the first ones of a discourse, are not easily pronounced, and not without a frequent repetition of the first syllable.

2. Psellismus (ringens), in which the sound of the letter R is always aspirated, and, as it were, doubled.

3. Psellismus (lallans), in which the sound of the letter L becomes more liquid, or is pronounced instead of R.

4. Psellismus (emolliens), in which the hard letters are changed into the softer ones, and thus the letter S is much used.

5. Psellismus (balbutiens), in which, by reason of the tongue being large, or swelled, the labial letters are better heard, and often pronounced instead of others.

6. Psellismus (acheilos), in which the labial letters cannot be pronounced at all, or with difficulty.

7. Psellismus (lagostomatum), in which, on account of the division of the palate, the guttural letters are less perfectly pronounced.

Genus CXIII. Strabismus; the optic axes of the eyes not converging. The species are,

1. Strabismus (habitualis), from a bad custom of using only one eye.

2. Strabismus (commodus), from the greater debility or mobility of one eye above the other; so that both eyes cannot be conveniently used.

3. Strabismus (necessarius), from a change in the situation or shape of the parts of the eye.

Genus CXIV. Dysphagia; impeded deglutition, without phlegmasia, or the respiration being affected.

Genus CXV. Contractura; a long-continued and rigid contraction of one or more limbs. The species are,

1. Contractura (primaria), from the muscles becoming contracted and rigid.

a, From the muscles becoming rigid by inflammation.

b, From muscles becoming rigid by spasm.

c, From muscles contracted by reason of their antagonists having become paralytic.

d, From muscles contracted by an irritating acrimony.

2. Contractura (articularis), from stiff joints.

Order IV. Apocenosis. A flux either of blood or some other humor flowing more plentifully than usual, without pyrexia, or an increased impulse of fluids.

Genus CXVI. Profusio; a flux of blood.

Genus CXVII. Ephidrosis; a preternatural evacuation of sweat.

Symptomatic ephidroses vary according to the nature of the diseases which they accompany, the different nature of the sweat itself, and sometimes the different parts of the body which sweat most.

Genus CXVIII. Epiphora; a flux of the lachrymal humor.

Genus CXIX. Ptyalismus; a flux of saliva.

Genus CXX. Enuresis; an involuntary flux of urine without pain. The species are,

1. Enuresis (atonica), after diseases injuring the sphincter of the bladder.

2. Enuresis (irritata), from a compression or irritation of the bladder.

Genus CXXI. Gonorrhœa; a preternatural flux of humor from the urethra in men, with or without a desire of venery. The species are,

1. Gonorrhœa (pura), in which, without any impure venery having preceded, a fluid resembling pus, without dysuria or propensity to venery, flows from the urethra.

2. Gonorrhœa (impura), in which, after impure vereny, a fluid like pus flows from the urethra with dysuria. The consequence of this is,

Gonorrhœa (mucosa), in which, after an impure gonorrhœa, a mucous humor flows from the urethra with little or no dysuria.

3. Gonorrhœa (laxorum), in which a humor for the most part pellucid, without any erection of the penis, but with a propensity to venery, flows from the urethra while the person is awake.

4. Gonorrhœa (dormientium), in which the seminal liquor is thrown out, with erection and desire of venery, in those who are asleep and have lascivious dreams.

Order V. Epischeses; suppressions of evacuations.

Genus CXXII. Obstipatio; the stools either suppressed, or slower than usual. The species are,

1. Obstipatio (debilium), in lax, weak, and for the most part dyspeptic persons.

2. Obstipatio (rigidorum), in people whose fibres are rigid, and frequently of an hypochondriac disposition.

3. Obstipatio (obstructorum), with symptoms of the colica 1st, 2d, 4th, and 7th above-mentioned.

Genus CXXIII. Ischuria; an absolute suppression of urine. The species are,

1. Ischuria (renalis), coming after a disease of the kidneys, with pain, or troublesome sense of weight in the region of the kidneys, and without any swelling of the hypogastrium, or desire of making water.

2. Ischuria (ureterica), coming after a disease of the kidneys, with a sense of pain or uneasiness in some part of the ureter, and without any tumor of the hypogastrium, or desire of making water.

3. Ischuria (vesicalis), with a swelling of the hypogastrium, pain at the neck of the bladder, and a frequent stimulus to make water.

4. Ischuria (urethralis), with a swelling of the hypogastrium, frequent stimulus to make water, and pain in some part of the urethra.

All these species are subdivided into many varieties, according to their different causes.

Genus CXXIV. Dysuria; a painful and somehow impeded emission of urine. The species are,

1. Dysuria (ardens), with heat of urine, without any manifest disorder of the bladder.

2. Dysuria (spasmodica), from a spasm communicated from the other parts to the bladder.

3. Dysuria (compressionis), from the neighbouring parts pressing upon the bladder.

4. Dysuria (phlogistica), from an inflammation of the neighbouring parts.

5. Dysuria (irritata), with signs of a stone in the bladder.

6. Dysuria (mucosa), with a copious excretion of mucus.

Genus CXXV. Dyspermatismus; a slow, impeded, and insufficient emission of semen in the venereal act. The species are,

1. Dyspermatismus (urethralis), from diseases of the urethra.

2. Dyspermatismus (nodosus), from knots on the corpora cavernosa penis.

3. Dyspermatismus (præputialis), from too narrow an orifice of the prepuce.

4. Dyspermatismus (mucosus), from mucus infarcting the urethra.

5. Dyspermatismus (hypertonicus), from too strong an erection of the penis.

6. Dyspermatismus (epilepticus), from a spasmodic epilepsy happening during the time of coition.

7. Dyspermatismus (apractodes), from an imbecility of the parts of generation.

8. Dyspermatismus (refluus), in which there is no emission of semen, because it returns from the urethra into the bladder.

Genus CXXVI. Amenorrhœa. The menses either flowing more sparingly than usual, or not at all, at their usual time, without pregnancy. The species are,

1. Amenorrhœa (emansionis), in those arrived at puberty, in whom, after the usual time, the menses have not yet made their appearance, and many different morbid affections have taken place.

2. Amenorrhœa (suppressionis), in adults, in whom the menses which had already begun to flow are suppressed.

3. Amenorrhœa (difficilis), in which the menses flow sparingly, and with difficulty.

Order VI. Tumores; an increased magnitude of any part without phlogosis.

Genus CXXVII. Aneurisma; a soft tumor, with pulsation, above an artery.

Genus CXXVIII. Varix; a soft tumor, without pulsation, above a vein.

Genus CXXIX. Ecchymoma; a diffused, little eminent, and livid tumor.

Genus CXXX. Schirrus; a hard tumor of some part, generally of a gland, without pain, and difficultly brought to suppuration.

Genus CXXXI. Cancer; a painful tumor of a schirrous nature, and degenerating into an ill-conditioned ulcer.

Genus CXXXII. Bubo; a suppurating tumor of a conglobate gland.

Genus CXXXIII. Sarcoma; a soft swelling, without pain.

Genus CXXXIV. Verruca; a harder scabrous swelling.

Genus CXXXV. Clavus; a hard, lamellated thickness of the skin.

Genus CXXXVI. Lupia; a moveable, soft tumor below the skin, without pain.

Genus CXXXVII Ganglion; a hard moveable swelling, adhering to a tendon.

Genus CXXXVIII. Hydatis; a cuticular vesicle filled with aqueous humor.

Genus CXXXIX. Hydarthrus; a most painful swelling of the joints, chiefly of the knee, at first scarcely elevated, of the same color with the skin, diminishing the mobility.

Genus CXL. Exostosis; a hard tumor adhering to a bone.

Order VII. Ectopiæ; tumors occasioned by the removal of some part out of its proper situation.

Genus CXLI. Hernia; an ectopia of a soft part as yet covered with skin and integuments.

Genus CXLII. Prolapsus; a bare ectopia of some soft part.

Genus CXLIII. Luxatio; the removal of a bone from its place in the joints.

Order VIII. Dialyses. A solution of continuity; manifest to the sight or touch.

Genus CXLIV. Vulnus; a recent and bloody solution of the unity of some soft part by the motion of some hard body.

Genus CXLV. Ulcus. A purulent or ichorous solution of a soft part.

Genus CXLVI. Herpes; a great number of phlyctenæ or small ulcers, gathering in clusters, creeping, and obstinate.

Genus CXLVII. Tinea; small ulcers among the roots of the hair of the head, pouring out a fluid which changes to a white friable scurf.

Genus CXLVIII. Psora. Itchy pustules and little ulcers of an infectious nature, chiefly infecting the hands.

Genus CXLIX. Fractura; bones broken into large fragments.

Genus CL. Caries; an ulceration of a bone.

PART III.

THEORY OF MEDICINE.

Having thus laid before the reader the scheme of arrangement which, for the reasons above named, we adopt for our guide on the present occasion, we shall now proceed to a slight disquisition on the theoretical part of medicine, prior to engaging in the consideration of morbid affections, separately and particularly. It is usual for authors on medicine to engage in topics of physiological bearing when treating on theory—indeed physiology constitutes a great part of medical theory—and we take the opportunity of saying that Dr. Mason Good has much enriched his volumes, published under the title of The Study of Medicine, in preliminary chapters to his pathological and therapeutic disquisitions, with a most interesting sketch of the physiology of all the functions.

In the present case, however, we shall not include physiology, as that science will fall to be treated of in a separate article, but shall limit ourselves to pathological principles; and, in so doing, we propose to avail ourselves of the proem prefixed by Dr. Uwins to his Compendium of Theoretical and Practical Medicine, this author having given a running commentary, which we are about to follow, on the classes and orders of Cullen's Nosology. Dr. U. has likewise engaged in physiological considerations; but, for the reasons just stated, we shall at present pass over these points.

265. In the first class of Cullen's arrangement, which the reader will recollect is entitled Pyrexiæ, are comprehended the five following orders—fevers, inflammations, eruptive disorders of an acute kind, hæmorrhages, and fluxes; and, as we slightly go over the pathology of the circulating organs, or, in other words, the theory of their derangement, each of the above kinds of morbid being will fall under our notice.

266. Pyrexia implies an increase of the body's heat, and it behoves us to enquire in what way this is brought about; but the enquiry is attended with many difficulties, inasmuch as the mode in which the natural heat of the frame is maintained is still a matter of some obscurity. 'When the chemical changes that take place during respiration had been enquired into, and when it was found that the capacity of carbonic acid for heat was less than that of oxygen, it was supposed that the conversion of oxygen into carbonic acid gas was the cause of the rise of temperature; and, as the heat of the lungs does not exceed that of other parts, it was asserted that the air was absorbed by the blood, and that the production of carbonic acid, and consequent evolution of heat, took place gradually during the circulation.' To these opinions many strong objections have, from time to time, been urged by different physiologists, but their complete subversion followed the researches of Mr. Brodie (Phil. Trans. 1812), who found that the heart was capable of retaining its functions for some hours, and of carrying on circulation in a decapitated animal, and consequently independent of the influence of the brain, when respiration was artificially carried on. Under these circumstances it was observed, that, although the change of blood from the venous to the arterial state was perfect, no heat was generated, and that the animal cooled regularly and gradually down to the atmospheric standard. In more than one instance the expired air was examined, and found to contain as much carbonic acid as was produced by the healthy animal; so that here circulation went on, there was the change of oxygen into carbonic acid, and the alteration of color in the blood, and yet no heat whatever appeared to be generated.

267. Since then, even on the subject of vital temperature, without reference to disease, much remains to be explained, and some positions have been assumed which experiment proves to be untenable, it follows, that to account for the increase of heat as health recedes must be a task of much difficulty; and perhaps very little more at present is known on this point than that an increase of exterior and internal heat accompanies the excitation of certain superficial or interior movements. Indeed, heat from motion, and cold from quiescence, are, with some modification, laws of inorganic matter; so much so, that some philosophers have considered the introduction of a subtile material, as the essence of heat, to be not only gratuitous but unnecessary, and have maintained that heat, like every other incident of bodies, is but a manifestation of altered form or circumstance of the body; and, although inorganic and organised being are regulated by different laws, we see and know enough of the latter to be convinced that action and heat are in some measure connected even in it, in the way of cause and effect. But let us, dismissing the intricate topic of natural and morbid heat, as excited and maintained in an organised body, say a few words in succession on the several disordered conditions above enumerated, viz. fever, inflammation, eruptive affection, hæmorrhage, and flux. The order, however, of the two first, for reasons which will soon be obvious, we shall reverse, and treat, in the first place, on inflammation.

268. When treating on the circulation, in the article PHYSIOLOGY, we shall have to state that one of the arguments adduced in favor of an independent power in the arterial system—that is of a power independent of the motive power of the heart—is taken from the circumstance that partial distribution of blood may have place without, in the first instance at least, the heart itself being changed from its steady course of regular procedure. Thus, in a given spot, an increased quantum and momentum of blood shall be discoverable; this augmented momentum and excitement shall bring with them an increase of heat, and eventually all the phenomena shall manifest themselves to which the term inflammation would be applied, merely from topical or local causes, the heart and other parts of the vascular organisation only then coming to be affected when the commotion shall have excited what are called sympathetic or secondary considerations. But inordinate action, and consequent heat, do not of themselves constitute inflammation. Of what then is inflammation actually formed? We may suppose the eye to be suddenly and unexpectedly subjected to an undue quantity of light; inordinate excitation is the immediate consequence, in other words the fibres of which the organ is composed are for a time irritated into more vigorous movement than is ordinarily the case; the volume and force of its circulation are rendered more abundant, and visual perception is in the same ratio increased. All this however may exist without the presence of positive inflammation; we have here augmented, but not otherwise deranged action—the error loci of the schools has not taken place; the component parts of the blood preserve their proportionate relations, and the ordinary standard of circulating power is shortly restored without the intervention of organic derangement.

269. But let the stimulus be applied with more force, or let it be brought to act under greater than usual irritability of the organ, a different state of things will soon commence; the blood vessels, which are usually colorless, will now be seen to convey red blood, new secretions will take place, and in the course of a short time new parts or vessels will be actually formed. If, then, we are asked for a definition of the inflamed state, as opposed to mere excitation or fulness of vessel, we reply that it is such excitation or such plenitude carried up to the extent of actual derangement; the capillaries do not merely momentarily receive, but positively and permanently circulate an unhealthy quantity of blood; while this break-in upon her orderly course nature will not permit, without setting about the work of regeneration in order to be ready, as it were, for the breach that is about to be made.

270. Actual inflammation, then, seems to a certain extent to be disorganisation, and this disorganisation implies a weakened state of the capillary or smaller vessels, either forcibly, induced by the rush of blood into them when the inflammation has been more active, or sthenic,

as some pathologists would call it, or more passively brought about when the impetus has not been much above its common grade, but when from some circumstances of obstraction, or other accidental conditions, the capillaries are made to receive and transmit such a quantity of blood as to distend them and excite them into perturbed motions; for in either case undue action and irritation seem necessary to the formation of the inflammatory state, otherwise the state would be that of mere fulness or congestion.

271. Why in case either of more active or passive inflammation, says the author whom we are now following, there should be the resisting and repairing actions set up which have been above adverted to, there is no possibility of explaining beyond an appeal to final cause, and this Deus intersit language ought never to be introduced when the subject is not morals nor religion but physiology and physics. What, it has been justly remarked, does John Hunter's 'stimulus of necessity' amount to, as applied to the blood's coagulation, more than that the blood coagulates because it must coagulate?

272. 'If there be any correctness', he continues,' 'in what has been above advanced in reference to the essentials of inflammation, it would seem, moreover, to follow, that the dispute is somewhat idle and unmeaning, whether inflammation be weakness or strength, action or torpor, obstruction or other impediment; it is all and every thing as the general frame and local incidents shall vary; and both as to pathological essence and practical indications abstract views ought to be kept as much as possible from influencing judgment.

273. In reference to the modes in which inflammation terminates, it may be said, that the term resolution is generally meant to express that recovery from the morbid state which is effected without the intervention of any disorganising process. But this event, strictly speaking, is not perhaps possible, since the existence of the derangement supposes, as above intimated, some degree of disorganisation. Even the most simple case then of resolution seems to imply some degree of absorption, and it is probable that the remedial agents that are had recourse to, under the notion of subduing vascular action, effect their purpose in part by giving an impulse to the absorbing faculty. The readiness with which adhesion takes places under inflammation, between membranes that are in apposition, is a proof of the rapidity with which inflamed vessels pour out lymph; and this lymph, if not again taken up into the circulating mass, often becomes organised in a very few hours; a process this which is one of the most remarkable in the whole circle of animal movements, and which, on account of its important bearing upon pathology generally, we shall illustrate by the recital of a case in proof. A man was operated on for strangulated hernia at seven o'clock in the morning. The hernial sac was laid open, and the gut, which proved to be a portion of the ileum about six inches in length, was attentively examined previously to its being returned into the cavity of the belly. It had the natural polished surface peculiar to intestine, and although its vessels were tinged with blood it did not appear that they were uncommonly numerous. After the operation the symptoms did not abate so much as might have been expected, and during the afternoon a pain was complained of in the lower part of the belly. There was no passage by stool, and next morning, about seven o'clock, the pulse was scarcely perceptible; the skin was cold and clammy, and at about twelve o'clock at noon the patient died; having lived twenty-nine hours after the operation.

274. The body was opened, and the portion of gut which had been strangulated was found considerably inflamed, the external surface having lost its natural polish, and having several small portions of exudated coagulable lymph adhering to it. The vessels of the gut were minutely injected; the arteries with a red colored injection, the veins with a yellow one. Upon examination afterwards all these adhering portions of coagulating lymph were found to be injected, having a considerable artery going to each of them, and a returning vein which was larger than the artery. It is evident, therefore, that the coagulating lymph was laid upon the surface of the gut after the operation; and we cannot suppose, says the narrator, that any such process as forming new vessels could have been going on during the last five hours of life, when the pulse at the wrist was scarcely to be felt, and the powers of life were so much weakened in every respect. We must therefore conclude that the whole operation of throwing out coagulable lymph, and supplying it with blood vessels after it had become solid, was effected in less than twenty-four hours!

275. If inflammation be not resolved, or it may not have terminated by effusion, or this new and adhesive action, suppuration, or the formation of pus, is the next step in the process. On the manner in which pus is formed, opinion was exceedingly vague to the time of Dr. Morgan and the justly celebrated Mr. John Hunter. Even Pott, in his estimable works, alludes to the formation of pus as if it were some how or other the consequence of the solid parts being melted down; and in the first lines of Dr. Cullen this same theory is broached. The general sentiment among pathologists of the present day is, that pus is a peculiar secretion from vessels in a certain condition, but what the precise state is which originates pus seems still an unsettled matter. Pus, indeed, is evidently engendered under different circumstances of the vessels, and, although it is usually the result of inflammation, it sometimes seems to be the consequence of an irritative action which is under the grade of positive inflammation; as when it is secreted from mucous surfaces after a long continuance of chronic, but not perhaps truly of inflammatory ailment.

276. Gangrene is in fact the death of the part which the disorder implicates; the rush of the disease has proved too violent for the organs to bear; the living reaction has failed of accomplishing its purpose 'and the laws of animal chemistry, thus far held in subjection by the superior sway of the living power, acquire an ascendancy; a play of chemical affinities takes place, and putrefaction or a decomposition of the organised

substance, and a restoration of its constituent parts to their elementary forms, necessarily ensues.

277. We shall not proceed further in the consideration of the inflammatory state, as the subject, in a more enlarged and detailed manner, will fall more properly to be noticed under the head of SURGERY; and it is now in order that we pass on to the topic of fever generally. This word fever, in its extended application, constitutes, says Dr. Uwins, a curious example of the principles upon which nomenclature is founded in medical science. Observers of morbid phenomena could not have been long in ascertaining that in some deviations from health the heat of the body is preternaturally increased; and, connecting this leading and characteristic effect with a vague idea of causation, they thus made a single symptom in a manner expressive of a whole cause. But as animal heat, or the temperature of the body, is equally augmented under very different circumstances of the frame, it became necessary to seek for epithets further expressive of these varieties; and hence the adjectives nervous, bilious, inflammatory, putrid, were attached to the generic term fever.

278. Now that local condition of vessels to which we have above adverted, under the term inflammation, never takes place to any great extent, or lasts for any length of time, without giving rise to those irritative actions throughout the whole frame, by which, or in conjunction with which (to avoid language expressive of cause), the heat of the whole body is increased. In this case a sympathetic or symptomatic fever is said to have taken place. But it is not always that fever, or an increase of heat, is traceable to these local circumstances; and, when it is not so traceable, the disease has been named in the schools idiopathic, as contradistinguished from sequential or symptomatic fever.

279. We know not the reason, even when there is local inflammation, why such topical disturbance should produce systematic derangement; but when the general derangement occurs without such commencing point, or starting post, we seem to be placed in still more difficulty on the score of pathological explication. This last difficulty, indeed, some pathologists have endeavoured to prove dispensable; they maintain that fever is in reality *always* a symptomatic expression of partial disturbance, although the local derangement shall not in all cases be the actual subject of perception. But there is a difference of opinion among these theorists, as to the first link in the chain of morbid process. Some maintaining that it is the brain, others that it is in the membrane which lines the alimentary and intestinal canal, and some considering that the chylopoietic or assisting chylopoietic viscera are the parts upon which that morbid irritation first falls, which comes thus to extend itself through the frame generally, and each appeals to post mortem appearances in support of his particular theory; that is, the speculatist who asserts that fever is inflammation of the brain, virtually from first to last, calls your attention in the first place to the derangement of the animal functions by which fever is constituted, and which, as he asserts, implies brain affection; and in the next place he tells you, that you will generally find, upon inspecting the head of an individual that has died of fever, the presence of marks which indicate that an inflammatory process of disorganisation has been proceeding in this part during the existence of the malady; that this disorder of the animal and intellectual functions is very characteristic of fever, and in a degree almost essential to its existence; and that vestiges of inflamed brain are frequently seen; while others, admitting these facts, refuse their assent to the position that fever is inflammation of the brain, and inflammation of the brain fever, alleging, that a great degree of disturbance in cerebral functions may exist without the necessity of inflammatory action, and that the post mortem showings are rather consequential and incidental than primary and of necessity. It is well known, they further say, that inflammatory and other disorganising processes occasionally take place in the bowels and viscera under the presence of fever, and that the disorder in question has therefore as much title to be considered inflammation of these parts, as of the brain itself. Some, indeed, do consider that the essence of febrile action consists in an inflamed or irritated state of mucous surfaces, while others argue, that the malady consists mainly in general perturbation, and that inflammation, although of common occurrence, during its progress, is not essential to its existence.

280. A febrile paroxysm consists, more or less distinctly marked, of rigor, then of heat, and, lastly, of perspiration; but, in tracing the rationale of these several steps, we find ourselves involved in much that is obscure and perplexing; and that partly in consequence of the ignorance to which we have before adverted, in regard to the laws by which both actual heat and the sensation of heat are instituted and exercised in animal existence. The disturbance, however, of the corporeal movements by which the first link of fever is constituted, whatever be its actual and precise nature, seems a something, which in one moment, in uno ictu, as Fordyce expresses it, runs through the whole fibres, and texture, and functions of the sentient organisation; it is a shock to which succeeds the rigor, which rigor, though expressed in English shivering, is not exactly the same sensation as cold, although it is more like it than any other sensation; and to account for the sudden generation of cold would be, in some measure, to account for the feeling in question. There is in the shock and rigor of fever, a sudden induction as it were of quiescence, a temporary suspension of the ordinary movements; and hence, in part at least, seems to arise the perception. It is a curious particular, as remarked by Dr. Fordyce, that the power of diminishing heat, without such heat being given out to surrounding media, is common to the first stage, or preliminary quiescence, of fever. The body seems in a manner to lock up its own heat; or, perhaps more properly speaking, by ceasing for a time its action, ceases in the same ratio to engender or manufacture heat. We probably then are permitted to go thus far in the explanation, viz. that an abrupt suspension of vital forces occasions the generation of cold, and

causes a shrinking and contraction of the extreme vessels, and that, after this suspension and contraction existing for some time, excitability is as it were accumulated; so that, when the system recovers from it, the ordinary reacting movements or external impulses cause undue impetus, and hence the commotion constituting the irritative portion of the series of actions by which consecutively fever is made up. This is, in fact, the mode in which the disciples of Stahl and of Cullen would explain the phenomena of fever; only that in the schools of these celebrated teachers, especially in that of the former, a sort of intelligence was supposed to be connected with these reacting impulses, to the directions of which it behoved the pathologist and practitioner to listen. Thus, to that primary shrinking the term spasm was applied by Cullen, with some looseness perhaps of phraseology, and a phraseology to which many objections have been advanced; but it does not appear that the successors of Cullen, who have loudly called out on the absurdity of his terminology and doctrines, have substituted others much more precise or satisfactory; and from the whole it would appear that the perturbation of fever may be present without the actual presence of inflammation, but that it seldom lasts long without being productive of the inflamed state, as it is natural to expect would be the case when circulating impulse is exercised with such irregularity; the nervous power directing the arterial action in such sort as to cause the facile production of topical inflammation and all its consequences.

281. When fever, instead of suddenly rushing as it were upon the subject it attacks, occurs more slowly and insidiously, as in the instance of its proving consequent upon mental uneasiness, then, we believe that the brain for the most part partakes essentially, if it may be so said, of the disorder's essence, and that the disorder of the whole system is the result of an inflamed state of brain.

282. But how, it may be asked, is the increased heat under fever explained? and what is the pathology of the perspiration which succeeds?

In the hot stage of fever, says the author whom we are now following, it has always appeared to me that phenomena present themselves inconsistent with the chemical theory of animal temperature, even had we not been furnished with the refuting experiments of Mr. Brodie, before alluded to. During the heat of fever there is often much less change effected in the pulmonary organs, than while the body is free from disorder. Nay, the breathing an oxygenous and vivifying atmosphere will often serve to cool, while azotic or carbonaceous air will heat the body; this is so conspicuously the case, that some have proposed, as, in part at least, an explanation of fever's essence, the circumstance of carbonaceous rather than vivifying blood circulating through the brain, and producing the sensorial and other disturbance. Be this as it may, we certainly are compelled to ascribe the morbid heat, under the affections supposed, to a derangement in the sentient faculty, and to the commotion which the disorder induces, rather than to any decomposition of the air which the individual respires. In this announcement, however, we rather cut through than untie the knot, and both the primary cold and subsequent heat of a febrile paroxysm are in respect to their rationale still involved in some obscurity, and connected in some hitherto unexplained way with vital peculiarities.

283. Perspiration is the final stage of a fever fit; and it becomes a question how this is brought about? and upon what principle it is that synchronously with the production of sweat, the body's temperature is reduced. At the time when the pulmonary theory of animal heat was generally admitted, it was ingeniously conjectured whether perspiration is not in all instances the converse of respiration in regard to its agency in the system; or that, as the lungs are the inlets of the calorific principle, so is the surface of the medium through which the heat is prevented from rising too high. 'That an animal,' says Dr. Currie, 'possesses to a certain extent the faculty of rendering sensible heat latent, or to speak more philosophically of reducing caloric from a free to a combined state, in cases in which the stimulus of heat might otherwise overpower the living energy, there is reason to believe from a variety of experiments and observations; and that this in part is performed by perspiration from the surface, can scarcely admit of a doubt. The process of perspiration, which is continually going on from the surface of the body, is in this point of view the converse of respiration. As in respiration a gas is constantly converted into a solid or fluid, and thus heat is evolved, so in perspiration a fluid is constantly converted into a vapor, and thus heat is absorbed. A vessel filled with water, and exposed to the atmosphere, cannot be raised above 212° of Fahrenheit by any quantity of fuel, because, as heat is supplied from below, evaporation carries it off from the surface; in like manner we may suppose the heat of the human body to be kept uniform by the evaporation from the surface increasing or diminishing, according to the quantity of heat extricated from the system, or received from the surrounding media.'

284. To a certain extent this doctrine, of perspiration being a regulator of heat, may be admitted. But it ought to be recollected that we have agents that are capable of reducing the heat of the body, without producing sweat; and Dr. Currie himself admits that, from some experiments in the hot bath, it appears that the temperature of the body is with difficulty increased after the sweat begins to flow, although there is, of course, no evaporation from the surface while the body is immersed in hot water. Our theorist meets the objection, which starts up from this source, by supposing that perspiration is a cooling process even in its being engendered internally, and before it breaks out upon the surface, from the fact of this fluid having a greater capacity for heat than the blood, and thus absorbing or reducing temperature in the moment of its formation.

285. But it has been said that the matter of sweat is actually secreted in as great abundance during the heat of fever as after the paroxysm

has declined; and we know also that many agents prove cooling without proving sudorific; and, upon the whole, we must conclude that, as in the instance of natural and morbid heat, so in the case of its modification and reduction, there is still much that does not admit of explanation by the assumptions and inferences of chemistry; and that vital actions and sentient impulses must be taken into account before we can take one secure step in the way of tracing the rationale of function.

286. Why, it is natural to enquire, does not sweat immediately result upon the reaction and heat of fever? Why does the surface for a time pertinaciously retain its dryness and heat, and then all at once give way and become bathed in perspiration? For suppose we allow the correctness of the statement made above, that sweat is produced as freely during heat as after the declension of heat, even then we must admit that the vessels on the surface are in a different condition, under the actual appearance of sweat, from that of dry heat. Dr. Cullen and his disciples would reply to this query, that the rush of blood and newly excited action eventually succeed in dissolving the spasm of the small vessels, and thence the resulting phenomena; but, besides that this is saying it takes place because it does take place, we must suppose the subsidence of the spasm, or the giving way of contraction in the extreme vessels, prior to the full establishment of reaction. Dr. Park has endeavoured to refer these circumstances to a similar law with that which takes place in some of the hollow muscles, as of the bladder and rectum, in which the sphincters or outlets always act in opposition as it were to the organ itself; when one is in a state of contraction, the other is in that of relaxation, and vice versâ. In consistency with this principle, he says, that the exhalants may be received or furnished at their extreme points with a species of sphincter agency; and that, when the vessels on the surface give way before an inordinate rush of blood, the extremities contract to retain it, and that this contraction only ceases when the retaining power of the vessel is stretched to a certain pitch; as we micturate of necessity when the urinary bladder is full. Is not this hypothesis open to the following objection, even if otherwise tenable? that it supposes the capillaries to be organs of mere retention and transmission, not, as they in reality are, actual secretory vessels. Were it the mere rush of blood that the shut mouths of the extreme vessels retain, the discharge when constriction is overcome ought to be blood, or at least the thinner part of that fluid, and not, as it proves, a new secretion.

287. With respect to the exciting causes of fever, opinion is still as various as in reference to the rationale, or proximate cause, as some express it, of the febrile state. This question of the excitants of fever in part involves another, viz. what are the kinds and species of fever? Some assert that fever, whatever type or external character it may display, is always one and the same thing, and that there is no difference except in the imagination of the nosologist, between the malignant plague of the Levant, and the low, or as some call it the typhoid, fever of a London alley. Others again divide and subdivide to an enormous amount, under the feeling that every new modification of the ailment, in acknowledging a distinct source, demands a distinct appellation. While some steer a middle course, and imagine that fevers, though in one sense they are identical, are susceptible, in point of fact, of greater divisions than the identifiers of disease acknowledge. Genuine fever, say one class of pathologists, never can originate without the agency of contagion; others, on the contrary, go so far as to deny the contagious quality of any fever except in the instance of certain specific disorders as the small pox; while a third party are ready to admit that contagion is an agent in the production of fevers, but at the same time contend that the disorder may be elicited from other powers, such as the undue influence of temperature, famine, repletion, filth, confined air, and even mental agitation.

288. The words contagion and infection have sometimes been used synonimously, and this has occasioned some want of precision in the reasoning, and uncertainty in the inferences, of speculatists. Contagion, says the writer whom we are now principally following, is, by the general acceptation of the term, a something which, coming in contact either immediately or intermediately with the body of an individual previously in health, engenders a disease in that individual of a nature precisely similar to its own; it implies, in a word, specific poison. What is infection, as opposed to contagion?—If we take a journey to Constantinople while the plague is raging in that city, and if by consequence of our residence there we fall sick of the plague without having come into contact with the matter that shall have emanated from the body of another person who is the subject of plague, we receive an infectious malady. Here then is stated to be the difference between an infection and a contagion; that the one is atmospherical, or only through the medium of the unhealthy air communicated, while the other implies communication, either direct or indirect, with a something issuing from the body of the sick. In either case, indeed, the contact with a poison is, strictly speaking, supposed; and hence there is some impropriety in basing the notion of difference upon the assumption of different operation. 'I am disposed to think,' says our author, 'that much of the intricacy that attaches itself to the question of contagion and infection originates in this very source; that is, a variety in modus operandi is presumed which is really non-existent. Let us imagine that a patient dies in the Levant of the disease called plague, and that the clothes in which he died are conveyed to this country imbued with the poison of plague. An inhabitant of our metropolis procuring and putting on these clothes might be affected with a certain dose, so to say, of disease; but still, though the virus may be as active in se as had the same appropriation of the habiliments been made at another quarter of the globe, yet the resulting distemper might nevertheless be various; and in that case you would say of the individual that he had taken an infectious as well

as contagious distemper. In this way then the question may be viewed as standing out in a tangible form. Is there any reason to believe that some disorders are entirely of an abstract nature, dependent solely upon their several exciting sources, without reference to time, place, or circumstance? Or does the modifying power of place always, to some extent, operate upon the nature and aspect of a distemper?' 'For my own part,' continues the writer we are quoting, 'I am disposed to think it does, so that though in some cases I incline towards the sentiments of the anti-contagionist, I in another recede from his inferences, even much further than does the contagionist himself; for I believe that, from the most decided case of small pox, down to a nursery cold, there is something communicable in the maladies, and something operative in the atmosphere.'

289. The author goes on to other illustrations, which we have not space to quote, of the same principle—that is, he endeavours further to demonstrate, that even those distempers which seem, so to say, the most abstractedly dependent upon their own peculiar sources, are in some measure modified by atmospheric influences, and that thus specific contagion falls by insensible degrees into malignant, and that again into mild or general disorder, as the succession of time or the variation of circumstance directs. Having, however, admitted that on these points there is much to learn, much to unlearn, and much probably that will be for ever hidden, he concludes the section of his book which refers to the excitants of fever, by the following announcement of facts and opinions:—

290. There is in all fevers a tendency to periodical accession and decline, but in some cases this is so complete and so marked that the patient is left during the intervals in total exemption from the disorder; hence the term intermittent. In other instances, though the malady gives way in part, it does not wholly. Now, the intermittent shapes of fever have been observed much more frequently in marshy situations, or where shallow stagnant waters abound; and they have on this account been usually attributed to a poisonous exhalation of miasm arising from the decomposed materials of a soil thus circumstanced. Others have argued that there is no necessity of interposing the notion even here of a specific poison, since the coldness and dampness of the country are quite sufficient to account for the effect. When, however, we find that in some situations not marshy, but otherwise unhealthy, intermittents do not, or but seldom appear; when we see that the draining of lands from shallow stagnant waters has considerably lessened the frequency of these fevers; and when we recollect that the neighbourhood of deep waters, though equally cold, is not so insalubrious as that of a marshy vicinity, it appears to be carrying a disposition to generalise too far to question the specific agency of marsh miasmata. But the influence of this may be much modified by other agents; and, in cases where we have very high variations and sudden vicissitudes of temperature from the sultry day to the damp foggy night, and where at the same time the land is low and marshy, there we meet with modifications of yellow and intermittent fever under the shapes and denominations of bilious remittent. Again, let these circumstances of soil and temperature operate in conjunction with animal decomposition, and the resulting disorder assumes more of what has been called a putrid type, still retaining some of the features either of remission, intermission, or yellow hue, that have been imparted to it by its other excitants besides that of the main and master one. Whether, then, we shall name all these fevers differently as they thus assume various shades and modifications, becomes in some measure a dispute about words, only that it is important to recollect that these varieties are rather local, endemic, and incidental, than inherent, abstract, and essential.

291. The remaining orders in Cullen's first class or pyrexia are exanthemata, hœmorrhagia, and profluvia. Exanthamata is a term applied to diseases which break out on the surface of the body in the form of rashes or otherwise. The theory of these diseases is often very difficult and intricate. The ancients, who were for the most part contented with generalising inferences of not a very precise nature, supposed a sort of internal commotion of humors, which, after battling about for some time, settled on the surface, something after the manner of fermenting materials, which eventually come to subside into their respective localities; indeed the humoral pathology, as it has been termed, of more modern times, reasoned in some measure after this sort; and averse as we may be from falling into these notions, now that the laws of secretion and excretion are more scientifically traced, we must still, nevertheless, admit that there is in the phenomenon which some of the rashes exhibit not a little that justifies the crude analogies alluded to.

292. It is right to remark here that Dr. Cullen confines his views of the exanthemata to those affections of the skin which are not only attended with, but which are actually ushered in by, fever; and it is through the means of this fever that the disorder is thought to work its own cure; for it is hereby that a general determination is made to the surface, and the morbid poison is thrown off from the system.

293. 'When a febrile poison producing a cutaneous eruption is generated, or has been conveyed into the blood, a small degree of fever is sufficient to throw it upon the skin; and, if it exceed the proper extent, the specific virus will be multiplied, and the fever itself may become a source of real danger. It was formerly the practice to encourage the fever by cardiacs, a heated atmosphere, and a load of bed clothes, from an idea that we hereby solicit a larger flow of morbific matter from the interior to the surface. The fact is unquestionable; for, be the exanthema what it may, the skin will hence in almost every instance be covered with eruption. But it did not occur to the pathologists of those times that the morbid virus was an animal ferment, capable of multiplying itself by accessories; and that heat and febrile action, beyond a very low medium, are among the most powerful accessories we can communicate. And hence

the advantage of applying cold water in scarlet fevers, and cold air in small pox, with a view of mitigating the fever that often accompanies these diseases; for, by diminishing the febrile violence, we do not as was formerly imagined lock up the contagion in the interior of the system, but prevent it from forming afresh and augmenting there.'

294. To this law, however, of moderating rather than abetting excitement, some limits must be made in theory and practice; and here it is of importance to remark, that of late years a connexion has been traced between the action of the outer skin, and internal membraneous surfaces, and that in especial reference to febrile disorders that are expressed by rashes. The connexion seems to be of that nature which is denominated by Darwin reverse sympathy, which had long ago been recognised in the case of catarrhal irritation, but which has recently been more particularly traced and applied to the affection now under notice. Suppose the whole surface of the body to be covered with a thick crop of eruptions, if you too precipitately arrest the morbid processes which these eruptions imply, you thereby cause the surfaces which line the interior, both of the alimentary and aërial passages, to take on an action, at least somewhat similar if not precisely the same, as that which you have interfered with on the exterior. In some instances this vicarious sort of connexion is more marked than in others; but in all cases of skin activity it is in a greater or less measure conspicuous. In all it requires to be attended to in practice, and, indeed, in modern medicine is attended to, much to the credit of the science, and to the benefit of the patient. It may be right just to remark here that the connexion appears to have some relation, at least, to kind as well as degree; for in the eruption of scarlet fever, and especially measles, though the cutaneous disturbance may not be nearly so great as in the instance of small pox, the internal tendency, upon either natural or artificial repression, appears greater. It will be found necessary in practice to proceed under a recollection of this fact, and to be wary of bringing down the irritation on the surface with too much freedom, where the internal tendency to the vicarious irritation now referred to is thus conspicuous.

295. The next order is hæmorrhages, in which there is some degree of analogy with inflammations; that is an inordinate impulse given to the blood may produce the discharge in a direct way, as in the case of active inflammation; or the discharge may be brought about by want of resisting or retaining power in the vessels themselves, the impulse not being much more than ordinary. It is proper, however, to take into account, when we are considering the pathology of hæmorrhages, that a discharge of blood does not necessarily imply an actual rupture of vessels, since the impetus may be so great as to force blood through the terminal capillaries, or those small vessels which terminate by open mouths upon surfaces, and thus may a very considerable profusion be produced, while the coats of the vessels remain unbroken. In this case inflammation and hæmorrhages are exceedingly analogous: but, in the case of discharge of blood, the discharge in some degree operates its own remedy, that is, as far as the inflammatory process is concerned, although a new disorder is sometimes engendered by extravasation into parts which, having no outlet, are incapable of immediately ejecting this foreign matter.

296. Hæmorrhages were formerly conceived to have great dependence upon external circumstance, that is, to be influenced by variations in temperature and aërial density; heat expanding the circulating blood beyond its ordinary tenacity, and the varied states of rarefaction in the air causing a varied condition in the rarefaction or condensation of the fluid while flowing in its vessels; and, although the laws of physics and chemistry are ever held in subordination and check by the commanding energies of vital forces, it is perhaps questionable whether the pathology of the present day is not too regardless of external agents in the rationale of internal processes. Hæmorrhage from the nose and from the lungs is not seldom induced by breathing an air more than commonly rarefied; and without going to the full length of Hoffman, when he talks of orgasm, ebullition, and turgescence of blood destroying the systaltic and elastic power of the vessel, and thereby inducing congestion, distension, and rupture, we may at least subscribe to the doctrine of some immediate change in the blood's condition, as caused by external agents, beyond the influence of these agents as mere vital excitants.

297. Persons ascending elevated regions, when the atmosphere is less dense or more rarefied than that immediately surrounding us, have been seized with hæmorrhagic attacks, which could not be ascribed solely to exertion, but must be in part referred to atmospheric change: a proof this that even in circulating blood some direct alteration may be effected on its volume by the varied circumstances of external exposure; even here, however, we are to take into account the probable influence of the supposed change upon the living fibre as well as upon the circulating fluids; and upon the whole it seems right to recognise, as above intimated, the superior power of vital causation, while we admit, in a qualified and subordinate way, physical and chemical agency.

298. When hæmorrhage takes place from obviously exciting causes, such as a flow of blood from the nose in consequence of a blow, or when spitting of blood is induced by violent exercise of the lungs, it does not seem very difficult to follow the steps of the morbid process; but the occurrence of spontaneous hæmorrhage, as of spontaneous inflammation, brings with it a little more of difficulty in respect of explanation; and here we must have recourse to the idea of plethora, and to an irregularity in the blood's distribution arising out of that state of the system to which the predicate of plethora is applied. On the nature and essence of plethora much controversy has arisen; and, indeed, by some the possibility is denied of more blood being at any given time in the body than the vessels can conveniently contain and carry. It

is averred that the secretory and excretory organs would take care that this should not be the case, and that the demand upon them is ever in proportion to the ingesta or matter received from without. But, were these functions always thus true to their charge, very little of disordered action would ever be manifested; and the fact is, that the very tone of the system which produces appetite, free digestion, and, in consequence, occasions more blood and chyle to be formed, is that condition which contracts the blood-vessels and the secernents at the same moment, and thus occasions a more than due quantity of blood to be contained through the whole of the circulatory organisation. We know also that, for the secernents and excretories to be kept in a due condition of activity, a certain quantity of exercise is required on the part of the individual. In default therefore of the exercise a plethoric state may be induced, since rest in some conditions of vigorous stamina may not be equal to causing a failure of appetite and ingesta. This species of plethora, if it be admitted, implies a stenich diathesis, to use the phraseology of some pathologists; and, although in itself not disease, certainly predisposes to it, by rendering the system more obnoxious to the effect of the slightest and otherwise scarcely operative irregularities.

299. But it is further conceivable that the vessels may be overladen and over distended while the actions of the system are in respect of tonicity or sthenic condition rather below than above the ordinary standard. In this case, however, the blood would be more tenuous as well as in larger quantity, and the morbid inclination would be more towards the next order of disease, the profluvia; or rather it would be towards serous effusion and dropsical accumulation, on the rationale of which a few words will be said under cachexia.

300. The schools have admitted a plethora ad molem, which implies an actual expansion of blood in the vessels; and this in some degree may have place if what has been advanced on the subject of aerial density or tenuity and their effects has any foundation in fact.

301. *Profluvia.* A certain kind and quantum of excitation in the excretory organs increases their natural discharge; but a diminution as well as increase in this excitation may also be productive of inordinate discharge. Thus coryza from the nose, and tears from the lachrymal glands, may appear in superabundance from mere exposure to cold, which being a deprivation of heat is in fact a deprivation of stimulus. There would seem at first some difficulty in reconciling these 'hot and cold blowing' phenomena, but the following explanation may be deemed sufficiently satisfactory. 'The absorbent vessels become torpid by the diminution of the external heat sooner than the secerning ones, which are longer kept warm by the circulating blood, from which they select the fluid they secrete; whereas the absorbent vessels of the nostrils drink up their fluids, viz. the thin and saline part of the mucus, after it has been cooled by the atmosphere. Hence the absorbents ceasing to act, and the secerning vessels continuing some time longer to pour out the mucus, a copious thin discharge is produced, which trickles down the nostrils in cold weather. This discharge is so acrid as to inflame the upper lip, which is owing to the neutral salts with which it abounds not being re-absorbed; so the tears in fistula lachrymalis inflame the cheek.

302. But there are circumstances connected with morbid activity in the secernent vessels which are exceptions in appearance to the more general one of increased secretion being equivalent to increased excitation. In the first case a given quantity of excitement, or that quantity applied under a given state of the secerning organisation, shall arrest secretion or flow altogether. Shall we say here that both the exhalants and absorbents are in a state of increased action, but the absorbents have obtained the mastery in the contest; or shall we suppose, with Dr. Parr, a sort of opposition between the small vessels and their sphincter extremities; or shall we confess at once that we have much of difficulty to grapple with when we trace functional relation to exterior agents? Again the flux shall be continued by habit after all extraordinary excitation is gone by. By habit! What do we mean by this term? Merely a statement of fact; and it is really not easy to say why a thick ropy secretion should be continued to be poured out from the mucous surfaces, after the cessation of that cause from which the flux had primarily proceeded. The absorbents here would seem to do something more for the poured out matter than merely drink up its watery and saline parts; for the secretion often gradually changes in kind as well as consistence; and at length, under particular conditions of the part and of the frame, slides, as we have before intimated, into purulent condition.

303. With these remarks we conclude our preliminary comment on the first class of Cullen's system, and we now proceed to observe in the same cursory and prefatory manner on the second division of the system, viz. neuroses, which comprises the four orders comata, adynamiæ, spasmi, and vesaniæ.

304. Comata. 'Diminished voluntary motion with torpor or a suspension of sense. Here, we are told, an obvious and large objection immediately rises up against classifying attempts. Let a few branches of blood be ruptured and a little blood be poured out upon the brain, by which primarily and properly a mere hæmorrhagic disorder is constituted, and you have instantaneously all the symptoms presented to you of Dr. Cullen's first and most important order of nervous ailment. Again, the two genera of this order are apoplexy and palsy; the latter of which often occurs without coma, and is, in truth, a mere adynamic affection; so that the class neuroses in its leading definition, and in both the genera of the very first order, is far from correctness either in admission or omission.

305. Coma is usually produced by pressure upon some part of the encephalic mass, and this pressure for the most part occurs from fulness of vessel, or from extravasation; but that this is not always the case may be analogically inferred from the phenomena of a drowsiness that is below the

grade of actual disease. Let an individual, for instance, feel himself almost irresistibly impelled to sleep, under the ordinary excitants by which he is surrounded; but add a larger quantity, or subject him to a different kind of excitement, and his soporose tendency immediately changes into wakefulness and vigor. Now in this case we cannot suppose that pressure on the brain was the cause of the drowsiness, or the removal of that pressure the occasion of the wakefulness; the altered circumstances and feelings must surely have reference rather to some unknown change in the sentient energy than to the mechanical condition, if we may so express it, of brain and nerve; and an inference has been adduced from these occurrences against the theory altogether, which ascribes the sopor of apoplexy to either fulness or pressure. Even in those instances of sentient abolition that are unquestionably connected with hæmorrhage upon the brain, some theorists will pertinaciously contend that the hæmorrhage is rather a consequence than a cause of the suspended functions, and that it is in the derangement of nervous energy that you are to look for a satisfactory exposition of comatose circumstance.

306. But we believe the moderate and unsystematic or independent observer will only permit the fact referred to, of volition and sense being interfered with, where no pressure can be supposed to influence his mind against the common theory of apoplexy to a certain extent. He will be led by reflection on it to qualify, not to reject, the principle. He will in some sort accord with this theorist who talks of broken down nervous power, and with that who refers the whole business rather to altered circulation than to actual pressure; but he will also recollect that the Parisian beggar could at any time bring an apoplexy upon himself, by merely pressing upon a denuded portion of the brain; and he will duly recognise the fact, that a man who was but a few short moments since in health and spirits may be now lying before him snorting under the succumbence of hæmorrahagia cerebri.

307. The fault in this, as in other parts of pathology, consists in assuming that there must be one spring and source of ailment to the exclusion of all others; and the error here has not been limited merely to theoretical speculation. It is to be feared, on the one hand, that the lancet has been systematically withheld at the expense of life; and that, on the other, large depletions have acted in aid of disordered forces to determine the patients' untimely fate. An intermediate but not a neutral course seems to be the safest plan of procedure, and a great deal must be left to the practitioner's judgment and to the particular circumstances of the individual case. But it is theory rather than practice to which we are now attending.

308. Of the adynamiæ, the second order in this second class, we may observe, the existence seems sufficiently well established. It is easy to conceive of defective power in the involuntary functions from defective nervous supply, without resorting to the condition of blood-vessels for an explanation of the circumstance. That these functions may thus be interfered with, by some unknown condition of that part of the nervous organisation under the influence of which they are exercised, all experiments and observations bearing upon the point tend to prove, and none more so than the recent ones of Dr. Wilson Philip; who not only, by dividing the nerve which supplies the digestive organs, puts a stop to the process of digestion, but who also causes digestion to be continued or resumed, by so placing the animal experimented on under the influence of voltaic electricity that this latter is made a substitute for the nervous energy.

309. Adynamic disorders, or, in other words, disorders of defective power, have often been supposed when inflammatory conditions had been really present; and to say of disease it is a defective power, without minutely investigating all its phenomena, is to let loose upon our minds a speculative principle which may be highly injurious to our patients when carried into practical application. But at the present day the tendency of theory and practice may be rather to the opposite extreme; and, in our endeavours to trace every thing up to tangible sources, it may be questioned whether the ideas of congestion and inflammation have not too much superseded the recognition of nervous agency.

310. Spasmodic affections, which are made to constitute the third order in the present class, are quite as difficult of explication as arè the adynamic ailments. We have assumed the deprivation of power, causing the latter to be an unknown condition of nerve, and of the spasm we may predicate the same thing; for if we admit of irregular flows of nervous fluid, as the source of those irregular actions in the fibrous part of the frame to which the term spasm is applied, we set out without any other guide than that of a petitio principii, and wander we know not whither.

311. Even the axiom that has been admitted by some to an unlimited extent 'debilitas gignit spasmum,' spasm originates in debility, cannot be received into pathology without much qualification; for when an individual is thrown down in violent convulsions from merely a few thread worms being lodged in the rectum, and becomes immediately himself again upon the expulsion of these 'minute instruments of mighty mischief,' you can scarcely say that it was weakness which caused, and it is returning strength which has subdued the disorder; though, as far as the convulsion itself is concerned, there may be some propriety in placing it to the account of debility, since convulsion consists in fibrous contraction not being brought up to the due pitch which is demanded for orderly display.

312. Among the spasmi Dr. Cullen has introduced some of his genera, in violation of his own principles. Asthma, dyspnœa, and hooping-cough, might still perhaps retain their situation without very strict investigation of right or claim; but who can see pyrosis and diabetes introduced as spasmodic disorders, without thinking that either the scheme which admits them into the class is defective, or that insuperable difficulties connect themselves with all schemes.

313. The vesaniæ are those derangements

which are commonly considered as distinctly mental. It has, however, been asserted that 'every nervous disorder is a degree of insanity;' and there is some rectitude in the notion which this sweeping assertion is meant to convey. When feeling is no more than commensurate to obvious circumstance, the individual thus feeling, or thus perceiving, is considered to be under a degree of delusion corresponding with the intensity of the affection; and in delusion consists insanity. But here lies the difficulty in determining upon the existence of insanity, that a standard of sanity is assumed which it is difficult to substantiate. What, says the author now under contribution, is motive to me is not to another; and, while I call the miser mad for loving money merely for money's sake, I in a measure forget that his feelings with regard to the value of money are absolutely different from mine; and so in respect of what are called and considered imaginary ailments. Who shall say that the despairing hypochondriac, contemplating and effecting the horrid purpose of suicide, feels or acts in less consistency with his state of sentient being than does the happy individual who gratefully participates in the blessings of providence, and does all in his power to preserve his life both from a sense of duty and a feeling of delight?

314. With respect to the altered condition of brain and nerve, upon which insanity depends, we know nothing more than we do respecting the cause of convulsive agitation, or adynamic torpor. We are fully conscious that there must be some bodily change, and that of a serious nature; for the idea of merely mental disorder, abstracted from corporeal engagement, cannot be admitted into pathology; but, of the essence of the change produced, we are often from first to last profoundly ignorant, and the suddenness with which both its visits and departures are sometimes made is inconsistent with our notions and knowledge of organic disorder. When, indeed, we meet with opportunities of examination after death, there is scarcely any condition of brain not found at one time or other; but there is a great want of uniformity in these appearances. They are most of them occasionally found when the disorder had not been insanity; and it is further impossible to say how much of the change has been cause and how much consequence. When, says our author, the vascular theorists refer all the aberrations of nerve and mind to congestive and inflammatory states, they make the same mistake here as they do in reference to pyrexial pathology, by putting the acted upon in place of the agent, and by assuming the existence of states that are incidental as if they were necessary and invariable; so again do your chylopoietic speculatists, who will have it that the stomach must be mad before the man, in the same sweeping way that they will not admit of an accidental blotch on the body's surface, without considering it an index of digestive derangement.

315. The distinction between hypochondriasis and melancholia, it must be conceded, has been too nicely drawn out upon the ground that the one is an adynamic, and the other a vesanic ailment; but that absolute madness of the melancholic cast often takes firm hold of an individual, without at all interfering with digestive integrity, must be allowed by every one who may not have committed himself beyond recall to the catholicism of the chylopoietic creed. Cullen on the other hand seems to be in an error, when he states melancholia to be partial insanity without dyspepsia, and mania to be universal madness; for the one is often as complete and universal as the other, and the difference, like that in febrile manifestation, is rather to be taken from the person affected than from the thing affecting: 'such a system of division is contrary to what manifest propriety suggests. It is making the plant, from an acorn dropped upon a rocky soil, not an oak because it does not rise to the height or spread to the extent usual to the king of the forest.'

316. The remarks of Dr. Haslam on this head are well worth the attention of the nosological subdivider. As the terms mania and melancholia are in general use, says this writer, and serve to distinguish the forms under which insanity is exhibited, there can be no objection to retain them; but I would strongly oppose their being considered as opposite diseases. In both the association of ideas is equally incorrect, and they appear to differ only in form from the different passions which accompany them. On dissection, the state of the brain does not show any appearances peculiar to melancholy, nor is the treatment which I have observed most successful different from that which is employed in mania. We every day see the most furious maniacs suddenly sink into a profound melancholy; and the most depressed and miserable objects become violent and raving.

317. The third class of Cullen is established on the assumption that a depraved condition may be present, of the assimilating or eliminating organs, without either the nervous system or the blood-vessels being primarily implicated. Such disorders, under the prevalence of the humoral pathology, were ascribed to bad humors pervading the body; a notion which Dr. Cullen has in some measure himself given into by retaining the term cachexy; but to disordered action, in the absorbent or secerning organisation, are the occurrences rather referred in the present day; and the pre-disposition to them is thought to consist in a particular susceptibility to be acted on in this portion of the frame.

318. The orders of cachexia are, marcores or emaciation; intumescentiæ or swellings; and impetigines, or those cachectic disorders which principally manifest themselves in the skin and superficies of the body.

319. Of the marcores, or emaciation, Dr. Cullen makes two kinds, the tabid and the atrophic; the one being attended with hectic fever, as a prime and peculiar accompaniment, the other being without this index of diseased state. Atrophia ought, however, in strict propriety to have been transferred to the neuroses, since the assimilating functions are supposed to be secondarily at fault in these cases of atrophic as opposed to tabid wasting, or to be dependent upon a disordered condition of the nervous system; while the tabid affections originate in some inherent or essential error in the assimilating or

secernent organs; and in these last, it is said, some indications at least of hectic disposition may for the most part be traced, as well as some intimations that a scrofulous diathesis is present. What, asks our author, is hectic? What is scrofula? and he replies to these questions in the following manner. Some individuals are so constructed, principally in reference to lymphatic organisation and susceptibility, that any cause which produces derangement, or deviation from healthy action, fastens with more facility upon this part of the frame (the lymphatic) than upon any other; and these are they, who, by common consent, are considered scrofulous—these are they moreover in whom hectic fever is soonest established, so much so, that any attentive observer may be guided in his recognition of scrofulous tendency, by the readiness which hectic manifests to start up and accompany a disorder's progress.

320. Fully marked hectic is indeed for the most part a signal that local disorganisation of a serious nature has established itself in some part of the body; and it is so general an attendant upon the suppurative process as to have led some theorists to trace its essence into reabsorption of pus, which had been poured out from the blood-vessels; but it does certainly show itself at times without any topical accompaniment, and does appear in some way or other to be especially connected with the lymphatic and secernent systems. If two children be affected simultaneously with inflammation of the brain, from the same acting cause, and one of them has more of the scrofulous diathesis about him than the other, you will in this one find a readier disposition to hydrocephalic effusion, you will find his little cheeks sooner painted by the hectic blush, and all things more rapidly tending towards a certain sort, as well as grade of disorder.

321. Fill the stomachs of two other children with food, which, both in kind and quality, shall make too large a demand upon the digestive and assimilating powers; in the one case you will have common pyrexial disturbance produced, or the infantile remittent fever of authors will be engendered; in the other you will have a knotted protuberant abdomen, a hectic circle of red on the face, emaciated limbs, and, in fact, tabes mesenterica; and why? Because in this last case the mesenteric glands, as parts of the lymphatic or lacteal system, are constitutionally obnoxious to ready derangement, and, probably, because there is not the proper absorbent process going on in the several secernents that are connected with the assimilating process; there may not merely be a deficient quantity of the biliary and pancreatic secretions, but such diminution may be accompanied by a deficient stimulant property in these secretions; besides, from the inactivity of the absorbents, the watery parts of the secretions referred to are not readily re-absorbed, and thus the duodenum receives them in too dilute a state for functional demands. The emaciation then of this child and its weakness are not induced in the same way as the weakness and want of flesh in the other. In the subjects of remittent fever, the blood vessels and nerves appear to have been more engaged with the disease, and the altogether of the morbid process has been of a different nature.

322. Of the intumescentiæ, the next order of the class, the rationale is often exceedingly obscure. When a permanent enlargement takes place of the abdomen, and we find such enlargement to be constituted by a deposit of fluid in the peritonæal cavity, we may seem to have some precise notion of the modus generandi; at any rate we are convinced that the tumefaction is occasioned by exhalation being greater than the due quantity, or the absorption less; but a tense protuberant abdomen shall often present itself, which can no otherwise be accounted for than by a secretion of air, and which protuberance shall appear and disappear in a manner as difficult to trace as in any morbid process to which the body is obnoxious. That the emphysematose, and tympanitic, and adipose, and physconic enlargements, are, however, in some sort or other dependent upon a depraved or rather deranged action in the secernent and absorbent functions, may be considered as pretty certain, and hence the propriety of their admission into this class of diseases.

323. In respect of actual dropsy, it has been just intimated that the pathology is rather more satisfactory; even here, however, opinion varies, as to the precise principle upon which the interstitial deposit is effected. Systematists have been accustomed, until very lately, to settle the account by assuming a want of due adjustment in the proportion of exhalation and absorption; and in this way connecting necessarily the idea of debility with the development of the disordered state. More recently, however, an undue accumulation of fluid, either in the cellular membrane or in any of the cavities of the body has been looked upon rather as the result of morbidly increased action—of inflammation, in fact, than of torpor, or want of excitement. In some diseases, that go under the denomination of dropsy, this assumed action has been most manifestly present, as in acute hydrocephalus, in hydrothorax succeeding to pneumonia, and in ascites to peritonæal inflammation; but it may be questioned whether we have not too precipitately changed sides with regard to hydropic pathology, and now think of action too much as before we thought too much of torpor.

324. Dropsy, says our author, appears fairly traceable to at least three sources. When you have sluggish circulation connected with, and indeed caused by, venous plethora, the overladen vessels empty themselves by means of their contiguous exhalants in a sort of percolating way; or at least without the induction of any disordered process that can justly be considered analogous to inflammation. It is this kind of dropsy that gradually supervenes upon obstructed viscera, such an obstruction causing an impediment to a free flow of blood and occasioning a remora among contiguous vessels. In this case neither are the exhalants nor the absorbents properly at fault, nor is there any inflammatory irritation causing the exudation.

325. Serous or watery accumulations at other times take place, where every thing about the patient indicates torpor, and torpor of a particular

kind, where, as it has been happily expressed by Dr. Bree, 'the last guardians of the safety of the animal œconomy give way and refuse to do the work of absorption.' In this case it would appear, that we have dropsy from direct debility.

326. Lastly, some kinds of inflammation more open or more masked (for inflammation has often existed when it has not been suspected), so implicates the arteries, which terminate by open mouths or surfaces, that they are obliged in their own defence, as it were, to throw out an extraordinary quantity of serous effusion, and occasionally something more than the mere watery portions of the vital fluid are sent through them during the hurry and commotion of the process. Even here, however, the tendency to lymphatic exudation is partly constitutional; and it will be found that, from first to last, there is more disposition to hectic production than is common to ordinary inflammation.

327. Whether a fourth cause of dropsy may be put down, viz. actual tenuity of blood brought on by hæmorrhage, as expressed by Dr. Cullen, seems, to say the least, problematical. The blood certainly may be, and often is, deficient in its due proportion of solid to serous part; but whether this constitution in itself would tend to serous effusion seems doubtful. In this, as in all parts of medical theory, we should be careful to avoid the error of looking for one principle and source of affections that may be dependent upon a multiplicity and variety of causes; and we should likewise be careful, when we reject old theories, not to suppose that the one diametrically opposed to the rejected one must be true.

328. Rickety deformity, one of the genera of the present order, it would not seem very difficult to account for. During infancy one of the main duties of the exhaling or secerning vessels is to throw down calcareous matter into the cartilages and osseous membranes, so as to form bone. See PHYSIOLOGY and BONE. But, when the blood from which the bony matter is manufactured is not duly fed with repeated supplies of well-formed chyle, the consequence is a failure in quantity and kind of deposit; or it may be that, from some vice in the re-absorbing energy, the same effect is more indirectly brought about; and, in this last case, we may have undue or irregular ossification, even when the blood abstractedly may not be in fault.

329. Of the third order in the class impetigines, scrofula is the first genus, on which some remarks have already been made. To say that scrofula consists of a peculiar condition of the lymphatic vessels and glands is not to say much in the way of exposition as to its absolute essence, but much more we cannot perhaps say without treading on hypothetical ground; to the immediate circumstances, however, connected with lymphatic and glandular derangement scrofula does not seem to confine its workings. Madness itself is often of scrofulous origin; and in this case, of course, the nervous system is unequivocally implicated in the disorder; but still, even here, there is something by which you seem convinced of the more than common connexion between the production of the malady and the derangement of those organs to which scrofula more especially appertains: you may even here, it is said, trace a tendency to hectic irritation, and the altogether of the case will tell you that the evil is of a peculiar, not of a common nature. It ought, however, to be noticed, that the scrofulous diathesis is marked by considerable variety in respect of degree. There are scarcely any individuals in Britain without exhibiting some slight tokens of its making up part of their constitutional stamina, while it is in some so conspicuously manifested as to be obvious to the most superficial observer.

330. Of syphilis, the second genus of the order impetigines, we shall not say any thing in this place, as its history, peculiarities, and treatment, will be considered in the article SURGERY. Scurvy is principally confined to marine situations and circumstances. It seems to consist of a broken down, or in some way vitiated, condition of the blood, connected for the most part both with a primary and consequential derangement in the nervous power, and is thus very different from scrofula—the one being, so to say, more sanguineous, the other more glandular or lymphatic.

331. Elephantiasis, lepra, frambœsia, and trichoma, are the four succeeding genera of this order; but as these are cutaneous complaints, and as Dr. Cullen may be considered particularly defective in his notions and arrangements of skin disorders, we shall defer any remarks on them till we come to treat especially of the ailments which affect the surface of the body. Icterus (jaundice) is also placed here, but most evidently misplaced: for that an accidental obstruction of the bile passages, causing the fluid destined for one part of the system to be thrown upon another, should be put down to the score of bad habit would seem, in every point of view, to be highly inconsistent with the principle of the classification; but it becomes more obviously and especially so when the term cachexy is meant to predicate a morbid susceptibility, or disordered excitation of the secernent, assimilating, or glandular organs.

332. Cullen's fourth class, as the reader will see by turning to the nosology, comprises local affections; there is, however, a good deal of objection to the very notion of topical as opposed to universal ailment, and it has been made a question whether the idea of locality, independent of external irritation, may not be based upon a wrong foundation, there being such an intimate and pervading connexion among the several constituents of an organised body, that the isolation thus assumed cannot be fully substantiated. In the first order of the locales, viz. the dysæsthesiæ, comprising affections of the senses from vitiated organs, as caligo, amaurosis, dyspepsia, &c., we often positively know, and may for the most part positively infer, that the local is but an accidental expression of systematic or general evil. Then, again, among the dysorexiæ or depraved appetites, with what propriety, it is asked, Can anorexia and bulimia be regarded as partial derangements, while dyspepsia is considered a universal affection, even although this last, by the admission of Cullen himself, is sometimes consequent upon a disease ipsius ventri-

culi? Our author concludes these preliminary remarks by saying that, between nymphomania and nostalgia, which are placed by Dr. Cullen in his class locales, and in immediate succession as to order, no further connexion can be traced than in their commencing letter; and upon this principle nosology and nonsense are as nearly allied. To call 'a vehement desire of revisiting our native home,' which is the definition of nostalgia, a local affection, would seem indeed totally inconsistent with any other notion than that of an obscure anticipation of organological or phrenological doctrine.

PART IV.

PRACTICE.

Class I.—Pyrexial Affections.

333. Order 1. Fevers. The general divisions, it will be observed, of the febrile order of diseases, are in the first place into intermittent and continued; the subdivisions being, of the intermittent, the tertian, quartan, and quotidian, with their several varieties and admixtures; and, of the continued, the inflammatory or synocha, the typhoid or low fever, and the synochus or mixed; to which is added in the nosology hectic fever. We shall not of course repeat the definitions which are given in the nosology, but proceed to remark generally and individually on symptoms, peculiarities, causes, diagnosis, prognosis, and modes of treatment.

334. *Symptoms of intermittents.*—Intermittent fevers are characterised by a decidedly marked cold stage, in which we find rigors, paleness, collapse, short and obstructed respiration, chattering of the teeth, trembling of the limbs, and rough or contracted skin called goose skin, with a general shrinking of the features, and a small and frequent pulse. These symptoms continue for a longer or shorter period, and are then succeeded by those of the hot stage, which however is at first of partial and irregular occurrence; and at length the heat becomes universally diffused, and is much above the standard heat of health. Fulness likewise takes the place of the previous collapse and shrinking; the pulse from being small becomes fuller and harder; pains are felt in different parts of the body and limbs; nausea and vomiting are not unfrequent; the urine is high colored, but small in quantity; the breathing is hurried; there is considerable headache and throbbing of the temples; confused perception and thought, and oftentimes delirium; the tongue now becomes covered with a white crust, and thirst prevails. After these symptoms have continued for some time a moisture breaks out on the forehead, face, and neck, which soon extends universally; and now the heat and thirst abate, the urine from being high colored and scanty comes to be more copiously discharged and to throw down a sediment, the pulse becomes more free and natural, the throbbing of the head subsides, the respiration becomes less labored, and in a word, all the functions are restored to their wonted condition. The whole of this process usually takes up from six to eight hours.

We have above remarked that the tertian, the quartan, and the quotidian, are the most frequent types, as it is expressed, of intermittent fever. By this is meant, that, in the case of the tertian, forty-eight hours elapse from the commencement of one fit of fever to the commencement of another; that the period of the quartan is seventy-two hours, and of the quotidian twenty-four. The most common type is the tertian, which is the occasion of its being marked first in the nosology: this principally occurs in the spring. The quartan, which is the most severe form of ague, usually occurs in the autumn: this has generally the cold stage the longest, while the tertian has for the most part the longest hot stage.

The subdivisions and intermixtures of types we need not, as above intimated, follow; but it is necessary to remark that, while the true intermittent or ague leaves the patient in the intervals of the fits quite free from febrile disorder, there is a form of fever which is neither properly intermittent, because it does not thus go off completely; nor properly continued, because the intervals are marked, but not with distinctness: this kind of fever authors have therefore agreed to designate remittent. It is further necessary to notice that these types of fever change, tertians and quartans become quotidians, and the quotidian falls into the remittent; and this change in the general way is rather favorable than not, inasmuch as it is for the most part from a severer to a milder form. Climate very much modifies the types and circumstances of intermittent and remittent fever, and the different seasons have likewise a considerable influence upon the types of the disorder. It is in countries where heat and moisture prevail conjunctively that the remittent form of fever is the most common.

Agues often last, if not arrested by medical treatment, for some length of time, and often terminate without producing much organic mischief; but they occasionally give rise to chronic obstructions of the viscera by their continuance, more especially of the liver and spleen, enlargements of which last organ used formerly to be well known under the denomination of ague-cakes; dropsy also is an occasional sequela of intermittent fevers; but these seem rather to be produced in an indirect way, and to follow upon primary derangement and chronic obstruction of the viscera.

335. *Causes.*—The predisposition to be affected by the exciting causes of ague are, weakness of body, whether constitutional or induced by large evacuations; unwholesome diet; long watching; exposure to the cold and damp of a night air; mental depression; and, in fine, whatever tends to debilitate or derange the frame. And it is to be observed, that this predisposition is increased by habit, that is, a person having once had the disorder is more likely afterwards to have it excited by its particular and specific source, or perhaps to fall into it in consequence of exposure to cold and damp, or subjection to circumstances which are generally regarded as merely circumstances of predisposition, but which some consider actual excitants of the disorder. We may further remark that this law of habit is different from that which applies to the continued forms of fever, especially those which manifestly acknowledge a specific poison as their

source; for the effect of these is rather to lessen than increase predisposition, an individual being much less obnoxious to their influence after having once been the subject of them. This in some cases is carried almost to the extent of complete insusceptibility to a second attack.

Respecting the actually exciting causes of intermittent fevers, or agues, we may refer to what has been advanced in our introductory remarks (see par. 290); in which it will be seen that a difference of opinion prevails on this head, some supposing that a particular poison engendered from the decomposition of marshy lands is absolutely necessary for the production of ague, or even remittent fever; while others contend that, so far from marsh miasm being necessary to the excitation of intermittent, we have no evidence that such poison ever operates, or even exists. In addition to what has been advanced on this head, we shall here beg leave to introduce the remarks of a modern and luminous writer, Dr. George Gregory, to whom we shall become more indebted for quotations and extracts as we proceed in our disquisition.

The great and important occasional cause of intermittents, says Dr. G., are the effluvia arising from marshy grounds, and called by physicians marsh miasmata. It is certainly a curious fact that this pathological principle, so obvious and so important in its practical tendency, should have been unknown, or at least unnoticed by the older medical authors. Sydenham seems to have had a glimpse of it, but he could not have seen it in its true light, for in his fifth chapter he attributes agues to the ebullition of spirits and viscid juices. Lancisci is the original writer on marsh miasmata. His treatise is entitled De Noxiis Paludum Effluviis. We are not, however, yet acquainted with all the circumstances upon which the production of ague depends. It is presumed, however, that the miasmata arise from the combination of earth and moisture with putrescent vegetable matter. Moisture alone, though ever so abundant, will not produce ague; for it is a rare disease at sea, even upon the foggy banks of Newfoundland. When the marsh is covered by water, agues are less frequent. Of the exact nature of these miasmata we are ignorant, but some points have been noticed with regard to them to which it will be proper to advert.

The most elevated parts of a marsh being always the healthiest, it is imagined that the miasmata are comparatively heavier than the atmospheric air. There is reason too to believe that they cannot be wafted by currents of air to any great distance from the spot where they were generated, but on this point some differences of opinion have lately prevailed. The calm months of the year being the most productive of agues, it is reasonable to suppose that the miasmata are most powerful when concentrated, and that diffusion by a brisk wind renders them comparatively inert. Culture and proper draining prevent their formation, and hence it is that intermittent fevers are so much less frequent in England at present than they formerly were. A very short exposure to the exhalation of a marsh is sufficient to affect the system. Travelling through the Pontine marshes has often been followed by an attack of ague. There is considerable diversity in the period which elapses between exposure to marsh miasmata, and the invasion of the disease. It sometimes does not exceed a few days, but there is reason to believe that the latent period has occasionally extended to several weeks or even months.

But, though it cannot be disputed that marsh miasmata are the most frequent and important existing causes of intermittent fevers, still it would be impossible to deny that it has others. Febrific miasmata may unquestionably arise, under particular circumstances, from almost any soil. Persons residing in very healthy parts of London are occasionally attacked by intermittent fever. In the time of Sydenham, agues were common in every part of the metropolis. To the great attention which is now paid to the sewers we are probably in a great measure indebted for the present healthiness of the town, and particularly for our exemption from ague. The occasional occurrence of the disease, therefore, at a distance from marshes, is not to be a matter of surprise. Agues prevail extensively in certain districts where there are no marshes; but then it will always be found that there is something equivalent to a marsh. There is either a subsoil of such a nature as does not allow water to penetrate easily through it; or there is a great extent of wood impeding thorough ventilation and the action of the sun's rays; or there is total inattention to drainage and culture. In one or other of these ways we may be able to explain the prevalence of ague in the uncultivated parts of America, and in many parts of Italy, particularly the neighbourhood of Rome, Naples, and Syracuse.

These peculiarities of soil are not merely the occasion of agues, but they serve to modify the characters of continued fever, and of any other febrile disease which may happen to occur in the district. They give a tendency to exacerbation and remission in the symptoms of the fever; and it is not improbable that many cases of what might be considered genuine remittent fever from marsh exhalations, are in fact cases, of common continued fever from cold modified by peculiarities of soil.

We may add that there is still much that is obscure with respect to the actually producing causes of intermittents; these forms of fevers, after having been almost unknown in the metropolis for many years, have within these few past months been comparatively frequent here; a fact which should seem inconsistent with the notion of marsh miasmata, which generally obtains: indeed there is every reason for the inference that much of disease-creating and disease-modifying circumstance has reference to atmospherical variations which have hitherto been altogether undetected excepting in their effects.

336. *Prognosis.*—In Britain, and in other countries in the north of Europe, agues are for the most part unattended with any immediate danger; but the disorder is apt, as above intimated, under unfavorable circumstances, or injudicious treatment, to give rise to visceral obstructions, and their consequences. In some parts of Africa agues are diseases themselves of great danger, without reference to their interme-

diate consequences; and in all cases we may say of the disorder, that its prognosis will be greatly regulated by climate, soil, and season. When the fits are of short duration, and regular recurrence, a speedy or an interrupted solution of the malady may be looked for; but when they are of long continuance, and accompanied with structural derangement, or even of very violent affection of function, the disorder is likely to continue for some time, and its termination in health will be doubtful.

337. *Treatment.*—The obvious indications are to abate the violence of the fit; and, when the fit has subsided, to endeavour at preventing its recurrence.

During the cold stage, warm diluent drinks may be given; warm fomentations applied to the legs and feet; or the patient may be immersed in the warm bath should the symptoms be very violent; and cordial diaphoretics may be administered.

℞ Ammoniæ subcarbonatis grs. viii.
Liquoris ammoniæ acetatis f. ʒiij.
Syrupi aurantiorum f. ʒij.
Aquæ puræ f. ℥j.
Fiat haustus.

That is, Take of subcarbonate of ammonia eight grains, liquor of acetate of ammonia three fluid drachms, syrup of orange peel two fluid drachms, water one fluid ounce for a draught.

When the hot stage is fully set in, saline and cooling medicines are called for, with acidulated drinks; and now it will be proper likewise to give diaphoretics, of which one of the best, when the irritation runs very high, is a small dose of tartarised antimony, as in the following formula:

℞ Antimonii tartarizati gr. ⅙.
Aquæ puræ f. ℥iß.
Fiat haustus.

That is, Take of tartarised antimony one-sixth of a grain, and water a fluid ounce and a half, for a draught; or a solution of half a scruple of nitre (potassæ nitras) may be administered in a draught of water; or the common saline draught, either in a state of effervescence, or when the effervescence is over. The effervescent saline draught is made by mixing a scruple of carbonate of potass (salt of tartar) dissolved in a fluid ounce of water, and sweetened by sugar, with half an ounce of lemon juice, or, what is quite as good, fifteen grains of the concrete citric acid. Some practitioners give opium in the hot stage, to the extent of from thirty to sixty drops of the tincture, about half an hour after its accession; others recommend a fluid drachm of sulphuric ether for the same purpose of shortening the fit, abating its violence, and hastening perspiration. Bleeding too has been recommended, especially where the irritation of the hot fit runs high, or the inflammatory diathesis is conspicuous. Saline purgatives may at this time also be exhibited should constipation accompany heat; and there is no better aperient on these occasions than from half an ounce to an ounce of Epsom salts (magnesiæ sulphas) dissolved in camphorated mixture. In short, the treatment of the hot stage of intermittent fevers is pretty nearly the same as the treatment of continued fever, marked by irritative or inflammatory excitement; and to heat in the cold stage, and cool in the hot stage, are the plain indications of nature. Some practitioners administer, immediately before the accession of the cold stage, an emetic, with a view of producing such an impression upon the system as to interfere with the full development of the febrile action, and some give tincture of opium at this time, with the same intention; so that it will be recollected that opium is given by different individuals, both in the cold and hot stages.

For the purpose of accomplishing the second indication, viz. preventing the disorder's recurrence, remedies are had recourse to in the intermission, and of these emetics, purgatives, Peruvian bark, arsenic, and forcible impressions made upon the nervous system, are the principal. For an emetic, a scruple of the sulphate of zinc may be given, dissolved in water; and the purgatives at this time of the apyrexia should be rather of the resinous than saline kind. A fluid ounce of the compound decoction of aloes, with the same quantity of infusion of senna, will make a good aperient draught, and when decided marks are present of obstructed viscera, or disordered condition of the alimentary and intestinal canal, mercurials may be joined with the purgatives that are administered, and by the exhibition of them the system will be better prepared for bark or arsenic. Five grains of blue pill at night, succeeded in the morning by the above-named purgative draught, and these repeated two or three times in the course of the week, will constitute a good preparative or accompaniment of bark, which given without these deobstruents, as they would be called by the Boerhaavians, might, while it cures the complaint, tend to facilitate the visceral infarctions above referred to.

Bark should for the most part be given when the system is entirely free from pyrexia; it may be administered in drachm doses every third or fourth hour, or even oftener if the stomach will bear it; so that several doses may be exhibited during the intermission; the following draught may be substituted.

℞ Extracti cinchonæ resinosi grs. xv.
Tincturæ cinchonæ compositæ f. ʒij.
Syrupi aurantiorum f. ʒi.
Decocti cinchonæ f. ℥iß.

That is, Take of extract of bark fifteen grains, compound tincture of bark two fluid drachms, syrup of orange peel one fluid drachm, decoction of bark a fluid ounce and a half; for a draught.

As an excellent substitute for bark in those large quantities, the modern concentration of it, beginning now to be well known under the name of the sulphate of quineric, may be administered with much advantage. Of this two grains may be given instead of the bark powder or draught, made into a pill with a small quantity of crumb of bread, or thick mucilage; or it may be made into a draught with water and two or three drops of the diluted sulphuric acid. The medical practitioner, who has not hitherto

been in the practice of employing this medicinal, will often be surprised at its prompt efficacy, both in intermittent fevers, and in other cases where considerable quantities of bark are indicated, but where the stomach is scarcely able to receive the necessary quantity in the form of powder, decoction, or extract. It should be observed that, when the extract of bark is employed with a view of giving the medicine in large doses, the resinous extract, or that made with spirit, is much superior to the aqueous, as by the action of the spirit a part of the bark is taken up which is not soluble in water.

When arsenic is administered to cure intermittent (which for the most part is more efficacious, at any rate, than the old forms of bark), the liquor arsenicalis of the London Pharmacopœia should be employed. This is an arseniate of potass, and often proves promptly and decidedly efficacious in preventing the recurrence of the febrile paroxysms. It may occasionally be employed with tincture of opium in the dose of five minims of the former to three or four of the latter. Under proper management, says a modern author, arsenic will be found to be the most generally useful of all the medicines which have been recommended in the treatment of agues. The best mineral substitute for it is the sulphate of zinc, which is largely employed in the fenny counties of England. It is given in doses of one or two grains three times a day, and is very highly spoken of.

A strong impression made upon the imagination of the patient will sometimes break in upon the habit of the disorder, and at once dislodge the malady, which shall have seemed reluctant to give way to the common remedies. Charms have often proved efficacious; and it is not necessary to say that their operation is upon the principle now adverted to.

While the secretions are kept in good order by the administration of purgatives and mercurials, to which, by the way, the taraxacum (dandelion) may be occasionally added with advantage; a generous diet, and the moderate use of wine, will be found requisite during the absence of the paroxysms. These too are good preventives of the malady, especially after a patient has been the subject of an attack.

Remittent fevers are to be treated upon the same general principles with intermittent and continued. These are types of fever which, as above intimated, are very common in counties where there is a combination of heat and marshy exhalations, or humid atmosphere. Their varieties, from endemial causes, and local circumstances, and constitutional peculiarities, are almost endless. They are, however, for the most part characterised by an excited or disturbed state of the biliary functions, and on this account especially call for medicines which act as an emulgent to the liver; but we shall have further to speak on this head, when considering that form of disease which has been termed yellow fever.

338. *Continued fevers.*—The student, by turning to the nosology, will perceive that Dr. Cullen's system recognises three forms of continued fever; but it will be right to take these, as all other divisions in medicine, merely as arbitrary or conventional, and to recollect that, although the definitions are as accurate as definitions can be, the practioner must expect to find endless varieties and modifications. We shall in this section, as we have done in that devoted to intermittents, first treat of the general symptoms of fever, then of their causes, prognoses, diagnoses, and management.

Symptoms of continued fever.—Lassitude, languor, and anxiety, followed by rigors, which are again succeeded by partial, and at length universal, heat; indeed, the history of a paroxysm of intermittent fever is, in some sort, a description of continued fever; but, for the most part, there is in these last more of animal depression and sensorial disturbance than is the case in intermittent fever. A very great prostration of strength also, in the general way, marks the commencement of continued fever, though in respect to the degree of this symptom there is found very great variety; and in some cases the powers seem rather obstructed or oppressed than actually exhausted; indeed, this particular may be received as one of the differences between positive debility and the peculiar debility of fever—that in the latter there is an indisposition to exert power—while in the former there is the inclination without the ability. The pulse in fever becomes more frequent than in health, and it wants also the freedom of health; it is oppressed, and if the fever be what is called inflammatory, or marked from the onset by very high excitement of the vascular system, there can be recognised a hardness as well as obstruction about its beats; this hardness, however, is more conspicuous when the fever is what is called symptomatic, that is dependent upon actual inflammation of some one organ. It should be observed that the symptoms of continued fever, especially of the fevers that are met with in this country, are often of gradual and almost imperceptible invasion. You cannot always draw the line of demarcation between health and disease; the patient is often unwell rather than positively ill for some days; and the young and inexperienced practitioner must not condemn himself for being less skilful and observant than others, should he fail to anticipate the full formation of unequivocal fever, from having seen the patient during the time and circumstances now referred to. When, however, there is continued languor and depression, especially if it be attended with confusion of thought and general difference of perception from what is the case in health—when these symptoms are accompanied by an altered state of pulse, by pains of an obscure and wandering kind about the limbs, by sighing, or hurried or obstructed breathing, by a peculiarity in the expression of the countenance, especially of the eye, this last organ being sometimes dull and dim, at other times morbidly sensible to the light; and the vessels of the tunica conjunctiva injected with red blood—when in addition to these symptoms the tongue becomes furred, the skin hot, shrivelly, and dry, the urine scanty and high colored, and the bowels torpid or irregular, we may be pretty certain that fever is about to establish itself; and

the particular nature of the fever will be usually designated by the prominence of one or two characteristic marks; thus in the plague, which according to Dr. Cullen's classification would be a typhus gravior, the most marked of all the early symptoms is the extreme prostration of the strength, and the staggering of the individual attacked, and in the course of the malady buboes become its characteristic; while, in the yellow fever of the West Indies, typhus icterodes, the yellow color of the skin, the buboes, derangement, and the black vomit, are the prominent features of the distemper.

339. *Causes of continued fever.*—On this head we must refer to our proem, as we did in the case of intermittent fever, where it will be seen that a difference of opinion still prevails on the excitants of the febrile state, one party supposing that no case of genuine fever of any continuance can have place without the operation and influence of a certain morbific poison which is peculiar to itself; another going to the opposite extreme of supposing that contagion is a mere imaginary power, and, while it is supposed to operate so as to communicate the malady, that the communication has, in point of fact, been from the air and circumstances of the place; while a third, and moderate party, think that we have sufficient evidence for the existence and operation of a poison in fever, but that the action of this poison is not, so to say, abstract and exclusive, that is, does not display its effects independently of the soil and atmosphere, and other circumstances of place, and that the disorders themselves, in which this poison is engendered, and by which they are propagated, may originate at times spontaneously. All parties, indeed, acknowledge that some distempers are directly and absolutely dependent upon a specifically exciting cause, and the disputes in some measure resolve themselves into the extent or limitation of this specific causation; whether, for instance, the plague of the Levant, and the yellow fever of the West Indies, originate and are communicable in the same manner as are small pox and measles.

As considerable importance is attached to this enquiry, we shall in the present place add to the remarks made in the preliminary portion of the present article, the following quotation from Dr. Gregory, which, in our judgment, contains as clear and distinct an account of the subject in dispute as any we have met with. After speaking of cold and atmospheric alternations of temperature as causes of the febrile state, Dr. Gregory, the author to whom we now refer, goes on to say—'Continued fever, however, has another and a very important exciting cause, which frequently operates where neither cold nor alternations of atmospheric temperature can be suspected, as where fever attacks persons shut up in close rooms with others laboring under the disease. When fever appears under such circumstances, it is said to have its origin in contagion.' A number of the most important doctrines in the science of pathology are closely associated with the subject of contagion. From the earliest periods at which it became an object of enquiry this has been acknowledged, but the investigation is obscure and difficult, and has proved a source of endless controversy. Many of the disputed points in medicine are interesting only to the man of science, but the doctrines of contagion are of general interest, because involving practical considerations of the highest importance. Without attempting to clear up all the difficulties in the way of the enquiry, I shall be satisfied with a brief enumeration of its leading positions, and of the principal points in dispute.

1. Attempts have been made to throw discredit on the doctrine of contagion as the cause of fever, by showing that it was for a long time either unknown to or discredited by physicians. It is certainly a curious fact that, for the first dawnings of information concerning it, we are indebted, not to Hippocrates or Galen, but to ancient poets and historians. Thucydides, in his account of the epidemic fever or plague that raged in Athens during the Peloponnesian war, shows that he understood contagion in the sense in which we now use the term; noxious matter from one body producing a similar disease in another. In Plutarch's life of Pericles, we read that, whilst that commander was laying siege to the city of Epidaurus, a distemper prevailed in his army, which not only carried off his own men, but all that had intercourse with them. Livy, in the account of a camp fever which affected the armies of the Romans and Carthaginians at the siege of Syracuse, distinctly states that it was propagated by contagion:—'Postea curatio ipsa et contactus ægrorum vulgabat morbos.'

Virgil and Lucretius employ the term contagion to express the manner in which a disease of sheep spread among the flock. Medical writers were for the most part very inattentive to contagion, until the time of Sydenham, in whose work (sect. ii. cap. 2), a distinct reference to contagion may be met with. Boerhaave and the followers of his school were very incredulous on the subject of contagion. Their ideas about it too were very imperfect and confused, from the circumstance of blending the notion of contagion with that of marsh miasmata. Dr. Huxham, Dr. Lind, and Sir John Pringle, are the great original writers on contagion, particularly on that of continued fever. Since their time the subject has undergone the most rigid examination, and, as we have said, has given rise to the most discordant opinions.

2. Much confusion has been introduced into the subject of contagion by the employment of the term infection, and by the different acceptations in which contagion and infection have been taken. This has been increased from the want of proper attention to the distinction between common contagion and specific contagion. Of this last kind are small-pox, measles, the plague, and syphilis. Diseases which, occasionally produced by contagion, are yet sometimes owing to the operation of other causes, are said to arise from common contagion; of this kind are catarrh, erysipelas, ophthalmia, and typhus. The laws of common and specific contagion are in many respects similar, but they have also their points of difference.

3. In the last paragraph, that has been as-

sumed as an established principle, which has been and still is made the subject of keen dispute, viz. that typhus fever does originate from contagion, and that it is of the kind which we have called common in opposition to specific contagion. Both those points have been called in question. By a few, and happily a very few, it has been contended that the notion of a contagious origin of typhus fever is altogether unwarranted; but the views of these anti-contagionists are so completely at variance with the generally received opinions of medical men, and so irreconcileable with facts obvious to all mankind, that any formal refutation of them is unnecessary. On the other hand there have been, and there continue to be, physicians who believe in the exclusive origin of typhus from contagion, who maintain that no disease can propagate itself by contagion, which had not its own origin in contagion; in other words, who deny that common continued fever under any the most adverse circumstances can ever spread by contagion. This opinion involves the difficult, but for the most part idle question, how contagious fevers are originated; but, setting this aside, it may fairly be argued, that it is neither borne out by observation nor by reasoning. There is nothing improbable in the supposition that what originated in cold may be afterwards propagated by contagion. It violates no established law of the animal economy. Experience, on the other hand, appears to favor it; and it may therefore be laid down as an important practical principle, that fever which originates in the first instance from common causes, may, under certain circumstances either of local situation or constitution of body, spread by contagion. What these particular circumstances are may be imagined from what has already been said. The principal of them are crowded and ill-ventilated apartments, want of cleanliness and comfort, a close and sultry state of the atmosphere, and previous weakness of the affected individual, whether owing to excessive fatigue, or an improper or scanty diet.

4. Many of the controverted points in the doctrine of contagion hinge upon this question, but there is another of almost equal importance involved in their decision. Sydenham long ago argued it with much force of argument, and a due attention to his observations might have prevented much of the controversy which has lately taken place on the subject of the plague and yellow fever; I mean that particular constitution of the atmosphere which disposes to, or which checks the diffusion of febrile contagion. A malignant contagious disease, when once it has got footing in a populous city or district, does not go on to the destruction of all the inhabitants. Several circumstances contribute to this: first, peculiarities of constitution, which occasionally secure an individual completely from the influence of contagion; secondly, the immunity from future attacks, which, in several instances of febrile contagious diseases, is afforded by its having been once undergone.

These two circumstances certainly contribute to explain the fact just mentioned, but they are not fully adequate to the effect. A certain constitution of the air, therefore, sometimes favoring, but sometimes checking, the diffusion of contagion, must be admitted as a third general principle upon which it depends. Some physicians have pretended to find fault with this multiplication of causes for explaining a single phenomenon, and have argued that a peculiar, or, as Sydenham says, an epidemic constitution of the air, is alone capable of explaining what others refer to the combined operation of it, and of the principle of contagion. As well might they argue that the tree could be reared without the seed, because a peculiar condition of soil is required for its reception and growth. Several of the most important facts in the histories of great epidemics, particularly the plague, will hereafter be illustrated by a reference to these fundamental doctrines in the laws of contagion.

5. Much speculation has taken place among medical authors, regarding the mode in which contagion produces its effects in the animal economy. It has been observed, of a number of diseases notoriously arising from contagion, that they exhibit even from an early period symptoms of great depression of nervous energy, or of collapse. This is exemplified in the cases of plague-typhus, cynanche maligna, influenza, erysipelas; and it has been imagined that there is in the nature of contagion something which is directly sedative or depressing of the nervous energy. A more extended view of disease would show the fallacy of this as a general principle. Measles and ophthalmy, which yet exhibit all the marks of genuine inflammatory excitement, are diseases as obviously arising from contagion as plague or typhus. The operation of contagion may possibly be upon the brain and nerves, but its precise effect upon them is altogether inscrutable. Still, while a caution is offered against assuming as a principle of pathology any thing sedative in the nature of contagion, we must be insensible to the importance of the fact, that cases of disease arising from common contagion, above all continued fevers, are more likely to be of the low typhoid kind, than such as are attributable to cold, or other causes independent of contagion.

6. Of the intimate nature of the contagious particles which arise from morbid bodies, and which produce a like disease in others, we know nothing; but there are a few particulars concerning them which are known, or conjectured, which it will be proper to notice.

Great attention has been paid by Dr. Haygarth and others to determine the distance to which the noxious effluvia extend, and at which they operate in exciting disease. There is reason to believe that this varies in different cases, and that the plague, typhus, and small-pox, have in this respect each their respective laws. The subject, however, does not appear to have been yet investigated with sufficient accuracy to enable us to lay down any established points of doctrine with regard to it. It is not, for instance, known how far the sphere of contagious influence is affected by ventilation. In the case of continued fever, we are warranted in saying that a free circulation of a pure and cool air renders the contagious particles comparatively inert, even if it does not altogether prevent their formation. Some physicians have extended their views fur-

ther, and have maintained that there are certain chemical substances that have the power of decomposing contagious effluvia, or at least of rendering them in some way or other innoxious; of these the principal are acid vapors, particularly those of the nitric and acetic acid, and chlorine. Fumigation has therefore been recommended as a powerful means of counteracting contagion. The theory upon which it has been introduced is exceedingly doubtful, and the practice, far from being generally applicable; acid vapors of all kinds being more or less injurious to breathing. If fumigation is adopted as a substitute for thorough ventilation it may prove injurious: if only superadded, it is perhaps superfluous; but, on a point of such practical importance, it is right to speak with much caution.

The next subject of enquiry which the general doctrine of contagion offers is the attachment of contagious particles to certain bodies, thence called fomites, where they may lurk for a very long period of time and subsequently renew the disease with all its former and even increased virulence. It is the most curious fact in the history of contagion, and one established upon the most unquestionable evidence. The principle appears to be of more general application than any other which the doctrine of contagion involves. The plague and typhus, small-pox and scarlet fever, ophthalmia and porrigo, afford the most familiar illustrations of it; but it is doubtful if there is any species of contagious disease which may not be communicated through the medium of fomites. They may either be hard or soft bodies. The walls and wainscoting of the room, the bed and bed-furniture, the furniture of the rooms, and the clothes of the patient, are those against which we are to be chiefly on our guard.

It is well ascertained that the clothes of an individual, who is himself unsusceptible of the disease, may become the fomites of its contagion. In this manner typhus, small-pox, and plague, are not unfrequently disseminated.

Attempts have been made to ascertain the period of different diseases at which their contagion is most active, and that at which the body ceases to afford contagious matter. This point it would be of much importance to determine, as it would indicate when a patient might safely be permitted to mix in society; but unfortunately there do not appear to be sufficient data to enable us to decide the question with any degree of accuracy.

340. *Prognosis in continued fevers.*—The favorable symptoms in fever are in the first place the pulse not mounting very high above the ordinary standard in respect of numbers. Dr. Heberden, whose opinion of the pulse was different from many others, and who thought that very little notice need be taken of it beyond that of its greater or less frequency, considered that there was always something to be apprehended if the pulse continued regularly at more than 100 beats in the minute; and although many patients recover whose pulse, from first almost to last, is much higher than this; and, although the mode as well as the number of pulsations seems to demand somewhat more of recognition than Dr. Heberden was disposed to admit, we should say that it certainly is an unpleasant and an unfavorable circumstance in fever to find the arterial beats steadily above 100. It must always, however, be taken into account that much depends upon the constitutional proportion of healthy pulse in the individual affected; scarcely is it necessary to say that if the subject of fever has had, while in health, an average pulse of from eighty to ninety in a minute, the increase to 100 in him is not of such unfavorable import as had the natural pulse been only seventy. Another favorable circumstance is the absence of hardness, or wiryness, or obstruction, in the pulse; for, when these conditions of the arterial beats are present and prominent, they denote both an indisposition in the febrile state to give way, and are often likewise marks that some internal organs are more especially engaged with the disordered condition; hardness of pulse generally indicating local inflammation, while obstruction, and want of freedom in the beats, points out, perhaps, an unequal circulation, and a gorged or congested state of some parts of the system. We make use of the word, perhaps, because there is some degree of hypothetical inference in the idea of congestion, as opposed to inflammation, and because some pathologists will not allow the presence of fever without the presence at the same time of inflammation. At any rate a soft and free pulse, as well as one of less morbid frequency, is a good symptom. Respiration, from having been oppressed and hurried, and obstructed, becoming free, is likewise a favorable sign. The urine depositing a large sediment looks well; the tongue becoming moist at its edges is a favorable indication. Warm and general perspiration, as opposed to partial and irregular sweats, are good. Local tendencies in the fever, such as breakings out about the mouth, are often favorable symptoms; the countenance remaining unchanged argues well, as also does, more especially, the absence of delirium; the position of the body is also of importance to attend to; for, if it does not much change from that of health generally, there is room, as far as this particular is concerned, for hoping a favorable termination. Deafness has been considered a favorable sign, especially in fevers of a low or typhoid character; and, though it may be difficult to say why it should be, there does seem to be some foundation for the belief.

The unfavorable symptoms, it is scarcely necessary to say, are positive and negative, the absence of good being the presence of bad; but there are some degrees which are of unequivocal and positive kind, and which in proportion to their extent and degree denote danger. Much delirium, whether of the high phrenetic kind, or of the low muttering cast, is an exceedingly bad sign in fever, as it denotes a great deal of general derangement, and often points out a considerable extent of cerebral affection; hurried and laborious respiration is also bad, whether the derangement be merely functional, or whether it be attended with marks of pulmonary inflammation, or obstruction; on one account, indeed, the former species of respiratory disorder is the worst, inasmuch as it implies a great extent of general disorder. What authors call subsultus tendinum is always considered a bad omen; it is that invo-

luntary twitching and motion among the tendons and muscles, particularly about the wrist, which you often witness, and which manifests a great deficiency of muscular, and therefore of nervous, power. A picking about the bed-clothes, as if to remove something that offends the eye, is a bad omen; it shows the brain and the perception to be in a state of considerable derangement, and the degree of danger is often dependent upon the measure of cerebral disturbance. A very great prostration of power marked by lying on the back, rather than on the side as in health, and by sliding gradually down to the foot of the bed is one of the bad omens in fever. A collapse and sharpness of feature is proverbially so. An indisposition or incapacity of putting out the tongue when the patient is requested to do so is always unfavorable, as it denotes either want of power, or want of consciousness, or a mixture of both; the tongue being covered with a thick black border may be also taken as an unfavorable symptom; a tense, drummy, or unequal, feel of the abdomen, in place of a soft and yielding condition of it, looks ill; this mark, with several others here noticed, will be found in the historical part of the present article as generally a bad indication of disorder, noticed by Hippocrates, and it is always highly worthy of observation; fœtid excretions and intestinal evacuations of a very offensive odor prove a considerable derangement in the assimilating and chylopoietic functions; and when the urine and fæces pass involuntarily the danger must be considered as extreme; a cadaverous smell of the body argues very ill; as well as other indications of what has been called a putrescent tendency, 'a state of body,' says Dr. Gregory, 'the notion of which has in later times been the frequent subject of dispute.' 'That the powers of the living body, in checking the putrescent tendency of all animal matter, should be diminished in certain states of disease does not,' our author very properly remarks, 'appear to be an unreasonable supposition.' The following may be enumerated as the chief symptoms which mark the putrescent diathesis. A loose or very imperfect coagulation of blood; fœtor of the evacuations; a squalid appearance of the skin, and a cadaverous odor of the body; hæmorrhages from the mouth, nose, stomach, rectum, or urethra; the blood being of a very loose texture and quickly putrefying; petechiæ and vibices; a disposition to gangrene in the skin wherever it has been accidentally wounded, or abraded, or exposed to long pressure; the speedy putrefaction of the body after death. 'It would,' Dr. G. continues, 'be necessary to clear up many of the difficulties in which the doctrine of the coagulation of blood is involved before we could arrive at a satisfactory explanation of these phenomena; but, in the mean time, there are sufficient grounds for believing that they depend in a great measure on the deranged functions of the brain. Petechiæ, or tumid spots, appearing on the skin are a very bad omen, inasmuch as with extreme debility they indicate a loose crasis of the blood; this circumstance of petechial eruptions Dr. Cullen makes of sufficient importance to found a species of disease upon; for under the genus typhus the student will see one of the species petechialis spotted fever; the other, icterodes, yellow fever. Petechiæ would seem, for the most part, to be mere accidental indices of extreme weakness connected with morbid activity, and, as above intimated, a loose texture of the blood.

We may add to the above enumeration of unfavorable symptoms a coldness in the breath, which shall be perceived by the hand being placed before the mouth of the individual laboring under fever. Aphthæ, too, about the mouth and fauces, are bad symptoms; they in general mark both extreme weakness and the simultaneous presence of a low inflammatory action about the mucous linings of the first passages.

'The general prognosis in continued fever is certainly favorable. Under proper management a large proportion of cases recover. This is a point which has been made an object of enquiry by different writers, and a very curious coincidence has been traced in the extent of mortality occasioned by continued fever, under circumstances considerably different. The average of deaths in the hospitals of this country appears to be in the ratio of about one to twelve, which is believed to be considerably below the ordinary scale of the mortality of fever, when it occurs in private habitations, even with access to medical assistance. It varies, of course, with the general character of the epidemic, the period of the disease at which it is first submitted to medical treatment, and many other circumstances of nearly equal importance.' A pamphlet was some time since published by a Dr. Brown of Edinburgh (not the celebrated author of the Elementa, to whom reference will be found in another part of the present article), in which it was endeavoured to be proved, that the rate of mortality from fever is the same generally, whatever plan of treatment may be pursued. The object of the writer was to show that no system of remedial management is available in lessening the mortality of the disorder, and that treatment or no treatment amounts in the end, or in the long run, to the same thing. We must refer to the preface of Dr. Young's work on medical literature for a refutation of this position, in which Dr. Y. makes out that the author to whom we have alluded, although ingenious in his arguments, and specious in his inferences, has completely failed in substantiating his assumptions.

341. *Critical days?*—We mark these, says Dr. Uwins, in his Compendium of Medicine, interrogatively, because they are doubtful. One fact, however, appears to be pretty generally admitted, viz. that all fevers are disposed to assume progressively the quotidian, tertian, and quartan type, so that, after the disorder shall have lasted some time, two whole days shall intervene between the terminating tendency, as the 14th, 17th, and 20th. Even here, however, there arises a difficulty, some considering the 21st, others the 20th, the critical day. It is probable that fevers with us are different in respect of crisis from what they were with the ancients. Dr. Gregory says the doctrine of critical days in fever, that is to say the supposition that febrile

diseases are disposed to terminate favorably or unfavorably at certain periods of the disease, more than at others, has found many advocates and some opposers, even from the earliest times. The very general reception which it has met with among mankind makes us unwilling to distrust it altogether; and, if we bear in mind how many circumstances may contribute to disturb the regular course of the disease, we may admit the doctrine of critical days in fever, without much risk of error. There has been some dispute about the precise days, but they are generally set down as the 7th, 9th, 11th, 14th, 17th, and 21st, counting from the invasion of the cold fit. It is seldom that these observations can be verified in the fevers of this country, which run their course with much less regularity than those of warmer climates.

As this doctrine of critical days is thus still a somewhat uncertain, and, at any rate, a disputed point, we shall further extract the remarks on the subject that are found in Dr. Good's Study of Medicine. Dr. G. discusses the question with much ability and candor.

'A sudden and considerable variation of any kind, whether favorable or unfavorable, occurring in the course of the general disease, and producing an influence on its character, is still loosely expressed by the name of crisis. The term is Greek, and pathologically imports a separation, secretion, or excretion of something from the body; which was in truth the meaning ascribed to it when first employed, agreeably to the hypothesis of concoction which has been considered. The original hypothesis is abandoned, but the term is still continued in the sense now offered.

That changes of this kind are perpetually occurring, in the progress of continued fevers, must I think be admitted by every considerate and experienced practitioner. Nothing is more common than to behold a patient suddenly and unexpectedly grow decidedly better or worse in the progress of a fever of almost any kind, and pass on rapidly towards a successful or an unsuccessful termination.

But the important question is, whether there be any particular periods in the progress of a fever in which such changes may be expected? Hippocrates conceived there were; he endeavoured to point out and distinguish them by the name of critical days. Asclepiades and Celsus denied the existence of such periods, and the same diversity of opinion has prevailed in modern times.

It is not very easy to determine upon the subject in the present day, and especially in our own country. For, first, fever like many other complaints may have undergone some change in its progress from a like change in the nature of its remote causes, or in the constitution of man. And next it seems to be generally allowed that sudden transitions, whether regular or irregular, are more apt to take place, in almost all diseases, in warm than in cold climates. On these grounds it is probably a subject that will never become of great practical importance at home. Yet it is well worthy attention as a question of history, and which may yet be of great importance to many parts of the world

If we examine the phenomena of the animal economy, as they occur in a natural series, we shall find that they are almost in every instance governed by a periodical revolution. A man in a state of health and regular habits generally becomes exhausted of sensorial power within a given period of time, and requires a periodical succession of rest; his appetite requires a periodical supply, and his intestines a periodical evacuation. This tendency equally accompanies, and even haunts him in disease; he cannot disengage himself. Gout, rheumatism, mania, rapidly and pertinaciously establish to themselves periods of return. The hæmorrhoidal discharge often does this, and the catamenia constantly. The same occurs in fevers, but especially in intermittents; for the quotidian, the tertian, and the quartan, have upon the whole very exact revolutions. And though accidental circumstances may occasionally produce a considerable influence on every one of these facts, whether morbid or natural, the tendency to a revolutionary course is clear and unquestionable.

Now, although Hippocrates has not appealed to this reasoning, it forms a foundation for his observations; and when stript of the perplexities that encumber his writings on this subject, partly produced by erroneous transcripts, and in a few instances, perhaps, by his own irresistible attachment to the Pythagorean hypothesis of numbers, he may be regarded as laying down the following as critical days of continued fever: the 3d, 5th, 7th, 9th, 11th, 14th, 17th, 20th, beyond which it is not worth while to follow the series, for it is not often that they extend further.

In other parts of his works he regards also the 4th and 6th, and even the 21st, as critical days, so that, in the first week, every day after the disease has fully established itself evinces a disposition to a serious change, in the second week every other day, and in the third week every third day. It is not easy to determine why the 21st day should be a critical day as well as the 20th. Various conjectures have been offered upon the subject; by some it has been regarded as a mistake in the Greek copy, and by others as a piece of favoritism in Hippocrates for this number, in consequence of its being an imperfect one in the Pythagorean philosophy, as the commencement of a septenary.

De Haen, with rigid and patient assiduity, has put Hippocrates to the test upon these data: for he has accurately analysed Hippocrates' own journal of the numerous cases of fever he has most industriously collected and recorded, and finds the positions in most instances to be strictly justified; and that, out of 168 terminations of fever, not less than 107, or more than two-thirds, happened on the days denominated critical, not reckoning the 4th, 6th, or 21st, and that the 4th and 6th were very frequently critical. There are a few anomalies, but it is not necessary to notice them, because they are easily referrible to accidental causes, similar to those that retard or accelerate the paroxysm of intermittent fevers.

Now, admitting the Hippocratic table to be true, the continued fever, in its progress, is mea-

sured by the various types exhibited by intermittent fevers. Thus the quotidian prevails through the first seven days; there is on each day a slight exacerbation, and no one day is more critical than any other. After this period the tertian type commences, and runs through the ensuing week; the principal changes occur on the ninth and eleventh days, and would occur on the thirteenth but that the quartan type now assumes its prerogative; and the principal transitions, after the eleventh, take place on the fourteenth, instead of the thirteenth, the seventeenth, and the twentieth. Dr. Cullen, who has examined this subject with great attention, and simplified it from many of its difficulties, directly asserts that his own experience coincides with the critical days of Hippocrates; and Dr. Fordyce, who scarcely does justice to Cullen in other points, unites with him upon the present, and justly compliments him upon his ingenious examination and explanation of the Greek distribution of critical days. It is nevertheless admitted on all hands, that the order of succession is far less distinct, as well as less regular, in cold than in warm climates; and that it requires a thoroughly attentive and practised eye to notice these changes in our own country, or indeed in any part of northern Europe. And hence Craanen says it is lost time to look for them; Stoll that they are only to be found in inflammatory fevers; and Le Roy that the supposed critical days have no influence, and can lead to no prognosis or peculiarity of practice. Why the first week of a fever should incline to a quotidian type rather than a tertian, or the second to a tertian rather than to a quartan, we know no more than we do why fevers should ever intermit, or at any time observe the distinctions of different types. We are in total ignorance upon all these subjects. We see, moreover, that intermittent fevers, whether quotidian, tertian, or quartan, have their paroxysms recur regularly in the day time; the quotidian in the morning, the tertian at noon, and the quartan in the afternoon; and that in no instance do the paroxysms take place at night; and we see also that in continued fevers the exacerbations uniformly take place later in the day than the paroxysms of the latest intermittent; for these rarely occur earlier than between five and six o'clock in the evening, while the paroxysms in the quartan return commonly before five. Of these interesting and curious scenes we are spectators; but we are nothing more; for we are not admitted to the machinery behind the curtains.

By some pathologists the source of these phenomena is sought for in the influence of the heavenly bodies, and especially in those of the sun and moon. In ancient times these luminaries were supposed to produce an effect on all diseases, and especially on mania, epilepsy, catamenia, and pregnancy. And when the Newtonian philosophy first illuminated mankind with the brilliant doctrine of universal attraction, Dr. Mead stepped forth into the arena and revived and supported the ancient doctrine with great learning and ingenuity. And, as an ingenious conjecture and possible fact, of which no practical use could be made, it was contemplated till towards the close of the last century; about which time Dr. Darwin, by interweaving it with his new hypothesis, once more endeavoured to raise it into popular notice, and give it an air of serious importance. Dr. Balfour of British India, however, has still more lately brought it forward as a doctrine capable of direct proof, and as peculiarly affecting the progress of fevers. His opinion, which he endeavours to support by weighty facts and arguments, is, that the influence of the sun and the moon, when in a state of conjunction which is named sol-lunar influence, produces paroxysms or exacerbations in continued fever, in all cases in which a paroxysmal diathesis (for such is his expression) exists; and as this influence declines, in consequence of the gradual separation of these luminaries from each other, and their getting into a state of opposition, a way is left open to the system for a critical and beneficial change, which is sure to take place, provided the critical disposition is at this time matured. In other words, paroxysms and exacerbations in fever may be expected to take place (and do in fact take place) at spring tides, and crises at neap tides.

This is a new view of the influence of the heavenly bodies upon the human frame, and a view which, though feebly supported by facts, is advanced with all the dogmatism of an established science. There is nevertheless more in medical astrology than is perhaps generally supposed; it is an important branch of meteorology, and, as such, is well worth studying. Nor can there, I think, be a question in any impartial mind, that, under certain circumstances, and especially in tropical climates, many diseases are influenced by lunation, as we are sure they are in all climates by insolation. The concurrent observation of a host of candid and attentive pathologists, who have been witnesses of what they relate, are sufficient to impress us with this belief; but, till we know more fully what these circumstances are, we cannot avail ourselves of their remarks, and can only treasure them up as so many isolated facts. And hence it is that in no age or country whatever has the study been turned to any practical advantage, expedited the cure of a disease, or enabled us to transform the type or interval of one kind of fever into that of another. Nor is it any exclusive reproach to the art of medicine that it should be so; for, of all the subdivisions of general philosophy, there is none so little entitled to the name of a science as meteorology itself. And, till the naturalist has explained the variations of the barometer, the physician need not blush at being incapable of turning to account the supposed influence of the planets, or of unfolding the origin, or tracing the capricious courses, of epidemics and pestilences.'

342. *Treatment of continued fevers.*—In considering the treatment of fever we may state that three indications present themselves.

Indication 1st. To excite such an action in the system as that the febrile concatenations shall be broken in upon before they may have had time to become confirmed into a habit; in other words, and according to the expression of some authors, to cut short the disease. Whether we

are able to effect this purpose at any time, and in any way, has been considered by some more than doubtful; but there should seem sufficient evidence for the great probability, at least, in some instances, of the interference of art in a forcible way, and by modes immediately to be mentioned, being available to the fulfilment of the indication proposed, provided the attempt be made sufficiently early; it would appear however as certain that fever is not properly cured in any other way, and that, should we fail of thus early crushing the nascent malady, we must be contented afterwards to follow the second and the third indication.

Indication the 2nd, being to moderate excitement, and diminish heat; to subdue inflammatory incidents, equalize the circulation, and open the secretions.

Indication the 3d.—To keep watch, as it were, over the powers of the system, and, in cases of more than ordinary sinking, to sustain the falling powers. Dr. Cullen has been ridiculed for talking of obviating the tendency of death, inasmuch it is said as all remedial agency, at all times, and under all circumstances, resolves itself into this principle; but in a disorder open to such constant changes, and incidental occurrences, as fever, there is an especial propriety in recognising the necessity of constant vigilance upon the ground now alluded to.

The first indication, viz. that of cutting short fever, has been proposed to be accomplished by large blood lettings; by dashing cold water over the naked body of the patient; by administering emetics; by drastic purgatives; or by mental impulse or agitation. When the fever is of an inflammatory type, with what in Brown's language would be called a sthenic diathesis, considerable detractions of blood at the commencement of fever, that is during the fulness of heat and excitement, will often be found of very essential service in moderating its violence, if not of strangling its birth. This practice cannot however be adopted with safety in all kinds of fevers, and even in some where the measure of excitement or irritation would seem to warrant the practice, the constitution of the air, or some exterior or interior circumstance, may render the expedient dangerous; and we should recollect, that if we go beyond the right point of reduction, without succeeding in crushing the malady, we may induce a weakness which will tend to make the patient less capable of grappling with the subsequent disorder. We may be told, perhaps, that the weak often get through fever under which the strong and robust give way; but, even allowing there may be some truth in this position, and some rectitude in the inference which may be drawn from it favorable to depleting and debilitating measures, we ought ever to recollect that natural feebleness, and that brought on by artificial means, are very different, and that it always behoves the physician to be careful, while he is destroying the complaint, not at the same time to destroy the subject of the complaint.

In the fevers of tropical climates the vi et armis plan of treatment is often imperiously, and at all hazards demanded, but for the most part disorders with us do not take on ab origine such a formidable aspect, neither do they demand or admit of such forcibly opposing measures; for ourselves then we should hesitate in the general way about joining in the recommendation of very large detractions of blood in the onset of fever, by way of laying the patient prostrate, and crushing the nascent malady; at the same time it has seemed to us that small blood-letting, say to the amount of ten or twelve ounces, in the onset of a fever which is marked by much arterial excitement and tendency to topical disorder, does considerable good by checking this tendency, and by keeping the malady from mounting up to a malignant height.

With respect to the second measure above mentioned, of cutting short the progress of continued fever, viz. that of dashing cold water on the surface of the body, we are also somewhat doubtful as to its efficacy in this point of view; but we are convinced that it may be made very serviceable in mitigating the force of the disorder, and assisting to conduct the patient through its course. We shall immediately speak of this practice more in detail when upon the subject of the second indication of remedial treatment.

The exciting cause of some fevers, when the predisposition is considerable, may have been taking into the stomach some material which either by its quantity or quality has thus proved deleterious. In this case, especially, emetics would appear to be indicated as arresting remedies, and the course of fever may occasionally be stopped both by the administration of them and of the more drastic kind of purgatives; such particularly as elaterium, which, besides procuring intestinal evacuations, so influences the whole frame as to counteract the febrile tendency. When emetics are employed with this view, viz. that of cutting short fever, they should consist in the general way of ipecacuan and anatomy combined, since this combination has a tendency to promote the secretions of the surface and thus to equalise the circulation.

℞ Pulveris ipecacuanhæ ℈j.
Antimonii tartarizati gr. i.
Fiat pulv. emeticus.

Take a scruple of ipecacuan powder and a grain of tartarised antimony (tartar emetic); mix them for an emetic powder.

℞ Vini ipecacuanhæ f. ʒij.
Antimonii tartarizati gr. i.
Aquæ puræ ʒx.
Fiat haustus emeticus.

Take two fluid drachms of ipecacuan wine, one grain of tartarised antimony, and ten fluid drachms of water; mix them for an emetic draught.

The elaterium may be given in the dose of one grain, and in the form of pill, either made up with a little aromatic confection or crumb of bread: or five grains of calomel, with fifteen of compound scammony powder, may be administered as a drastic purgative, or any other of the resinous and active cathartics; for from this the resinous class of medicines should the purgatives be now chosen, while when the fever has established itself, and you are desirous of combining

the agency of refrigerating medicinal with that of aperients, the saline purgatives are for the most part to be preferred.

Indication 2nd. Blood-letting, cold effusion; or ablution, purgatives, diaphoretics, diuretics, and refrigerants, are (says an author whom we profess a good deal to follow in the present disquisition), now resorted to upon different principles, and are to be employed with more or less freedom and frequency, as the excitement and heat are high, the powers vigorous, and the tendency to local inflammation or congestion great. When topical affections are urgent, at the same time that the vital powers are low, leeches and cupping near the affected part are to be preferred to general bleeding. It ought, however, always to be recollected, that it is rather smothered or obstructed strength that we have to deal with in fever, than actual or positive debility; and that the moderate use of the lancet, in cases calling for its employment, may for the most part be resorted to in the early stages of the disease without fear of consequences; some fevers, however, will be found not to bear bleeding, even though excitement and power seem considerable; and authors in their directions respecting venæsections are too apt to overlook very frequent exceptions to general rules. Endemic and epidemic peculiarities ought always to be carefully appreciated by the physician. For months together at times, and without any external circumstances to explain the reason, fevers demand a different treatment from what may be ordinarily pursued, or the patient will fall a victim to the practitioner's systematic obstinacy.

Cold affusion, or ablution also of the skin, will be found as above intimated to favor the fulfilment of the second indication, of moderating excitement and heat, and conducing to a healthy and equable discharge from the surface of the body. The following regulations and restrictions respecting this practice we copy from the elegant volumes of the late Dr. Currie.

Whoever, says this author, has watched the progress of fever must have observed the justness of the observation made by Cullen, Vogel, De Haen and others, that even those genera which are denominated continued are not strictly such, but have pretty regular and distinct exacerbations and remissions in each diurnal period. In this space of time Dr. Cullen contends that an attentive observer may commonly distinguish two separate paroxysms. My observations do not enable me to confirm his position in its full extent, but one exacerbation and one remission in the twenty-four hours seem generally observable. The exacerbation usually occurs in the afternoon or evening, the remission towards morning. These exacerbations are marked by increased flushing, thirst, and restlessness. If the heat of the patient be at such times taken by the thermometer, it will be found to have risen one or two degrees in the central parts of the body above the average heat of fever, and still more in the extremities. The safest and most advantageous time for using the aspersion or affusion of cold water is when the exacerbation is at its height, or immediately after its declination is begun; and this has led me almost always to direct it to be employed from six to nine in the evening; but it may be safely used at any time of the day, when there is no sense of chilness present, when the heat of the surface is steadily above what is natural, and when there is no general or profuse sensible perspiration. These particulars are of the utmost importance.

1. If the affusion of cold water on the surface of the body be used during the cold stage of the paroxysm of fever, the respiration is nearly suspended; the pulse becomes fluttering, feeble, and of incalculable frequency; the surface and extremities become doubly cold and shrivelled; and the patient seems to struggle with the pangs of instant dissolution.

2. Neither ought it to be used when the heat measured by the thermometer is less than, or even only equal to, the natural heat, though the patient should feel no degree of chilness. This is sometimes the case towards the last stages of fever, when the powers of life are too weak to sustain so powerful a stimulus.

3. It is necessary to abstain from the use of this remedy when the body is under profuse sensible perspiration; and this caution is more important in proportion to the continuance of this perspiration. In the commencement of sweating, especially if it has been brought on by violent exercise, the affusion of cold water on the naked body, or even immersion in the cold bath, may be hazarded with little risk, and sometimes may be resorted to with great benefit. After sweating has continued some time and flowed freely, especially if the body has remained at rest, either the affusion or immersion is attended with danger, even though the heat of the body at the moment of using it be greater than natural. Sweating is always a cooling process in itself, but in bed it is often prolonged by artificial means, and the body is prevented from cooling under it to the natural degree, by the load of bed clothes. When the heat has been thus artificially kept up, a practitioner, judging by the information of his thermometer only, may be led into error. In this situation, however, the heat sinks rapidly on the exposure of the surface of the body even to the external air, and the application of cold water either by affusion or immersion is accompanied by a loss of heat and a deficiency of re-action, which are altogether inconsistent with safety.

Under these restrictions, says Dr. C., the cold affusion may be used at any period of fever; but its effects will be more salutary in proportion as it is used more early. When employed in the advanced stages of fever, where the heat is reduced and debility great, some cordial should be given immediately after it, and the best is warm wine. The general effect of the cold affusion, says Dr. Currie, in continuance will be more clearly illustrated by the following cases. They are a selection from a great number, the records of which have been preserved, and which lead to the same results. They are so arranged as to exhibit the salutary effects of this remedy in the different stages of fever, and illustrate the precautions laid down against using it improperly.

The first cases which Dr. Currie selects are those in which the affusion produced, according to his account, a complete solution of the fever; but in these cases the remedy was had recourse to before the fourth day; after that day, indeed for the most part after the third, the affusion does not, according to our author, usually produce an immediate solution of the disease, but it instantly abates it, and by a few repetitions brings it to a happy termination in two or three days.

As these cases of the late trial of the affusion are more appropriate to the present division of our subject we shall select one or two of the most striking of them, and leave the reader to make his own application.

A young lady of nineteen, in the seventh or eighth day of a typhus became my patient, September 26th, 1794. Her pulse was 112 and feeble, heat 101°. She had great pain in the head and much prostration of strength; her eyes were suffused and dull; her tongue furred; her spirits greatly depressed. Saline medicines were used for this patient, with lemonade for her usual drink, and moderate quantities of wine were given mixed with water. The burning sensation, in the palms of her hands and temples, was assuaged by frequent sponging with vinegar, and every evening at six P. M. three or four gallons of cold brine were thrown over her. The happy effects so frequently described were in this case particularly striking. The pulse fell almost immediately to 90, the heat to its natural standard, and the head ache vanished; a gentle diaphoresis followed with easy sleep; in a few hours, however, the feverish symptoms returned, and towards the hour of six in the evening the fever was in its highest state of exacerbation. At this hour, therefore, the affusion was repeated with the same happy effects; though the fever returned as before it was in a milder form; the same practice was continued, and on the 2nd of October she was entirely free from the disease.

The following is a case in which the cold affusion was employed in the more advanced periods of fever. It is related, we are told, circumstantially, because it contains the particulars of the narrator's practice in the epidemic, in which it occurred. In such instances, says our author, as might be expected, it does not procure the same advantages as in the earlier stages, when the strength is less impaired, and the morbid actions less firmly associated; nevertheless it is evidently advantageous, while the heat of the patient exceeds the natural standard, though it ought to be employed with caution in the more advanced stages of the disease, and in such cases, according to my later experience, of a temperature from 15° to 20° degrees only, below the human heat. In the greater part of the cases which Dr. C. recites the water employed was the pump water of the hospital, saturated with sea salt, and of a temperature from 40° to 50° of Fahrenheit.

F. G. a soldier of the thirtieth regiment, aged thirty-three, fell under my care on the 9th of June, 1792, during the prevalence of the epidemic in the regiment. He was in the ninth day of the disease. His pulse 100 and feeble; his heat 104°: his thirst was very great; his tongue foul and black; frequent cough occurred, with streaks of blood in the expectoration; and petichiæ appeared all over his body. His mind was at all times confused, and at times he was completely delirious. I directed that his strength should be supported by administering a bottle of wine every day with an equal quantity of gruel; that every night he should take an opiate draught; and that a complete operation of his bowels should be procured by a clyster administered daily, and, if this did not succeed, by a few grains of calomel. I also directed that a bucket full of salt water should be thrown over him immediately and repeated according to circumstances. In a few minutes after the affusion, the heat was 98°, the pulse 98, and his mind more calm and collected; two hours afterwards he had relapsed into nearly his former state, but the night was passed more tranquilly. The whole of this practice was continued with nearly the same result till the twelfth day of the disease, the affusion having always been performed in the evening, and sometimes at noon also. The fever continued its usual period; but on the twelfth day, the heat having sunk to its natural standard, the cold affusion was thenceforth omitted: we, however, sponged the whole body once or twice a day with vinegar. The patient was in a state of convalescence on the eighteenth day from the first attack.

Partly upon the same principles which regulated the above practice of employing cold water to the surface with a view to the abating of irritation, it is the practice of many, especially at the time in which we are now writing, to institute small and repeated bleedings, and in some cases this practice will be found very beneficial; it has lately obtained, partly on account of the prevalent notion of fever being necessarily connected with local inflammation; and although the doctrine may not be altogether stable, for fever seems capable of a full development and establishment without the presence of topical disorder, there is, it must be admitted, a tendency to such local manifestation in most distempers of the febrile class; and the plan of depleting in a moderate way, keeps as it were this tendency under, and may be considered as rather adding to, than subtracting from, the general energies of the system by equalising the circulating impetus. From four to six ounces may be taken according to circumstances, and at any time almost during the course of the fever, excepting when the tendency to sinking is marked and extreme.

Purgatives are almost invariably called for in all kinds and in most stages of fever. To keep the alimentary and intestinal canal free is one of the most important principles in conducting fevers to a favorable termination. When visceral obstructions are present, mercurial preparations may precede and alternate with saline and other purgatives; but the continued fevers which are met with in this country do not for the most part require very large and repeated doses of calomel.

Diaphoretics, especially those of the saline and cooling kind, are valuable medicines in fever; and it may be questioned whether anti-

mony which was at one time in more than due estimation is not now too little appreciated; like the cold affusion and ablution, and like small and judicious bleedings, antimony properly managed may be made to keep up a constant and regular action upon the excretories of the surface, and thus moderate re-acting violence, and assist in equalising the circulation.

Diuretics, likewise, of the saline and cooling order are occasionally administered in fever with much advantage. We do not now talk of concoction in the urine, nor do we direct our remedial measures towards effecting changes in the quality of this excretion; but it is of practical importance to recollect that conspicuous changes in the urine invariably attend changes in the disorder's aspect and character.

Refrigerants are obviously called for when heat is above the natural standard; indeed cold affusion and diaphoretics may by other terms be named refrigerants; however, the modus agendi of internal refrigerants is often attended with some difficulty in the explanation. That a little nitre dissolved in water should speedily bring down the heat of the whole body, some degrees, is not very easy to account for: the fact however would of itself be sufficient to show, that, as intimated in the preliminary discourse, much remains to be learned on the subject both of natural and morbid temperature, before pathology can congratulate itself on much accuracy of knowledge or precision of notion in reference to these particulars.

Formulæ for purgatives, diaphoretics, diuretics, and refrigerants, taken from Dr. Gregory and Dr. Uwins.

Purgatives.

℞ Pulveris jalapæ grana viginti.
Hydrarg. submuriatis grana quatuor.
Misce: fiat pulvis.

Take of powdered jalap a scruple, of calomel four grains. Make them into a powder.

℞ Magnesiæ sulphatis ʒvj.
Liquoris ammoniæ acetatis f. ℥ß
Syrupi simplicis f. ʒij.
Aquæ puræ f. ʒx.
Fiat haustus.

Take of Epsom salts six drachms, liquor of acetate of ammonia a fluid half ounce, simple syrup two fluid drachms, water ten fluid drachms. Make them into a draught.

℞ Potassæ tartratis ʒiß.
Syrupi aurantiorum f. ʒij.
Infusi sennæ f. ℥iß.
Fiat haustus.

Take of tartrate of potass one drachm and a half, syrup of orange peel two fluid drachms, infusion of senna a fluid ounce and a half. Make them into a draught.

℞ Pulveris jalapæ grs. xv.
Sodæ sulphatis ʒiij.
Fiat pulvis.

Take of powder of jalap fifteen grains, sulphur of soda three drachms. Make them into a powder.

Diaphoretics.

℞ Antimonii tartarizati gr. j.
Syrupi papaveris f. ℥iß.
Aquæ puræ f. ℥iiß.
Fiat mixtura. Dosis pars quarta.

Take of tartarised antimony one grain, syrup of white poppy a fluid ounce and a half, water two fluid ounces and a half. Make them into a mixture. Dose a fourth part.

℞ Liquoris ammoniæ acetatis f. ʒiij.
Vini antimonii tartarizati f. ʒj.
Syrupi papaveris f. ʒij.
Aquæ puræ f. ʒx.
Fiat haustus.

Take of liquor of acetated ammonia three fluid drachms, wine of tartarised antimony one fluid drachm, syrup of white poppies two fluid drachms, water ten fluid drachms. Make them into a draught.

Diuretics.

℞ Potassæ nitratis grana quinque.
Aquæ menthæ pulegii drachmas quatuor
Liquor. antim. tartariz. guttas quinque.
Tincti. digitalis guttas quinque.
Syrupi drachmam.
Misce: fiat haustus.

Take of nitre five grains, four fluid drachms of pennyroyal water, liquor of tartarised antimony five drops, tincture of digitalis five drops, syrup a fluid drachm. Mix into a draught.

℞ Potassæ nitratis ℈ß.
Spiritus ætheris nitrici f. ʒj.
Misturæ camphoræ f. ℥iß.
Syrupi simplicis f. ʒj.
Fiat haustus.

Take of nitre half a scruple, spirit of nitric ether a fluid drachm, camphor mixture a fluid ounce and a half, simple syrup a fluid drachm. Mix for a draught.

℞ Potassæ acetatis ʒj.
Syrupi simplicis f. ʒij.
Aquæ puræ f. ℥iß.
Fiat haustus.

Take of acetate of potass a drachm, simple syrup two fluid drachms, water a fluid ounce and a half. Make them into a draught.

Refrigerants.

℞ Potassæ nitratis ℈ß.
Syrupi simplicis f. ʒij.
Aquæ puræ f. ℥iß.
Fiat haustus.

Take of nitre half a scruple, simple syrup two fluid drachms, water ten fluid drachms. Make them into a draught.

℞ Potassæ supertartratis ʒvj.
Sacchari purificati ℥iv.
Corticis aurantiorum ℥ß.
Aquæ ferventis o.iij.
Misceantur pro potu.

Take of cream of tartar six drachms, purified sugar four ounces, orange peel half an ounce, hot water three pints (imperial). Mix for a drink. For the mode of making the saline

draught to be drunk in a state of effervescence, see under the head of intermittent fever.

Indication 3. When obviously marked debility prevails, stimulants and cordials appear to be called for. It will be found, however, that these artificial excitants are much less admissible in febrile weakness and sinking than would, à priori, be imagined. Some systematists have gone so far as to forbid altogether the employment of stimuli in fever, while others have pushed them through thick and thin without regard to any other considerations than the prevailing lowness of the vital energies. Both extremes are wrong.

The propriety of stimuli seems questionable, while any of the secretions or excretions are in a manner locked up; especially when the bowels are constipated, the stomach laden, and the surface of the body in a dry unperspirable state; when the pulse too is sharp, as it is expressed, that is wanting in softness and fulness, then we must be careful how we meet the weakness with exciting agents. But when the patient lies prostrate under the pressure of typhoid lowness, the bowels being loose, the skin open, and the tongue disposed to moisture, we should be losing ground by withholding supporting powers. Under these circumstances, too, opium will meet and subdue the restlessness of fever, without being attended by any injurious consequences. Dr. Currie's rule, in respect to the time and circumstances of opium's admission, will be found of importance to recollect; it may be given, he says, when the stomach is empty of food, the bowels loose, and the skin moist; and, as above intimated, these are conditions generally for the admission of the excitantia in fever; one of the most beneficial and least objectionable of which is the subcarbonate of ammonia.

℞ Ammoniæ subcarbonatis ℈ß.
Confectionis aromaticæ ℈j.
Aquæ puræ f. ℥iß.
Fiat haustus.

Take of sub-carbonate of ammonia half a scruple, aromatic confection one scruple, water a fluid ounce and a half. Make them into a draught.

℞ Liquoris ammoniæ acetatis f. ʒiij.
Ammoniæ subcarbonatis gr. vi.
Misturæ camphoræ f. ℥iß.
Fiat haustus.

Take of liquor of acetate of ammonia three fluid drachms, sub-carbonate of ammonia six grains, camphorated mixture a fluid ounce and a half. Make them into a draught.

℞ Tincturæ opii m. xv.
Succi lemonum f. ℥ß.
Aquæ puræ f. ℥iß.
Fiat haustus.

Take of tincture of opium fifteen minims, lemon juice half a fluid ounce, water a fluid ounce and a half. Make a draught.

The black drop may often be employed with advantage where opium is required, but seems of doubtful admissibility. One drop of this last is equal to four or five of the tinctura opii. The liquor opii sedativus of Battley is also useful in being without some of the deleterious qualities of the common tincture. The dose of Battley's liquor is from fifteen to thirty drops.

When what are called putrescent symptoms make their appearance, the mineral acids will be found occasionally of abundant service; some practitioners trust almost entirely to the use of these in those kinds of fevers which tend towards the typhus gravior of authors.

℞ Acidi muriatici,
Acidi nitrici ā ā. m. ij.
Syrupi simplicis f. ℥ß.
Aquæ puræ ℥iß.
Fiat haustus.

Take of muriatic acid and nitric acid of each two minims, simple syrup half a fluid ounce, water a fluid ounce and a half. Make them into a draught.

℞ Acidi nitrici diluti f. ʒij.
Syrupi aurantiorum f. ℥ij.
Aquæ puræ f. ℥x.
Misce pro potu communi.

Take of diluted nitric acid two fluid drachms, syrup of orange peel two fluid ounces, water ten fluid ounces. Mix them for a common drink.

℞ Acidi sulphurici diluti m. xij.
Decocti cinchonæ f. ℥iß.
Syrupi papaveris, f. ʒij.
Fiat haustus.

Take of diluted sulphuric acid twelve minims, decoction of bark a fluid ounce and a half, syrup of white poppy two fluid drachms. Make a draught.

Cascarilla, valerian, serpentaria, camphora, and the æthers are in use, when the fever exhibits the typhus mitior or nervous, rather than the typhus gravior, or, as it would be said by some, putrid aspect. It is necessary to observe that, when camphor is administered with any other intention than that of a mere adjunct to other medicines, the dose ought to be much larger than can be given in the mixtura camphoræ of the pharmacopœia. It should be exhibited in doses from six to ten grains, either rubbed down with mucilage of acacia, or in the form of bolus. Hyoscyamus is a useful medicine in nervous fever, when sleep is required, and opium is forbidden.

℞ Tincturæ hyoscyami, f. ʒß.
Camphoræ, gr. vi.
Mucilag. acaciæ, f. ʒi.
Spiritus ætheris nitrici, f. ʒi.
Syrupi simplicis ʒi.
Aquæ puræ, f. ℥i.
Fiat haustus.

Take of tincture of henbane half a fluid drachm, camphor six grains, acacia mucilage a fluid drachm, spirit of nitric ether a fluid drachm, simple syrup a fluid drachm, water a fluid ounce. Make them into a draught.

In colliquative diarrhœa, the opiate confection will be found an efficacious medicine.

℞ Confectionis opii grs. xv.
Aquæ cinnamomi f. ℥iß.
Fiat haustus.

Take of opiate confection fifteen grains, cinna-

mon water a fluid ounce and a half. Make a draught.

But the young practitioner must always be careful not to interfere too much with nature's operations by precipitately checking an evacuation, which, if it takes place while the powers of the system are yet vigorous, and is not exhaustingly profuse, may be looked upon as salutary rather than injurious, and ought to be assisted by slight and mild mercurials; as with five grains of the pilula hydrargyri, or one grain of calomel, rather than immediately suppressed by opium and astringents.

Should hæmorrhage take place from the bowels, a considerable dose of tincture of opium, from thirty to forty minims, may be resorted to with much promise of advantage, and the Peruvian bark with sulphuric acid, and syrup of white poppy be afterwards employed according to the extent of sinking manifestation; but, even in these cases, we must be on our guard against too much of astringent agency.

Of the external applications that are made use of occasionally in the management of fever very little need be said. In cases of much cerebral disturbance, leeches are often demanded for the temples; and it occasionally becomes expedient to have the head shaved, and to keep the naked scalp constantly wetted with an evaporating lotion.

℞ Liquoris ammoniæ acetatis f. ℥vij.
Spiritus ætheris sulphurici f. ℥j.
Fiat lotio.

Take of liquor of acetated ammonia seven fluid ounces, spirit of sulphuric ether one fluid ounce. Make a lotion.

℞ Ammoniæ muriatis ʒiß.
Aquæ puræ f. ℥viß.
Spiritus rectificati f. ℥iß.
Fiat lotio.

Take of muriate of ammonia (sal ammoniac) a drachm and a half, water six fluid ounces and a half, rectified spirit a fluid ounce and a half. Mix them for a lotion.

Some practitioners are accustomed to apply blisters to the scalp in the event of cerebral affection proving urgent. This appears to be a questionable practice. Blisters ought rather to be applied to the nucha, or legs, and not to the head; and where the vascular irritation is so high as to call for either topical or general blood letting, this ought always to be premised, and the blisters not had recourse to till after the vessels have been emptied.

Whether convalescence from fever should be treated by tonics, especially by Peruvian bark, has been made a question in modern times; indeed, it is the more common custom in the present day to leave the confirmation of health and strength entirely to time and nature. We find, however, that relapses from fever are by no means infrequent; and it may be that the departure from the 'throwing in bark' practice has been too freely and fearlessly carried to the extent of throwing it entirely aside. It is probable, at least, that a little tonic operation upon the nervous and vascular organisation of an individual recovering from a protracted disorder may obviate the tendency to the recurrence of those actions by which the disorder was constituted. The sulphate of quinine seems well adapted to the circumstance of convalescence, as it is powerful without being bulky and nauseating.'

Recapitulation of the treatment in continued fever.

1. To endeavour to cut it short, either by the administration of an emetic, of a violent or drastic purgative, or by blood-letting to a pretty considerable amount, or by dashing cold water over the naked body.

2. To endeavour at conducting it to a safe termination, or assist in expediting such termination by moderate blood-lettings at any time of the fever's course that heat and irritation seem to demand it, to wash or sponge the body with cold water during the existence of dry heat, or to dash cold water over the body in the way of affusion, to administer saline purgatives, or diaphoretics, or diuretics, or refrigerants; and in cases of decidedly marked topical affection to apply leeches or cold evaporating lotions over the parts affected; and when there are indications of visceral disorder, especially of the liver, to give calomel or blue pill in combination with the purgative medicines.

3. To support the powers of life when they appear sinking under the violence of the commotion, by ammonia, wine and cordials, always recollecting that these kinds of stimuli are then most admissible when the skin is in an open state, and the pulse free from constricted sharpness; to administer opium and wine when diarrhœa or hæmorrhage from the bowels are urgent, still acting under the impression that care must be taken not to check precipitately those discharges which seem manifestations of nature's efforts to procure a solution of the disease; to administer those vegetable tonics which are more especially adapted to nervous weakness, when the malady seems as it were to fix upon the nerves, rather than tend to typhus gravior; these tonics are valerian, serpentaria, &c.; to allay irritation by vegetable narcotics, such as henbane, when opium is inadmissible; and lastly to assist convalescence by the moderate use of bark in one or other of its forms.

343. *Means of prevention?*—Before concluding the subject of general fevers, it will be expected that we introduce a few remarks on the means of prevention: of which, by the way, much more has been said than the facts of the case have warranted; separation and free ventilation being after all the most efficacious means of obviating the communication of the malady. It should seem that the poison of whatever nature and kind it may be, is received into the system through the medium of the lungs; for while the skin is whole or unabraded, that is while the cuticle or scarf skin properly covers the cutis vera or true skin, the poison of contagion cannot make its way into the system. Merely lay the most virulent miasm upon the outer skin of an individual, say the small pox virus, or even the virus which produces hydrophobia, and no harm will be done. For the body to be infected, it is necessary that a puncture or abrasion be made of this outer surface, so as that the matter infecting shall

get to the blood vessels, or nerves, or absorbents. Experiments, moreover, have been made, which are at variance with the notion that might be entertained of the stomach being an inlet to these infecting materials, or that the individual swallows the poisons which produce their specific effects. Dr. Rush, of Philadelphia, caused a negro girl to swallow some small-pox matter, and it was done without producing the disease; so that in point of fact all that is to be feared, or at any rate the most that is to be apprehended, is taking into the lungs by inspiration the matter immediately emitted from the lungs of another; or the matter exuded by the sick, whether immediately exhaling from his body or having been collected and concentrated in some material with which his body has been in contact. These simple facts being admitted, it necessarily follows that, as above stated, plenty of washing so as to prevent the collection and concentration of the materies morbi, and a plentiful supply of fresh air, so as to prevent as much as possible a poisonous atmosphere, are the main particulars of preventive measures. It is questionable whether the aromatics and perfumes that have been had recourse to under the notion of disinfection or preservation may not be sometimes worse than useless, excepting as they may bring with them a confidence of their efficacy; for a careless and confident state of mind with regard to infection would seem occasionally some sort of guarantee against its influence.

We may not, perhaps, assume that this is the explanation of the comparative immunity of medical attendants and nurses, more especially of the latter; for these seem to be guarded in some measure by a law which obtains in reference to a contagious atmosphere, viz. that those who are constantly inhaling it are much less obnoxious to its poisonous influence than those who are only partially and occasionally exposed.

'As a matter of prevention,' says Dr. Thomas, in his very comprehensive and useful work entitled The Modern Practice of Physic, 'strict non-intercourse with the sick should be enforced, and those whose duty or kindness leads them to visit the patient, should be very careful not to inhale his breath, or expose themselves to that steam of perspirable matter which emanates from his body when the bed clothes are turned down for the purpose of rendering him any offices of assistance. While engaged in such duties they should retain their breath for a time; and, if under the unavoidable necessity of inhaling the tainted atmosphere, they should, as soon afterwards as possible, blow from the nose, spit, or wash their mouth, with a view of detaching any infectious particles that may have adhered to these passages. All the discharges of the patient should be thrown away to some distance as soon as they are rendered, and the vessel washed with boiling water. But the most important precaution of all is to maintain a perpetual circulation of air in the patient's chamber throughout the whole course of the disease; and for this purpose a part of the window should be left open both at top and bottom, and the opposite window where there is one, or else the door of the room, should also be a little opened. For the better success of ventilation the bed curtains should never be drawn close round the patient but merely one of them let down to screen him from the irritation of light. When open windows cannot be had recourse to on account of high winds, or other inclemency of the weather, a small fire must be kindled in the grate, so as to cause a current and frequent removal of air in the chamber without considerably raising the temperature. Another essential precaution consists in frequently changing the body and bed linen of the patient, which, as soon as removed and carried away, may be put into a tub and covered over with water, into which a handful of lime or potash may be thrown, for the purpose of detaching the animal matters with which they may be impregnated. In few words,' he adds, 'unremitting regard to ventilation, and the strictest attention to cleanliness in all its parts, constitute the whole secret of evading contagion. Fumigations with nitric or muriatic acid in a state of vapor may however be employed as auxiliaries.'

We shall extract the brief history and account that this minute and practical author, Dr. Thomas, gives of the practice of fumigation as a preventive and counteractive of febrile contagion.

Nitric acid has been used by Dr. Carmichael Smyth as a fumigation, with the greatest success, in malignant fever. In the year 1780 the disease broke out among the Spanish prisoners confined in Winchester Castle: he embraced the opportunity of giving the remedy a fair trial, and obtained the most decisive evidence of its happy power in preventing the spreading or farther communication of the infection. He found he could use it without risk or inconvenience to respiration, and therefore thought it the most proper antidote to be applied where persons are unavoidably obliged to be present.

The doctor's mode of obtaining nitric acid is by decomposing nitre by means of heated sulphuric acid, which may be done as follows: Put half an ounce of this acid into a crucible, glass, china cup, or saucer, and warm this over a lamp, or in heated sand, adding to it from time to time some nitre; these vessels he directs to be placed at twenty or thirty feet distance from each other, according to the height of the ceiling, and virulence of the contagion. In hospitals and prisons he advises the lamps, or vessels containing heated sand, to be placed on the floor; but on board of ships he recommends to hang them to the beams by waxed silk cords.

From the well known efficacy of the sulphuric acid, in destroying contagion, he advises it to be employed as a fumigation for clothes and furniture, &c.: but for purifying empty prisons, hospitals, wards, and ships, he gives the preference to the nitric, its vapors being more volatile and penetrating, and not having the disagreeable smell which the sulphuric has, and thinking it at the same time equally efficacious.

Monsieur Guyton Morveau, in his treatise on The Means of Purifying Infected Air, claims the merit of being the discoverer of the power of the mineral acids to destroy contagion, and endeavours to establish the superiority of the muriatic acid over all others. Upon a full investigation of the matter it appears, however, that the power

of the mineral acids to destroy contagion was know to Sir John Pringle as early as the year 1750; and their utility for that purpose was mentioned by Dr. Johnson in his pamphlet published in 1758, in which we are told that the vapor of muriatic acid was successfully employed by him in correcting the contagion of a very malignant fever, which had raged at Kidderminster two years before that period.

Dr. Smyth has also claimed the having been the first who used the mineral acid gas in the apartments of the sick, and has alleged that they never had been employed by Dr. Johnson but in places where no one was present, or where the sick were removed. This opinion has been refuted by Dr. Johnson's son, and the invention of his father most incontestably established. What Dr. Smyth seems therefore entitled to is the merit of having brought the discovery into public notice, and of having applied and extended it to general use.

It seems of little consequence whether we employ the nitric acid or the muriatic, in the form of gas for the purpose of destroying contagion, and purifying infected air, as the powers of both are extensive and certain. The muriatic is, however, thought to be more diffusible than the other. When we give it the preference it may be used in the following manner:—Put one pound of common salt into an earthen vessel, and pour over it from time to time a small quantity of sulphuric acid, till the whole salt is moistened. If the air is foul, and peculiarly offensive, apply a gentle heat under the vessel to extract a large quantity of vapor: but in general the simple addition of the acid to the salt will be found sufficient, unless the apartment is very large.

The most effectual, however, of all fumigations is perhaps the following; but it requires some nicety:—Take of manganese, in powder, two parts, the same of common salt, of sulphuric acid three parts, and of water one part. Put an ounce of the mixed manganese and salt into a basin; add of water a large tea spoonful, then drop in half a tea spoonful of sulphuric acid, and repeat this till you have used a tea spoonful and a half of the acid. In this manner keep up a sensible extrication of the fumes.

On the appearance of typhus, or any infectious disorder, in a gaol, hospital, workhouse, garrison, transport ship, or any other place where many persons are crowded together, we should not fail to advise one of these gaseous fumigations in every room, in addition to a free ventilation and the greatest cleanliness. The same steps should be adopted in academies, boarding-schools, and even our dwelling-houses.

The principal objections against these acid fumigations are, that they occasionally oppress the breathing of individuals whose respiratory functions are already perhaps morbidly affected, and that they tarnish the furniture of the rooms, at least the metallic part of such furniture. More recently still the chloruret of oxide of sodium, and the chloruret of the oxide of calcium, have been substituted for the fumigation above alluded to. Waters, impregnated with these chlorurets, are aspersed about the apartments, and are alleged to possess to the full the disinfecting tendency of the acid fumigations, without any of their inconveniencies. M. Labarraque of Paris was the first to propose the employment of these substances as disinfecting materials; and Mr. Alocock has lately published an interesting pamphlet on their application, not only to the purposes now particularly referred to, but under several other circumstances of disease. To the article PHARMACY the reader is referred for an account of the preparation of these substances, and they are now prepared by Mr. Beaufort, for disinfecting animal food as well as for preventing the spread of contagious disease.

Typhus icterodes, yellow fever. The student, by referring to the nosology, will find that Cullen places this as a species under the genus typhus; and on this account it falls here to be considered. The remarks which we have already introduced under the general head of fever, and the disquisition in which we have already engaged, both in the preliminary part of the present article and when considering the existing causes of fever generally, might seem to supersede the necessity of any lengthened account of the symptoms, sources, and treatment, of the malady now to be noticed; but it demands somewhat of particular consideration, inasmuch as it has occupied the pens of controversial writers for years, and its precise nature and habits are still the subject of dispute.

It is still, we say, a disputed point, whether there is any disease, of a specific and peculiar kind, to which the term yellow fever may legitimately apply, or whether all its forms are not merely modifications of endemic fever, or of a fever which owes its peculiarities not to the specific and abstract nature of its exciting causes, but to the local circumstances of soil, temperature, air, &c., of the places in which it breaks out and spreads. It would seem to us probable that this discussion has been agitated too much in the abstract, or under the supposition that the disorder must be absolutely one or the other:—either common, that is, excited by the ordinary excitants of fever; or specific, that is, equally independent of time, place, and circumstance, as is small pox, or measles. To our conception, we repeat, both yellow fever, and a form of disease afterwards to be commented on, the plague, seem to hold a sort of midway condition in respect of peculiarity or specific character; and that while both are communicable by means of a particular poison, and both susceptible of transportation from one country to another, the clime in either case, to which the virus is transported, must be naturally or artificially such as to assist in the consequent development and spread of the disease. Who, it has been asked, ever heard of the yellow fever in the north of Europe? but small pox we all know is a distemper which has appeared in the south and in the north, in the east and in the west.

In the present case, however, it behoves us to recollect that we are encyclopædiasts rather than essayists, and that it is our duty rather to concentrate the opinions of others than to prefer our own. Under this impression we deem it proper to present a general account and estimate of the

yellow fever from the writings of others, and, in this instance, we shall bring into requisition the very able author of the Study of Medicine, who, after treating of remittent fever generally in its various shapes and modifications, goes on to say, 'One of the severest and most fatal forms under which the malignant remittent shows itself is that of the yellow fever, so denominated from the lemon or orange hue which is thrown over the entire surface of the body almost from the first attack of the disease, and which gives it a distinctive feature. The heat is here also intense, the thirst extreme, and the vomiting strikingly obstinate; but not consisting of a colorless material, or the food which has been swallowed, but of a yellowish matter at the beginning and through the height of the fever, and of a chocolate colored colluvies towards its close.

'The common remote cause of this fever is unquestionably marsh miasm; and hence it holds a stationary abode in the swampy soils and morasses of the inter-tropical regions, exposed to a high solar heat, and perpetually exhaling a decomposition of animal and vegetable materials; and is found occasionally in all climates that make an approach to the same characteristic; where, in the language of the poet,

The rivers die into offensive pools,
And, charged with putrid verdure, breathe a gross
And mortal nuisance into all the air.

And, as almost every territory in which it has committed its ravages has given it a new name, it is as gorgeously arrayed with titles as the mightiest monarch of the east. From the depredations it has committed in the West Indies and on the American coast it has been called the St. Domingo, Barbadoes, Jamaica, and American fever: and from its fatal visitation on the Guinea coast, and its adjoining islands, the Bulam fever. In British India it is distinguished by the name of the jungle fever, and still further to the east by that of Mal de Siam. Nearer home, in the lowlands of Hungary and along the south of Spain, it is called the Hungarian or the Andalusian pestilence. From its rapid attacks on ships' crews that are fresh to its influence the French denominate it fievre matillote, as the Spanish and Portuguese call it vomito prieto, or black vomit, from the slaty or purplish and granular saburra thrown up from the stomach in the last stage of the disease, while, as its ordinary source is marsh lands, it has frequently been named paludal fever. Its more common name, however, in the present day, and for the reason already assigned, is yellow fever; and, when the attack upon new comers is slight, seasoning.

From its showing itself in so many parts of the world, and under circumstances so widely different, it is not to be wondered at that it should often be accompanied with a considerable diversity of symptoms, and consequently that the paludal fever of one quarter should be regarded by many writers of considerable authority as essentially different from that of another. But an attentive perusal of the origin and laws of febrile miasm, as I have endeavoured to explain them when treating of the remote causes of fever, will, I trust, be sufficient to account for all such local distinctions, and if not to prove, at least to render it highly probable, that they depend partly upon the state of the body at the time of the attack, but chiefly upon some modification in the powers or qualities of the febrile miasm itself, by the varying proportions of the co-operative agents of moisture, heat, stagnant air, and other auxiliaries which have not yet been detected, in their relation to each other in different places and seasons.

How far the yellow fever is capable of origination from any other cause than febrile miasm from marshy lands, we cannot at present determine. When, however, it has once firmly established itself and raged with severity, it is now very generally admitted that the effluvium from the body of the affected is loaded with miasm of the same kind, completely elaborated as it passes off; and that the disorder is from this time capable of communicating itself by contagion. And it appears far more probable that the fever at Cadiz in 1800, and that at Malaga in 1803, had their origin in contagion, or, in other words, in febrile miasm, produced by a decomposition of the effluvium from the human body, than from the same miasm issuing from a decomposition of marsh lands. And on this account I have rather preferred the trivial name of yellow to that of paludal fever, which is too limited to express its source in every instance.

From the different impressions produced on febrile miasm, under these diversities of origin and adjuncts, we find, independently of other discrepancies, that the fever it excites sometimes assumes a caumatic or inflammatory cast, sometimes a typhus, and sometimes a synochus, or, in other words, begins with the first and runs rapidly into the second or third. Generally speaking, the variety before us evinces the last of these characters, as does also the variety we have just treated of: the two varieties that yet remain will afford examples of a typhous and inflammatory bearing.

Its ordinary progress amongst those who are fresh to the tainted atmosphere is thus accurately described by Dr. Moseley, who, from its resemblance to the causus of Hippocrates, denominates it endemial causus. 'When a new comer is seized with a sudden loss of strength, and a desire of changing for rest, into every position without finding it in any, those symptoms which constitute the endemial causus may be expected. The following day, but sometimes within twelve hours from the first indisposition, the violence of the disease will commence thus: there will be a faintness and generally a giddiness of the head, with a small degree of chilness and horror, but never a rigor. Then immediately will succeed a high degree of fever, with great heat and strong beating in all the arteries of the body, particularly observable in the carotid and temporal arteries; flushings in the face; gaspings for cool air; white tongue, but tinged with yellow, after the retchings have commenced; excessive thirst, redness, heaviness and burning in the eyes; heaviness and darting pains in the head and small of the back, and often down the thighs; pulse quick, generally full and strong; in some cases

quick, low, and vacillating; skin hot and dry; sometimes with a partial and momentary moisture; sickness of the stomach from the first, which increases with the disease; and, immediately after any thing is taken to quench the thirst; retchings succeed in which bilious matter is brought up; anxiety with stricture, soreness and intense heat about the præcordia; great restlessness; heavy respiration; sighing; urine deep colored and but little in quantity. This is the first stage of the fever, and may continue twenty-four, thirty-six, forty-eight, or sixty hours, and this constitutes its inflammatory period.

The second stage begins with an abatement of many of the preceding symptoms, and the rise of others, sometimes with a deceiving tranquillity, but with perturbation if the patient should fall into a sleep; then a yellow tinge is observed in the eyes, neck, and breast; the heat subsides and sometimes with a chilness, but not with that sort of strong rigor which, when it happens, terminates the disease by sweat, or by copious bilious evacuations upwards or downwards. The retchings are violent, and turn porraceous; the pulse flags, but is sometimes high, and sometimes soft; the skin soft and clammy; the urine in small quantity, and of a dark croceous color; the tongue in some cases is dry, harsh, and discolored; in others furred and moist; there is confusion in the head and sometimes delirium; with the eyes glassy. This stage of the disease sometimes continues only for a few hours, sometimes for twelve, twenty-four, thirty-six, or forty-eight hours, but never longer.

In the third and last stage of the fever the pulse sinks and becomes unequal and intermittent, sometimes very quick; frequent vomiting with great straining, and noise in vomiting, and what is brought up now is more in quantity, and has the appearance of the grounds of coffee, or is of a slate color. Nothing can be retained in the stomach; difficult breathing; tongue black; cold clammy sweats; eyes hollow and sunk; yellowness round the mouth and temples, and soon after over the whole body.

These symptoms become gradually more aggravated, accompanied with subsultus tendinum, black urine, deadly coldness of the limbs, delirium, faltering speech, hæmorrhage, or oozing of blood from the mouth and nostrils, corners of the eyes, and ears; black bloody vomiting and stools; vibices, hiccough, muttering, coma, death.

After the first prostration of strength the disease runs on violently till the sensorial power is exhausted. Through its entire course, till the patient is sinking, the intellect is not particularly disturbed, and the organs chiefly affected are the abdominal; those which principally suffer in the malignant autumnal remittent of our own country, more especially the stomach and the liver. Hence the intense heat and anxiety about the præcordia, the saffron dye of the urine, the yellow tint of the skin, and the vomitings, first of a bilious and afterwards of a chocolate or sanguineous colluvies.

In some cases the disease opens with great vehemence and rushes forward at once to its acmé, constituting the second stage of Dr. Moseley. The patient is sometimes cut off in four-and-twenty hours; and, from the violence so suddenly committed on the liver, its proper function is instantaneously suspended, and, instead of an excessive emulgence of high-tinted bile, a chlorotic secretion takes place, which, forced into the sanguineous system, gives a ghastly lividity to the entire surface. Shortly after which, if the patient live long enough, the gorged blood-vessels of the inflamed and gangrenous liver itself, and sometimes also of the spleen or stomach, give way, and repeated tides of dark granulated grume, like the grounds of chocolate, are ejected by the mouth.

Mr. Pym has very forcibly described this overwhelming onset of the disease in the following terms: 'There is at the first attack a peculiar, heavy, or drunken appearance in the eyes; the head-ache is excruciating, and, confined to the orbits and forehead, has no remission; when it terminates favorably it is rarely attended with yellowness of the skin, which, if it do take place, is of a very pale lemon color. It runs its course from one to five days; is attended with a peculiar inflammation of the stomach, which, in most cases that prove fatal, terminates in gangrene, or in a diseased state of the internal or villous coat of that organ, accompanied with a vomiting of matter resembling coffee grounds, and a livid or putrid appearance of the countenance which it is impossible to describe; but those wishing to form an idea of it may see its fac simile in the countenance of any person with a florid complexion, during the burning of spirits of wine and salt in a dark room, as is practised in the game of snap-dragon during the Christmas gambols.'

In this state the disease is unquestionably contagious; and as Dr. Cullen has laid down contagion as a distinctive character of fevers originating from human effluvium, in contrast with those originating from the effluvium of marshes, Mr. Pym has endeavoured to draw a line of distinction between yellow fever in this state of intensity and in its ordinary career; contending that the former (to which he limits the name of Bulam fever) is in every instance derived from human effluvium, and consequently that the two must of necessity be distinct diseases. And, to make the distinction still clearer, he has ventured to assert that the symptoms of a more pallid or bloated countenance, together with that of black vomit, or the discharge of coffee-like grounds from the stomach, is peculiar to the contagious fever, and is rarely, if ever, attendant on that produced by marsh miasm even in its most impetuous and fatal course.

This distinction, however, is in both instances at variance with the history of the disease as it has occurred in most other parts of the world, and more especially with respect to the symptom of black vomit, which in its last stage, or severer incursions, is common to it, from whatever source derived. It occurred more especially in the fatal epidemic of Antigua in 1816, which was decidedly an offspring of marsh effluvium. The island had for some years, observes Dr. Musgrave, at whose description we have already glanced slightly, been peculiarly healthy; and the disease first showed itself in a swampy part of it, and amidst new comers, who were sailors,

but from a healthy ship, and themselves in good health on first landing. It soon spread widely, and at length indiscriminately, among all ranks, and conditions, and situations; among blacks and whites, the newly arrived, and the oldest settlers in town and country.

Nothing was better calculated than this fever to show that almost all the different kinds of fever that occur to us are capable of issuing from a common source or miasm, merely modified by contingencies; for, in Antigua, they all occurred in different individuals. The disease sometimes commenced as an intermittent or remittent, and sometimes in a continued type; it sometimes ceased in four or five days, which was its usual course, and sometimes terminated in an intermittent. The head was in some cases chiefly affected; in others the stomach, liver, or some other organ. Sometimes the patient died without hiccough, or black vomit, though he rarely recovered where these symptoms appeared: Dr. Musgrave recollects but one instance. Recovery was no exemption against a second attack. In new comers the tint was of a lemon hue; in natives, or assimilated constitutions, of a deep orange. The state of the atmosphere, at the commencement of the disease, presented nothing peculiar.

In the midst of the discrepancy between these two accounts there is still much that is concurrent; and quite enough to establish the identity of the two diseases, if an abundance of other evidence to the same purpose were not at hand. The fever of Mr. Pym, specifically characterised by black vomit, is represented as being peculiarly dangerous and fatal; in that of Dr. Musgrave, this symptom only occurred in the most dangerous cases of the malady. According to the latter, the severest and most deadly attacks were amongst the new comers; the mildest amongst the natives, or those whose constitutions were assimilated to the climate. The yellow hue of the former was of a deep orange; that of the latter a lemon color. Mr. Pym describes three species of fever as common to warm climates, but which differ from each other in their mode of origin, and diagnostic character. In that of least danger the color of the surface, he tells us, is of very deep yellow; in that of higher danger it is of a deep yellow; and in the disease before us, which is by far the most fatal, where there is any yellow at all, it is of a very pale lemon color; which is, in effect, the very hue ascribed to the severest cases of the Antigua fever by Dr. Musgrave, as the very deep yellow or orange is to the mildest. So that, examined by their external livery, as well as their internal disorganisation, there can be no doubt that the two diseases are the same. Mr. Pym appeals peculiarly, as a distinctive character of the Bulam fever, to the deadly and chlorotic paleness exhibited by the countenance in its latest stage, or most fatal incursion. But even this only shows that, in such case, the disease makes a mortal attack upon the larger viscera, and especially the liver, from the first; and demonstrates the proposition I have ventured to lay down, that, in proportion as this organ is severely affected, is its inability to secrete proper bile, or indeed bile of any kind; and, consequently, that if the irritation only reach a certain point, the secernents will be stimulated to emulge a larger quantity, and of a deeper hue; a considerable portion of which, in consequence of such irritation extending to the neighbouring absorbents, will be sent back into the sanguiferous system, and produce the orange tinge, which, in the description of both these writers, peculiarly marks the disease before us in its less fatal attacks. While, if the febrile incursion be so violent as totally to derange the function, and still more the structure of the liver, no bile will be secreted at all, or, if secreted, less in quantity, and consequently less diffusive in color; and hence only conveying a chlorotic or livid tinge to the face, which, at the same time, exhibits a bloated fulness from effusion or debility of vascular action.

Yet, after all, it is not denied by Mr. Pym, nor, so far as I know, by any of the writers on the American or Andalusian fever, that the yellow fever from marsh miasm ever evinces either of the symptoms that are so essentially ascribed to the bilious remittent produced by contagion; but only that it is rarely, if ever, to adopt Mr. Pym's own words, attended with the fatal symptoms peculiar to the Bulam fever, viz. the black vomiting, and a peculiar bloated appearance of countenance.

There would, however, be an almost insurmountable difficulty in reconciling these different descriptions of the same disease, in consequence of Dr. Musgrave's telling us very decidedly that not a single instance occurred in the Antigua fever of its being received by contagion, were there not strong reason for believing that this explicit writer suffered himself to be deceived on this point; most probably, like Mr. Pym, from too close an attachment to the doctrine laid down by Dr. Cullen, that the fever from marsh miasm does not produce contagion, which is specifically a result of a fever from human effluvium.

It is impossible to peruse the history of bilious remittent in warm climates, offered from all quarters, without seeing that it may and does originate from both sources; each sometimes operating alone, and sometimes in conjunction with the other, as was probably the case at Antigua, and certainly the case in the yellow fever that raged at Philadelphia in 1793; in which, says Dr. Rush, there were for several weeks two sources of infection, namely, exhalation and contagion. The exhalation infected at the distance of 300 and 400 yards; while the contagion infected only across the streets. The more narrow the streets, the more certainly the contagion infected. Few escaped it in alleys. After the 12th of September. the atmosphere of every street in the city was loaded with contagion; and there were few citizens in apparent good health who did not exhibit some mark or other of it in their bodies, particularly a preternatural quickness in the pulse, which occurred in negroes as well as in whites; and in a few who had had the disease before.

That febrile miasm, produced from human effluvium is less volatile than that from marsh miasm, and consequently more limited in its range of infection, is consistent with common

observation. It is sufficient to observe, on the present occasion, that the disease thus issuing from two distinct sources, was one and the same in its general symptoms, and yielded to a like treatment, thus establishing satisfactorily what, indeed, Dr. Rush himself does not seem to have apprehended, that, though remotely issuing from two distinct sources, it was immediately excited by a common miasm thus doubly generated, and which was only modified in its action by the nature of its origin, or by contingent powers.

Unfortunately the practitioners in warm climates have differed as much in their therapeia as in their ætiology; and apparently the cause that has produced the one has produced or greatly influenced the other. Mr. Halliday, alarmed at the debility which the system will have to encounter in the second stage of the disease, or as soon as it has run through its inflammatory career, shuddered at the thought of the lancet, commenced with slight purgatives of sulphate of magnesia and manna, and immediately afterwards had recourse to the bark. The practice of Dr. Hillary was something less timid; for he allowed an abstraction of from twelve to twenty ounces of blood on the first, and even in a few cases again on the second day, according to the patient's strength and constitution. While Dr. Rush, on the other hand, regarding the inflammatory impetus as the sole cause of danger, boldly resolved to lay prostrate if possible the morbid Hercules at its birth, by bleeding according to the state of the pulse, two or three times a day during the first two days, and by following up the same plan as long as a single germ of inflammatory diathesis should continue manifest. 'I paid no regard,' says he, 'to the dissolved state of the blood, when it appeared on the first or second day of the disorder; but repeated the bleedings afterwards in every case when the pulse continued to indicate it. It was common to see sizy blood succeed that which was dissolved. The disordered appearance of the blood I supposed to be an effect of a certain action of the blood-vessels upon it. The presence of petechiæ did not deter me from repeating bloodletting where the pulse retained its fulness or tension.' And he affirms that both petechiæ and vibices disappeared in various cases after bleeding. This plan he often pursued through the fifth and even the seventh day, in the course of which period from 100 to 120 ounces of blood were frequently taken away by six or eight applications of the lancet.

His purgative plan was not less alert. Ten grains of calomel and fifteen of jalap were the force with which he opened his remedial attack, and which he repeated every six hours till the alvine canal was sufficiently evacuated. This mode of treatment, he tells us, he was led to by accident; and with it he became as successful as he had been unsuccessful under the tame and more established method.

Yet it is the boast of those who have pursued this tamer, and formerly more established method, that though less striking it has in the general balance of the account proved more salutary than the formidable plan of their antagonists.

There is not, however, necessarily any opprobrium medicorum in this discrepancy; for it is probable that in different situations, or under different circumstances, both plans have been equally judicious and equally successful; for we have seen that the disease, under different incidents and coadjutants, has exhibited every variety of violence, and inclined to almost every variety of febrile type. Where there is not much impetuosity in the onset, no great derangement or prognostic of inflammatory congestion in the larger viscera; where the remissions are regular and the epidemy is pretty uniform in its character; large and repeated bleedings, as a general rule, must prove mischievous. They will not shorten the period of the disease, but they will convert the remittent into a continued fever; and we shall in the latter stage of its course stand woefully in need of that strength which we shall have squandered away at first, if we have commenced with profuse venæsection.

On the contrary, if the disease make its incursion with great impetuosity; if the pulse be full and strong; or even if it be only hard, and there be great tendency to inflammatory congestion in any of the larger organs, as the head, the chest, or, as is far more common, the stomach, the spleen, and the liver; we cannot well be too bold both in bleeding and purging; and the plan laid down by Dr. Rush is by no means an exaggeration of what ought to be pursued. It may be that eight-and-forty hours, or even twenty-four are the whole we have to work in; and unless we, so to speak, can stifle or lay prostrate the sensorial power, and thus completely break down the inflammatory diathesis by debilitating and relaxing the living fibre or solidum vivum, rather than by diminishing the moles movenda, the organs mostly affected will, in all probability, become gangrenous, in a day or two the oppressed blood-vessels will give way, and we shall have a chlorotic or livid skin, cold extremities, black vomit, and all the other apparitors of death, before the tamer plan of aperients and diaphoretics could have time to produce the slightest impression on the system. Generally speaking, it will be best to bleed in an erect position; for the sensorial excitement, which is what we are principally to aim at, is cut down by syncope which an erect position will soonest induce, and we may hence save the expense of several subsequent bleedings.

There is no doubt that, by a practice thus active and resolute, very vehement attacks of the yellow fever have sometimes been subdued in a few days. But let not those who have thus triumphed conceive that by the same process they would as soon put to flight less violent incursions of the same disease that have been healed in a different manner; for the more acute the disease the shorter its duration in most instances; and hence, had no medical treatment whatever been resorted to, the fever might have run through its course whether fatally or happily in a less period than if it had commenced more leisurely and insidiously. Yet it is very far from being always true that an early return to health is the consequence of this daring practice, however judiciously it may be had recourse to, and though it may have been the only means of rescuing the patient from death; for the double debility induced by

the disease and its remedy have often laid a foundation for dropsies and other cachexies which have required years to master, and which have sometimes never been mastered at all.

Dr. Pinkard, in his Notes on the West Indies, has given a very interesting description of his own sufferings under this disease, and of the remedial process to which he had recourse. His attack commenced in the more common manner, slowly and insidiously, and demanded eight or nine days to reach its acmé. His head, stomach, and at last his bowels, were severely affected, especially the first; but his intellect continued sound, and, though the symptoms were vehement, there seems to have been little tendency to that violent visceral inflammation which in the stage of debility is so apt to produce gangrene; and consequently he had no black vomit. He lost twelve or fourteen ounces of blood at the commencement of the disease, and took a strong dose of calomel, which considerably relieved the pain in his head and eyes, and diminished the restlessness; but the thirst, heat, and dryness of the skin, were still intense; and his weakness became extreme. Affusions of cold water, old hock, opium, and bark, were made use of in profusion, and each seemed to afford great relief. Yet on the subsidence of the fever he represents his feebleness as most deplorable, and such as it appeared impossible to recover from. Here a mere use of the lancet could have been of no avail, and, had not the author most judiciously forbade its further employment, in all probability he would not have been the historian of his own case.

Mr. Pym speaks with a very just discrimination on this subject, in observing that while the Bulam fever, or the disease in its most violent attack, is relieved by free venæsection, the yellow fever, more properly so called, from the brighter hue on the surface, or, in other words, that which is slighter in its incursion, will not often endure the lancet. Dr. Musgrave's statement seems to oppose this assertion; for he distinctly tells us, that blood-letting in both forms is our sheet anchor; the only pillar on which we can securely rest any hope of extensive success. The Antigua fever seems to have exhibited great severity in most instances, and hence called for a courageous course of practice, with perhaps few exceptions. Yet the following paragraph proves that it did admit of exceptions, and softens down almost to unanimity a clash of opinions and mode of cure, which after all is more ostensible than real. 'We have repeatedly,' says he, 'with success taken upwards of forty ounces of blood at one bleeding. With equal success we have in several cases renewed the bleeding up to the third, and even fourth time; but, generally speaking, those that require such reiterated evacuation, evince an obstinacy not likely to admit of a favorable result, under any mode of treatment. It must also be remembered that every one who applies for assistance is not alike able to bear this liberal depletion.'

The reader will have observed that Dr. Good, throughout the whole of the extract that we have given, assumes an essential identity in different fevers, or in fevers that go under different denominations, and imagines their varieties to be rather incidental or circumstantial than dependent upon varieties of general excitant. It will further have been observed that his opinion on the subject of fever's requisites, in the way of treatment, is that endemic characters and epidemic peculiarities, and other particulars which regulate the degree of force or vehemence with which the disorder makes its attacks, are to be taken into account in the regulation of practice, rather than the name or abstract peculiarities of the distemper itself. In these assumptions and inferences we entirely accord, and are disposed to think that, had they been more generally admitted and acted upon, much of mere verbal controversy might have been saved; as, however, the subject of yellow fever, and the question of its specific character and contagious quality, are still interesting and unsettled, we shall, previously to the conclusion of the present section, extract Dr. Gregory's succinct and able account of the matter, in order that the reader may be furnished with two of our best authorities, that have taken the pains to concentrate the scattered accounts, and reconcile the discordant opinions of those who have investigated the subject. We may first take occasion to say that the reader will find the topic handled in a very able manner by Sir Gilbert Blane, in his Elements of Medical Logic. Dr. Gregory himself speaks of the essay to which we now refer as containing a very luminous view of the yellow fever question, and one which almost precludes the possibility of future ambiguity. The section of Dr. G.'s remarks on the yellow fever is as follows:—

Most of the genuine febrile diseases of hot climates appear to have a bilious tendency. Both the inflammatory and the intermittent and the remittent endemics of those countries are frequently accompanied with a yellow color of the skin, and other symptoms, supposed to denote that the functions of the liver are materially disturbed. This is particularly the case in the West Indies, and the common fever of the country is, on that account, known under the familiar appellation of yellow fever. Into the symptoms and treatment of these forms of disease, however, it is not my intention to enter. They are noticed only in order to contrast them with the epidemic yellow fever, such as that which raged in the West India Islands and at Philadelphia in 1793; at Cadiz in 1800; at Malaga in 1803; at Gibraltar in 1804 and 1813; and again at Cadiz in 1819. As this particular form of fever has been observed in all these situations to exhibit very much of the same defined characters, and as it presents some peculiarities which may distinguish it from other epidemic fevers, I shall give a short account of its symptoms and progress, of the appearances found on dissection, and of the most approved systems of treatment.

The attack of the epidemic yellow fever is ushered in, in the usual way, by languor and rigors. There is sometimes a peculiar dejection of countenance observed, with a remarkable aversion to the least motion; at other times there is an appearance of inebriation. The face is flushed; but the most prominent of the earliest symptoms is head-ache, of a very peculiar kind

It is exceedingly severe, and referred to the forehead and bottom of the orbits. The eyes appear dull, glassy, suffused, and protruded. The tongue is at first furred and moist, and trembling, but by degrees it becomes dry and black, or sometimes of a fiery-red color. The heat of the skin is but little increased. The patient sometimes lies in an almost insensible state, but extreme restlessness has also been noticed.

To this succeeds the second striking feature in the symptoms of the disease, great irritability of the stomach. The matter ejected is very seldom bilious, or, if it is so at first, it speedily loses that character. For the most part it is slimy and tasteless, and adheres in small flakes to the sides of the containing vessel. As the disease advances, it assumes a dark color, and comes to have the appearance of coffee-grounds. This is the vomito prieto, the black vomit, which may be considered the characteristic feature of this disease, as much as buboes and carbuncles are of the plague. The dejections have a tarry appearance. There is often noticed a total suppression of urine, which, like the black vomit, is a fatal symptom. Hiccough, hæmorrhages, and petechiæ, have been observed in some cases, even from an early period.

I have retained to the last the mention of that symptom which gives name to the disease—yellowness of the skin, but it is not of that importance that might have been anticipated. Many cases indeed run through their whole course without exhibiting it; but when it appears early, or when it assumes a leaden or livid cast, it is to be considered an unfavorable symptom. A few other peculiarities in the disease are all that remain to be noticed. The yellow fever is occasionally attended with an ulcerated state of the throat. A fatal termination has often happened in the most unexpected manner, a very singular remission of all the symptoms taking place about sixty hours from the first attack, and raising hopes which are soon to be disappointed. Death is sometimes observed to be preceded by a low muttering delirium; at other times the patient has sunk exhausted, but with the intellect quite unimpaired.

The usual duration of the yellow fever is from five to seven days. If the patient passes the sixth day without the recurrence of black vomit, or suppression of urine, his chance of recovering is much increased; but typhoid symptoms occasionally supervene and prove fatal. Relapses in this disease are very rare.

Upon dissection very few appearances present themselves which can be considered as throwing light on the pathology of the disease. The body has been observed speedily to become livid. Yellowness of the skin has sometimes been first noticed to occur after death. A state of turgescence of the cerebral veins has been described, and occasionally there has been observed a peculiar redness of the inner coat of the stomach. The gall bladder is generally found distended with dark and viscid bile. The structure of the liver is not found to be altered. It sometimes assumes an ash color.

Such are the most usual symptoms of the yellow fever. They will be seen to bear some resemblance to those of the plague, and the analogy between these diseases has been urged with much force by John M'Grigor. A more important analogy may be traced between the epidemic yellow fever and the genuine typhus fever of this country; and there can be no doubt that the former bears the same relation to the endemic fever of the West Indies, that typhus does to the common synochus of Europe. It is probably called therefore the typhus icterodes. The cause of the yellow color of the skin in this fever has been made a subject of enquiry. By some it has been attributed to disordered function of the liver, by others to bile absorbed from the intestinal canal, without hepatic derangement. Sir Gilbert Blane has thrown out the idea that it may be owing rather to a depraved state of the red globules of the blood. In whatever way this question may be decided, it is perfectly clear that the state of the biliary organs has very little to do with giving a character to this formidable disease, which is to be viewed as one of the most aggravated forms of continued fevers. In respect to mortality, the yellow fever may even take precedence of the plague. At Gibraltar, in 1804, the disease raged among the inhabitants uninfluenced by any distinctions of age, sex, or condition. The deaths amounted to somewhat more than one in three, a proportion, according to Sir Gilbert Blane, considerably above the devastation of the pestilence of the Levant.

The treatment of the epidemic yellow fever is a point which has attracted great attention from all classes of enquirers; but their observations tend only to show that it is a disease of so singularly malignant a nature, as, in a large proportion of cases, to bid defiance to all the efforts of art. This is particularly the case when the disease first makes its appearance in any town or district. The peculiar combination of circumstances, whether in respect to local situation, or of the state of the atmosphere, or of the constitution of the inhabitants which gives the peculiar feature of malignity to the symptoms of the disease, operates also against the practitioner, and deprives him of all his most powerful means of combating fever. The severe head ache, which characterises the early stages of the disease, naturally suggested blood-letting as a probable means of relief, but experience has proved that, though occasionally, it is not generally beneficial. The blood, when drawn, separates very imperfectly; upon exposure to air it does not acquire its usual florid color, and scarcely ever exhibits a buffy appearance. The great object which it is found necessary to keep in view, in the treatment of the disease, is the allaying that excessive irritability of the stomach which leads to the black vomit. Calomel given at first in a smart dose so as to operate freely as a purgative, and repeated in smaller doses at intervals of three or four hours, so as to keep up this effect, was the most approved practice among the English practitioners at Gibraltar in 1813. Along with calomel were occasionally united aloes and gamboge. In the exibition of these medicines no time was to be lost, for it was only by their speedy and full effect that the

prevention or relief of the vomiting could be insured. Pediluvia and tepid sponging were found to be beneficial. Under certain circumstances the warm bath even was administered with good effect. Cold applications to the forehead and hands occasionally served to relieve the urgent head-ache. When the powers of life appeared to fail, it is unnecessary to say that stimulants and cordials were had recourse to; subacid drinks were given, and a strict antiphlogistic regimen pursued throughout the whole disease. The same rigid attention to diet and regimen were required during the period of convalescence.

I have stated that among the points in dispute regarding the yellow fever, is the question of the identity of the epidemic yellow, or Bulam fever, with the endemic fever of the West Indies. Upon this question an opinion has already been given. The other topics of controversy are, first, whether the disease be always imported, or whether it can ever be generated by a combination of common or endemic causes; secondly, whether, being once received into a town, it propagates itself by contagion; and, thirdly, whether those who have passed through the disease are susceptible of it a second time. These are all important questions, the replies to which are not so obvious as to that which has already been under discussion, and they involve the most difficult part of the controversy.

The first question is undoubtedly one which should be answered with some caution. Many circumstances connected with the early appearance of the epidemic yellow fever at Philadelphia in 1793, and at Gibraltar in 1804, strongly favor the idea of its having been in those situations an imported disease. Several other facts, however, might be adduced which militate against the universality of this doctrine; and there appears nothing inconsistent in allowing that, under peculiar circumstances, the genuine malignant yellow fever may be engendered by a combination of endemic causes. With regard to the second question, no reasonable doubt can surely be entertained by any candid, intelligent, unbiassed man, that this disease, being once received into a town, is contagious. The evidence in favor of this opinion is certainly as strong as for that of the contagion of typhus or of plague. Whether the yellow fever bears the greater analogy to the former or the latter of these diseases may indeed be disputed. We may hesitate, that is to say, whether the contagion of yellow fever be common or specific; but that the disease is propagated by contagion of some kind cannot be questioned, after the ample experience which has been had, both in America and Europe. If any doubts could have been entertained while the disease occured only in the West Indies, in consequence of the resemblance of the epidemic to the endemic fever of those islands, they must have yielded to the obvious arguments suggested by its appearance in Cadiz and Gibraltar. The contagious nature of the disease, it may be remarked, is a perfectly distinct question from that of its foreign or endemic origin.

Some of the laws of contagion of yellow fever appear to be ascertained with tolerable accuracy. Its latent period varies from two to eight days. Ten days are, I believe, the longest period recorded of yellow fever appearing after the exposure to the contagion, and removal to a freely ventilated atmosphere. The contagion of yellow fever has a peculiar range of atmospheric temperature, but on a higher scale than that of the plague. It has never been known but in those countries and at those seasons, when tropical heats, that is, of eighty degrees of Fahrenheit, or upwards, prevail. It never fails to disappear as the winter approaches. It is certainly a singular circumstance in the history of the yellow fever that it has never been seen, except in one instance, but on the shores of the Atlantic Ocean.

The last circumstance which it is of importance to notice, in the history of the yellow fever and the laws of its contagion, is the question whether it can be taken a second time. The answer is a very short one. Although a few well-attested instances to the contrary have been recorded, still a most extensive experience has satisfactorily proved that the immunity from second attacks is nearly complete, and that it forms one of the most striking characteristics of this remarkable disease.

Hectic fever.—This is the last species in Cullen's order of febres; but it is introduced improperly, as it varies much from all other kinds of idiopathic fever in being without that symptom which is so remarkably characteristic of the febrile condition, depression of animal power; for it is observable that from the first the subject of hectic fever has for the most part an alertness and springiness of feeling which is often, indeed, mournfully in contrast with the wearing and wasting character of the disease. Hectic also is for the most part decisively the product of topical affection, which presents another inconsistency in the classification, inasmuch as Cullen's theory supposes genuine fever to be a general, not a local, disorder.

Symptoms of hectic fever.—This is essentially a remitting fever, having its remissions and exacerbations fairly marked; these occur twice in the day for the most part, the first about noon the other about six o'clock in the afternoon; and which last exacerbation is certainly the most considerable. Hectic fever is prominently marked by a circumscribed red spot on the cheek alternating with paleness. The tongue is clear and red, and, as we have above observed, the animal powers are, comparatively with other febrile states, free from oppression. The brain does not appear to be affected in hectic. The appetate is not necessarily impaired as in other kinds of fever. Thirst is not so urgent. Emaciation is for the most part extreme, and towards the last a diarrhœa almost invariably takes place. But the great characteristic symptom of this malady, or rather of this index of other malady, is the colliquative sweating which takes place in the night and continues till the morning; so that the patient, when he is about to rise, finds himself bathed in perspiration, which perspiration for the most part is principally conspicuous about the head and neck, and breast and shoulders, or at any rate it is not diffused over the whole body so generally as the sweat which terminates the paroxysms of other fevers.

Such are the characters of hectic when fully marked, and when attendant upon some wasting process of disorganisation that is going on in the system, especially an ulceration of the lungs. When, however, in the course of mentioning other maladies, we state that hectic is an accompaniment, it must not be supposed always that we speak of the symptom in this unequivocal and extreme manner. In the preliminary remarks on the nosology it will be seen that we consider hectic to be a mode of disordered manifestation very common to scrofulous or lymphatic ailments, and occasionally, when the constitutional tendency has this verging, if we may so say, more or less of hectic irritation will easily be induced by any circumstance which excites morbid irritation in the frame.

With respect to the treatment of hectic nothing requires to be said in this place, since its management is the management of the disease upon which it depends. Indeed, as decidedly a symptomatic disorder, and as widely different from all other disorders to which the term fever has been appropriated, we only introduce it here in conformity with the nosological arrangement we have adopted. We shall have again to allude to it especially under the head of pulmonary consumption.

344. Order 2. Inflammation. For some remarks on the general pathology of the inflammatory state we refer to our introductory proem, and the farther consideration of this state will be found in the article Surgery. It is only for us, in the present instance, to delineate the general symptoms of inflammation, mark its diagnosis from other diseases, and give an outline of the principles which should regulate its treatment. We shall then be prepared to go through the several maladies contained in the order.

Symptoms of inflammation.—It will be seen, by turning to the nosology, that topical pain with synochal fever, lesion of function, and the blood exhibiting upon being drawn the inflammatory crust, are considered by Cullen as the main characteristics of the state now to be commented on. But there is an incorrectness in these assumptions; for the local disorder shall sometimes, as in the instance of what is called passive inflammation, be accompanied with a sympathetic fever, which has not a synochal aspect; and the buffed blood is sometimes present when no inflammation exists, while it is occasionally absent under the presence of inflammation. We may remark by the way, and before we proceed in the delineation of symptoms, that buffy crusts on the surface of blood should be always recognised with some reserve as an index of the inflamed state; for, as Mr. Thachrah very properly remarks, in his excellent treatise, it is sometimes rather the indication of very different circumstances from those of excitement. There is a good deal of difficulty connected with the theory of buff on blood, but one particular connected with its rationale is pretty clearly made out, and that is, that the slowness with which the separation takes place of the constituents of blood in some measure regulates the quantity of buff. Now this separation is effected more or less tardily as the components of the mass are more or less intimately combined; and when the blood is in a condition of more than common thinness, as is the case under several circumstances of extreme debility and lowness of vital power, the tardiness of the coagulation will cause the appearance on the surface of buff, which is then any thing but a token of inflammation. We merely mention this particular by way of caution against hasty and unqualified inference, and not at all with a view to invalidate the criterion now under remark; for certain it is that, cæteris paribus, buff on blood must be considered as proof of the presence of inflammatory excitement.

Pain, heat, hardness and quickness of pulse, with external redness and swelling, if the parts implicated are so superficial as to be obvious to the senses, are noted down by authors as indices of inflammation. The first symptom, pain, would not seem of difficult explanation, when we recollect the distension of the parts engaged with inflammation: but, besides the mechanical source of pain, if it may be so expressed, there is an increased sensibility referrible to the augmented excitement, and connected with the laws of vital influence. Pain, moreover, often exists without inflammation, so that its kind rather than measure is to be taken as the characteristic symptom—it is what is called lancinating and acute in the first stages, and afterwards throbbing or pulsatory. It is also increased by pressure, should the organ affected be so situated as to be within the reach of pressure; whereas pains arising from other sources are oftentimes mitigated by pressure.

Heat is a symptom of inflammation, but not perhaps necessarily or characteristically so; when it takes place it is in superficial parts, or in parts at a distance from the centre and source of circulation, and it is, like the pain itself, partly referrible to increased nervous excitement, and partly to be attributed to the more than ordinary quantity of blood rushing through the vessels that are implicated in the disorder.

Increased redness is the necessary consequence of inflammatory condition; for where more blood is flowing through vessels than they ordinarily convey, and when moreover new vessels shoot out which are immediately supplied with their appropriate fluid, more than common redness must be the result.

Swelling too, or increased bulk, naturally and necessarily grows out of the inflammation, since the distended and newly formed vessels must by occupying space increase bulk; unless where the structure of the part is resisting and not loose, in which case no swelling will be perceptible.

In respect to quickness of pulse, this almost of course ensues from the systematic excitement which the local irritation causes; and with quickness there is for the most part a hardness or wiry feel in the pulse, as if there was a resistance to the velocity and perturbation excited through the mass of circulating blood.

The above are the symptoms of the first stage of inflammation. When the second or suppurative stage is about to commence the lancinating and tight kind of pain becomes changed to a sensation as if of throbbing or beating; a feeling also of fulness takes the place of tightness; the pulse

from being hard and wiry becomes softer and fuller, and when pus is formed to any extent we have almost always the occurrence of rigors.

The third or gangrenous stage is denoted by the sudden cessation rather than change of pain, while the pulse instead of becoming full as in suppuration acquires a very great rapidity, and occasionally becomes irregular; the patient although he may express himself relieved, and fancy that all is going on well, soon loses the natural fulness of feature and ordinary expression of countenance, and also feels incapable of muscular exertion; in a short time becomes wandering and delirious, hiccough supervenes, cold sweats break out, and death soon closes the scene. Many are the instances in which from an individual expressing himself relieved and improved, he has become a corpse in less than forty-eight hours; and the medical practitioner ought always to be aware of pronouncing his patient better merely from the subsidence of the pain, while the pulse, instead of coming down to the standard of health, increases in celerity. Rigors then, let it be repeated, are the leading features of suppuration; subsidence of pain with rapidity of pulse marks the commencement of gangrene.

It may be remarked, before we terminate this outline of inflammatory symptoms, that the disorder sometimes instead of tending to suppuration terminates by effusion, as indeed we before slightly intimated when speaking of inflammation in our introductory section; when that is the case rigors do not follow the subsidence of the irritative state, but an approach to hectic manifestation takes place of the primary excitement; when the effusion is of serum one species of dropsy is formed, as we likewise have already noticed, and when it is coagulable lymph that is thrown out adhesions are effected often between parts that were originally in a state merely of contiguity, and a new kind of impediment to function is produced. Thus in the first stages of inflammation of the pleura we have tightness of breathing occasioned by the inflamed state of the membrane, and afterwards we have difficulty in the respiratory process from the two layers of the pleura being glued as it were together, or being attached to the parietes of the chest on the one side, or the surface of the lungs on the other, in the same adhesive or organic manner.

Of the kinds of inflammation.—Phlegmon and erythema, are, it will be seen, the two species marked in the nosology. A phlegmon may be described as an inflammation of a bright red color, of a regularly circumscribed extent, and marked by a general disposition to the suppurative process. An erythema is characterised by a less deep color, by being more superficial and spreading than circumscribed and deep, and by manifesting a tendency first to serous effusion and next to gangrene, rather than showing a disposition to suppurate. Boils are phlegmons, as are the pustules in what are called distinct small-pox. Scarlet fever, measles, and the confluent small-pox, more especially the first of these maladies, are rather instances of erythematic than phlegmonous inflammation. Phlegmons are not confined to membranous expansions, but are, as above intimated, found to penetrate muscular or fleshy substance, while erythema is rather a disorder of membranes.

Inflammation, however, it should be remarked, is not only modified by the constitutional energy of the individual, and the texture which it implicates, but it has a dependence further upon the nature of its exciting source. Thus the inflammation of rheumatism is different from ordinary inflammation, though the habit of the sufferer be the same in either case, and even though the texture implicated be the same; thus the erythema of scarlet fever and that of erysipelas are in one respect alike, in another dissimilar; again scrofulous and venereal inflammation differ from common inflammation in several particulars as in other places will be duly noticed, so that, in considering both the symptomatology and the rationale of the inflamed state, varieties from exciting sources and constitutional predisposition must always be taken into the account.

On these sources of inflammation, we may extract the following statements from Dr. Gregory.

1. Mechanical and chemical irritants. The phrenitis of infants has been traced to the irritation of teething, gastritis to poison, interitis to the presence of hardened fæces; nephritis to calculus in the bladder; ophthalmia to dust and sand; erysipelas to leech bites, or the distension of the skin from dropsy.

2. Cold is the most important of all the exciting causes of internal inflammation. There is scarcely a form of it that does not occasionally owe its origin to cold, and many inflammatory affections, as rheumatism and pleurisy, have no other cause of the smallest practical importance. The period of time that elapses between the application of cold and the occurrence of inflammatory symptoms is subject to great variety. In the case of sore throat, it often follows in the course of a few hours. In that of acute rheumatism a week or even a fortnight has been known to elapse. In what manner cold operates as the cause of internal inflammation has been a constant subject of enquiry with all pathological writers, but it is still involved in great obscurity.

3. Some forms of inflammation, which to a superficial observer might appear to arise without any assignable cause, have their origin in a peculiar state of body, the nature of which is not always understood, but which the older physicians supposed to consist in some morbid state of the fluids of the body. This piece of pathology is exemplified in the phenomena of gout; to the inflammation of absorbent glands occurring in scrofulous children, on the approach of winter; and in the pustular eruptions to which young persons are subject about the age of puberty. The presence of fever unquestionably leads to local inflammation, and hence it is that, in the progress of typhus, thoracic or abdominal inflammations so frequently supervene.

4. The presence of a morbid poison in the system is a frequent occasion of internal inflammation. This principle is amply illustrated in the phenomena of the plague, small-pox, measles, and other exanthemata. It is equally exemplified in those of secondary syphilis, where the inflammation of the fauces, or of the iris, or of the

joints, is obviously attributable to the presence of a morbid poison. Closely allied to this, in a pathological view, is the important, but well ascertained fact of the origin of many inflammatory affections from contagion. There is a species of contagious catarrh. Two species of cynanche are contagious. There is a contagious form of ophthalmia. Erysipelas is contagious under certain circumstances; so in all probability is dysentery There is reason to suspect that one of the forms of peritoneal inflammation is occasionally propagated in the same way.

5. The last cause of internal inflammation which it will be necessary to notice in this general view of the subject is metastasis, or the translation of inflammation from one organ or structure to another. This is a very curious point in pathology, sufficiently established indeed, as a mat- of fact, but the reasonings concerning which are hitherto very obscure and imperfect. It is exemplified in the ophthalmia which succeeds gonorrhœa; in the inflammation of the testicle which succeeds the mumps, in the inflammation of the pericardium which succeeds rheumatism. In what manner the metastasis is effected has never yet been developed. It appears, however, that to sympathy from similarity of structure, something may be referred; for in almost all cases of metastasis it will be found that the structures primarily and secondarily affected have an affinity to each other.

In the treatment of inflammation it will be of course right to consider the exciting cause, the period of the disease at which we are called upon to attempt our remedial measures, the degree of force by which the inflammation is characterised, and the structure and habits of the part inflamed.

In acute, or active, or as it has been called sthenic inflammation, the immediate indication is of course to lessen the action of the vessels, and diminish the quantity of blood flowing through them; and to effect this purpose venæsection, purging, refrigerants, sudorifics, emetics, and counter-irritants are had recourse to. Some have said that the three indications, which the treatment of the most sthenic inflammation involves, are to reduce action, to promote absorption, and to restore tone. In a MS. course of lectures which is now lying before us we find the following statements of opinion in reference to these indications. 'I would again call to your attention the principle previously inculcated, that while the most passive or atonic kind of inflammation supposes commotion and inordinate irritation, which we are called upon to subdue, on the other hand the most sthenic or tonic, if it may be so called, implies vascular debility. How, I would ask, is it possible for more blood to be forced through vessels than nature ordained them to convey, without such admission and transmission, being occasioned by a deprivation of tonic or resisting power to vis à tergo impulse; it may have been induced by that impulse, I grant, and have already indeed stated that it is so, but still the weakness is present, and part of the curative means should have regard to its presence. When then I place blood-letting, as it ought to be placed, at the front of remedial measures for the subduction of the inflammatory state, I would say that in thus necessarily withdrawing the vis à tergo impulse, we must be careful that we do not too much add to the weakness of the capillary vessels, which constitutes one of the links in the chain of the inflammatory state.' 'Again,' the lecturer goes on to say, 'it will be had in recollection, that I have intimated the impossibility of simple reduction of an inflamed condition of parts. The change which inflammation creates implies a degree of disorganisation; there is the production of new fibre and new vessel, and there is effusion either of lymph or of serum, so that the process of cure when in the most immediate and simple way implies some degree of absorption; and if we carry our weakening measures too far we may be likely rather to facilitate and encourage the tendency in some species of inflammation to effusion. Carrying these principles out to too great a length, some practitioners have proscribed blood-letting altogether, and Dr. Maclean has published a volume full of cases, in which inflammation was successfully treated by calomel and opium, omitting altogether the use of the lancet; but this appears a dangerous extreme on the other side, and there are many cases in which it would seem next to madness to attempt the cure of the disorder without even very considerable venæsection.' Thus far the lecturer, who, it will be seen, argues on the assumption of inflammation being constituted of weakness of vessel as well as of inordinate excitement; and, although we may not subscribe to his theory, or comply altogether with his practical principia, we may at any rate take from him the hint that the powers of the system, as well as the force of the disorder, ought to be taken into our calculation, when we are using the lancet to subdue inflammation.

It is a most important observation of Dr. Gregory that to a certain degree the part inflamed affects the treatment. 'Inflammation of a serous membrane,' says this very able writer, 'demands the copious and rapid abstraction of blood. That of mucous membranes does not bear the same extent of evacuation, nor does it so often require it. Erysipelatous inflammation is often successfully treated by bark and acids. Rheumatic inflammation is often under the control of certain drugs which have no effect upon, or which prove absolutely prejudicial in, common inflammation, I mean colchicum and opium.' In the latter clauses of this paragraph Dr. G. alludes, however, rather to the kind of disorder than to its locality; and besides the remarks go beyond the question of blood-letting, but they are altogether so important, and so deserving of practical recognition, that we could not resist the temptation of transcribing the whole.

Immediately upon an impression being made upon the system by large blood-lettings, in some cases of internal inflammation, Dr. Armstrong and others have recently recommended the practice of administering pretty considerable quantities of opium, such as three grains of the powder; and Dr. Uwins, in his recent treatise on affections connected with indigestion, proposes to explain the good resulting from this practice in the following way. It would seem that opium exerts a particular effect upon the small capillary system of

vessels which is proved by the tendency it has to lock up secretions. This effect is contractile, and we may then suppose that the medicine by contracting or lessening the diameter of the capillaries may prove preventive of that rush of blood again into them which is so apt to succeed to depletion of vessels. Whether this or any other principle be that upon which the good of opium after blood-letting actually depends, may be a subject of dispute; but, if more extended observation confirms the rectitude of the practice, it will not be right to wait for settling the rationale, before we adopt the measure; and, so far as our observation has gone, we are inclined to think very highly of it.

Purging is another important principle in the treatment of inflammation. By producing catharsis, we certainly accomplish a two-fold object, we call the action of the vessels away from the part affected, and diminish the irritative fever which has been set up by the local disorder. Some kinds of purgatives indeed as in the instance of elaterium by occasioning a general nausea, effect a sort of collapse over the whole frame, or to make use of a terminology that does not imply hypothesis, cause such a general impression upon the system as to abate the force of the disorder. In some cases it is desirable to accomplish this effect without expenditure of blood; and, when these cases occur, the medicine just named may be occasionally employed with happy effects. How far purging is requisite and admissible in inflammation of the bowels will afterwards be matter of enquiry.

Sudorifics are employed as anti-inflammatory measures with occasional good effect, by throwing the actions and the fluids of the system out upon the surface: these medicines, as mentioned under the head of fever, abate inordinate heat, divert the current of blood from the affected organs, and tend generally to equalise the circulation. Some medicines in the class of sudorifics, when employed in rather large doses, excite an emetic or a nauseating effect, and when they do so their modus agendi may be partly similar to the sort of purgation to which we have above referred.

Another mode of abating inflammatory action consists in the administration of those medicinals which, under the supposition of their possessing the faculty of reducing inordinate irritation, in an immediate or direct manner, have been termed sedatives; the term is however vague, or at any rate it is only expressive of an effect, and does not convey any precise notion of agency. Foxglove and the hydrocyanic acid may be instanced as two of the most conspicuous medicinals of this class.

Counter-irritation is the last means here to be noticed of remedying inflammation. It is a law of the system, that one irritation tends to modify and often to mitigate another, and it is partly in conformity with this law that epispastics and rubefacients are made use of as anti-inflammatory measures. Blisters to the back of the neck will often relieve an inflammation of the tonsil glands, and so forth. It is in the general way expedient that the high excitement connecting itself with the first stage of active inflammation be in some measure subdued before these counter-irritants are resorted to; otherwise by introducing a new excitant to the already morbidly excited frame, we may increase the evil that we wish to subdue. It is for example but seldom, unless in cases of long continued or chronic inflammation as it is termed, that blisters are applied with propriety before the use of the lancet.

On the subject of chronic inflammation we shall take the liberty of extracting the following remarks from Dr. Gregory, premising that the condition of vascular disorder, which this term is meant to denote, is somewhat obscure; indeed, when it is considered how very shortly inflammatory action produces disorganisation—occcasions the formation of new vessels—the effusion of coagulable lymph, and the consequent change of structural circumstance in the parts implicated, we cannot well imagine the presence of the disordered state, during any length of time, without the consequences now referred to; still there is, at times, a species of vascular irritation of a passive and chronic nature, which demands to be recognised, whatever terminology we may apply to the state. Dr. Baron, in a recent work of much ingenuity, has objected to the generally received principles of chronic inflammation, and has suggested whether the lymphatic system may not have much more to do than the blood-vessels in effecting those structural alterations which are usually referred to inflammatory action of a continued kind, whether of a common or specific character. Some of the continental pathologists have in part conjectured, and endeavoured to establish, the same principle of action; and have pointed out the lymphatic, and the sanguiferous capillaries, as the chief seats of those irritative actions which are usually designated chronic inflammation: the subject, however, is altogether somewhat obscure, and still open to farther research. In the article Surgery we shall have more particularly to refer to this subject, and shall here limit our disquisition to the above mentioned extracts.

Chronic inflammation, says our author, occurs frequently, and in almost every variety of structure; in the lungs, where it lays the foundation of consumption; in the brain, liver, spleen, and kidneys. All the serous and mucous membranes of the body are subject to it; and, in many cases, it proves a most formidable affection, as in chronic dysentery, and catarrhus sinilis. The substance of muscle appears to be the seat of inflammation in some forms of chronic rheumatism, the frequency of which disease shows that the fibrous membranes are in like manner affected. The skin is, of all textures, the least liable to chronic inflammations. This state of disease falls also within the observation of the surgeon. Gleet, inflammation of the prostate gland, scrofulous enlargements of absorbent glands, chronic ophthalmia and ozæna, or the chronic inflammation and ulceration of the schneiderian membrane, may be taken as instances.

One of the circumstances most deserving of attention in the pathology of chronic inflammations is, that it is sometimes a primary, and at other times a secondary, affection. By this latter term it is intended to denote that it succeeds

acute inflammation; and this is the most common form in which it appears. It is thus that it occurs in gleet and dysentery. But at other times it is not preceded by any symptoms of active inflammation. It begins almost imperceptibly; and its advances are slow, often exceedingly insidious, being unaccompanied by any symptoms which could betray, even to the experienced practitioner, the existence of such a disease. No where is this better exemplified than in the case of some forms of peritonæal inflammation; but the same thing has been observed also in cases of chronic inflammation of the membranes of the brain, and even of the heart itself. In these instances not only are there wanting all local symptoms of inflammatory action, but there are not even any constitutional symptoms; at least none of sufficient importance to attract attention. This, however, it must be confessed, is comparatively a rare occurrence; and it is much more usual for chronic inflammation, both primary and secondary, to exhibit local and constitutional symptoms; less in degree, but the same in kind, with those which accompany acute inflammation.

The local symptoms produced by chronic inflammation vary of course with the part affected. Sometimes, as in chronic laryngitis, there are local symptoms, but no affection of the constitution. When the general system is implicated, the symptoms are usually those of fever. The pulse is quickened; there is a white tongue, thirst, and some degree of restlessness. Occasionally, however, in a state of chronic inflammation, the tongue is clean, there is no thirst, but the pulse is feeble and languid, the extremities are cold, and the slightest exertion occasions fatigue, generally uneasiness and pain across the loins. All these symptoms mark a state, not of fever, but of atony and debility. The term asthenia has been applied with much propriety, by some pathologists, to express this state of the general system. Many of the protracted cases of bronchial inflammation, particularly those which occur in old people, exhibit, in the greatest perfection, the characters of asthenic inflammation.

The causes of primary chronic inflammation are involved in much obscurity. There is reason to suspect that cold has sometimes induced it; or mechanical irritation, as in the case of chronic inflammation of the brain, from spiculæ of bone; but it is seldom that we can attribute the disease to so obvious a cause. A scrofulous habit of body appears to favor the disposition to chronic inflammation; but it often occurs where it would be mere hypothesis to attribute it even to that obscure source. What the particular state of body may be which leads to the affection, in such cases, is in all probability inexplicable.

The nature of that action of vessels in which chronic inflammation consists has been long an object of research. By some it has been defined to be that state of increased action of vessels, which is neither so far subdued as to tend to resolution, nor so violent as to form abscess; but this goes only a little way in explaining the difficulty. From the appearance of the eye in some cases of chronic ophthalmia, and from the effects of the juvantia and ledantia in this and many other instances of chronic inflammation, it would seem probable that a relaxation of vessels prevails, rather than any increase of their action. It must be confessed, however, that this object of enquiry is obscure; and perhaps the truth, if it could be ascertained, would be found of no practical application. (Dr. G. here refers to the pathology of the French, and its similarity with the speculations of Dr. Baron.)

The effects, he continues, of chronic inflammation, or more correctly the local appearances presented during the state of chronic inflammation, vary with the texture of the part affected. A simple thickening of structure is a common appearance, both in serous and mucous membranes. Sometimes the thickening assumes the form which has been called tuberculated accretion. In serous membranes it leads to the extensive union of surfaces. Schirrus is generally accounted the effect of chronic inflammation in a glandular organ.

The origin of *tumors* in different structures is a subject that has excited much attention among pathologists. In many cases it is presumed that their growth is referrible to the same action of vessels by which all parts of the body are formed; but in other cases there is reason to believe that they may have had their origin in a state of chronic inflammation of vessels. Closely allied to tumors are tubercles; but the views which are entertained by pathologists of the origin and progress of tubercle will come better under discussion hereafter, when treating of pulmonary consumption.

The last effect of chronic inflammation which I shall notice is suppuration; and it is one of those which we have most frequent occasion to witness in practice. The fact of the formation of purulent matter in cysts and other structures, without any evidence of previous inflammation, was well known to John Hunter, who had particular views of his own regarding it. But they are unsatisfactory, and, until further light is thrown upon the subject, it may not be improper to consider these collections of matter as the result of chronic inflammation.

To some, the subjects which have now been discussed may appear too indefinite and obscure to be legitimate objects of investigation, particularly in an elementary work. To this I would reply in the energetic language of Bichat 'that, in explaining the animal economy, it is doing much to indicate analogies; to show the uniformity of an unknown phenomenon with another about which all the world are agreed. In every branch of science,' adds this author, 'it would be well if the principle were thoroughly appreciated, that nature, greedy of her means, is prodigal of results; that a small number of causes every where preside over a multitude of effects, and the greater part of those about which we are doubtful are referrible to the same principle with others which appear to us evident.'

The treatment of chronic inflammation is very little understood. It is often said that parts which have been much weakened, especially by large bleedings during the acute stage, are liable to fall afterwards into the state of chronic inflammation. We believe, however, that the remark is

not of general application; and that this form of the disease is oftener attributable to a neglect of those vigorous measures which would have cut short the acute state of inflammation at its commencement. Chronic inflammation is almost as much out of the control of medicine as acute inflammation is under it. Nature sometimes works a cure; but in many cases, more particularly of primary chronic inflammation, the prognosis is very unfavorable.

The general system of treatment must depend upon the state of the constitution. Four plans of treatment have been advised, and each has been found serviceable under different circumstances.

1. Where fever is present, blood-letting, purging, and saline medicines, with a low diet, are to be recommended.

2. Where the pulse is feeble, and there is a decided loss of tone in the system, myrrh, benzoin, the balsam of copaiba, steel, and bark, are unquestionably useful.

3. Where the disease is purely local it is best treated by leeches, blisters, and issues, upon the principle of counter irritation.

4. Where these means fail an alterative plan of treatment may be resorted to. This is done under the idea of giving a new action to the vessels. Upon this principle mercury is employed in the treatment of chronic hepatitis, alkalies in the scrofulous inflammation of absorbent glands, and sarsaparilla and guaiacum in chronic rheumatism.

We are now called upon to follow the nosological order of inflammatory affections, and the first which falls before us for notice is,

345. *Ophthalmia*, or inflammation of the eye. The species of the genus are, it will be seen, ophthalmia membranosa, inflammation of the membranes of the organ; and ophthalmia tarsi, inflammation of the eye-lids.

The eye is a complicated organ, and therefore subject to a variety and complication of ailment, and Dr. Cullen's divisions are by far too general and superficial; most, however, of the minute circumstances and incidents attendant upon ophthalmic irritation will come to be considered under the head of SURGERY, and we shall here limit ourselves to a very cursory notice of the inflammatory disorders which occasionally attack the organ of vision.

The principal points of attack are the tunica conjunctiva, the sclerotica, the iris, and the tarsal glands. Pain, inordinate sensibility to the light, a feeling as if something gritty had made its lodgment in the eye, redness in the parts which are usually colorless, and an increased flow of tears, are the prominent symptoms of conjunctival inflammation. When the disorder is very severe, head-ache, and often of an excruciating kind, accompanies the inflammation; the intolerance of light is extreme, and the inflamed conjunctiva extends to the lids, occasions them to swell, and to pour out a purulent secretion which glues the edges of the lids together; and then the purulent ophthalmia of authors comes to be formed, which, if suffered to run on without interruption, tends to a disorganisation of one or other of the structures of the organ, one of the most common and direct of which is the inflammation extending over the cornea, and, by thickening its coats, destroying its transparency, and of course in the degree of the opacity produced does vision become defective; sometimes, in place of chronic thickening and opacity, actual and open ulceration is formed in the cornea. The iris sometimes partakes of the disordered action, and adhesions are hence formed with the capsule of the lens, or with the posterior layer of the cornea, and more or less of blindness is thus induced. In weak and scrofulous habits the acute state of ophthalmia, instead either of completely yielding or terminating by one or other of these disorganising processes, passes into an indolent or chronic state of conjunctival inflammation, and continues for some time in a very obstinate way, refusing to yield to ordinary treatment.

The causes of ophthalmia are those which either operate upon the organ itself immediately or from without, or those which act sympathetically or intermediately; these are frequently combined in their operation, that is, the external irritants which produce the disease would not sometimes prove of sufficient force, were they not assisted in their influence by the condition of the general system. A pecular poison sometimes seems to engender ophthalmia, as was the case with the Egyptian army; a poison which seems to affect both endemically and epidemically; thus it appears to result from the combined influence of heat and moisture and floating particles of sand in the atmosphere acting in combination with the predisposing circumstances of fatigue and bad living, and having once affected becomes communicable from one individual to another; there does not appear to be any room for doubting that disordered states of the eyes were communicated from our soldiers who returned from Egypt ophthalmically affected, to many of the inhabitants even of this country; in which, of course, the endemic circumstances which had to do in the formation of the disease originally could not have operated.

The ordinary external irritants are changes of temperature, exposure to a brisk and keen wind; blows, and other mechanical or chemical irritants. The internal sources of the disorder are generally deranged states of the digestive organs, produced by intemperance, or occurring more spontaneously, and the presence of some morbid poison as of small pox; translated poison, also, or metastatic action, is to be put down as one of the sources of ophthalmia, manifested in the curious instance of the gonorrhæal discharge ceasing or becoming repelled from its common locality, the urethra, and affecting the eye; in this case the purulent ophthalmia becomes formed, and, although it is not the same matter which is engendered by the new disease with that which has ceased to flow from the urethra, the subsidence of one disorder and the immediate commencement of the other are curious facts in pathology. It has been found that the matter of gonorrhœa, when the disorder is very active and the discharge acrimonious, if applied to the eye will sometimes excite inflammation; and it has

been supposed that in the instances of ophthalmia after gonorrhœa some accidental application of this kind had taken place; but there does not seem evidence sufficient to establish this presumption, and the vicarious manner in which the eye affection occurs is inconsistent with the hypothesis.

The kind of disease to which Dr. Cullen applied the term tarsal is of scrofulous origin, and is very commonly seen in children of a strumous habit. With tarsal inflammation, which extends to the glands and occasions a copious secretion of matter, which glues the lids together, you often see marks of membranous irritation, which in some cases indeed is very severe, accompanied with an increased flow of tears and all the other symptoms and tendencies of membranous ophthalmia; so that the distinction is often an untenable one. Occasionally, however, a chronic, and indolent, and evidently a scrofulous, affection of the tarsi will be present for a length of time without being extended to the actual structure of the eye. There is scarcely a stronger indication of scrofulous diathesis than the condition of eye-lid to which we are now alluding.

The venereal poison, when it affects the eye in a secondary way, most frequently attacks the iris. Iritis, however, will be most properly considered in the article SURGERY, and so will that species of inflammatory irritation which has but of late years been duly recognised as one of the producing causes of amaurosis, which occurs frequently, as a consequence of the intemperate use of the eyes, and in which there is often impatience of light and even an increased secretion of tears without any exterior redness of the organ.

In the treatment of ophthalmia depleting measures will be called for, according to the degree of the disorder, and the condition of the constitution. In violent cases general bleeding, and that copiously, is often demanded. In the milder cases local abstractions of blood, as by leeches and cupping glasses, will be all that are required. In all cases the state of the stomach and bowels must be carefully attended to; for, as we have above intimated, the source of the disorder, or, to say the very least, the predisposition to it, is to be found in a deranged condition of the whole system. Where we are fearful of large detractions of blood, nauseating doses of tartar emetic will be found serviceable in getting under the inflammatory diathesis and the local disorder; and, after the bowels have been evacuated, the combination of calomel and opium, in the small doses of half a grain of each, repeated three or four times in the day, will often prove exceedingly beneficial. The counter irritation of blisters is almost always desirable after the force of the inflammation may be a little subdued by blood-letting, or where the disorder has not assumed a very formidable aspect from the first; and cold lotions, such as a scruple of the sugar of lead to half a pint of distilled water, will assist in the cure.

When inflammation of the eye has become chronic and indolent, tonics are often required, together with topical applications of a more astringent kind, such as the white vitriol (the sulphate of zinc), a scruple or half a drachm of which may be dissolved, for a lotion, in half a pint of water, or alum solutions, or aqueous or vinous solutions of opium, may be dropped into the eye. In these cases attention to visceral states is also absolutely necessary, as it is also in the strumous or tarsal affection to which we have above alluded, and for which the best local application is unquestionably the citrine ointment, the unguentum hydrargyri nitratis, with which the lid should be penciled every night, after the subject of the disorder has gone to rest, and closed the eyes; for, if used while the eye is open, it may stimulate the membranous part of the eye too much, and cause a painful irritation.

346. *Phrenitis.*—Inflammation of the brain. The acute or violent kind of phrenitis in an unmixed form is not of very frequent occurrence, although inflammatory affections of the brain of a less decided character, and less formidable aspect, are not by any means infrequent. Indeed disorders which go under other names, such as apoplexy, epilepsy, paralysis, and hydrocephalus, are often but certain modifications of brain inflammation, and this inflammation is, as we have already seen, a very usual accompaniment of fever.

The following are the characterising symptoms of acute or idiopathic phrenitis. Acute pain, which often begins at the back or hinder part of the head, and at length extends over the whole of the head, flushed face, eyes red and prominent, intolerance of light and sound, the carotid arteries appearing to beat with unnatural energy, furious delirium, the pulse for the most part very quick and hard, and the tongue furred. When the symptoms are more insidious, and the disease is more symptomatic of other derangements, the symptoms for the most part are such as characterise a typhoid disposition.

Causes of phrenitis.—Exposure to the rays of a vertical sun, especially in the tropical climates, will produce inflammation of the brain, at times in an immediate manner. This constitutes the insolation, or coup de soleil, of authors; violent passions of the mind, immoderate application to business or study, external violence, as from blows or falls, repelled eruptions, extension or translations of external erysipelas upon the brain, inebriation, and a disordered state of the first passages or viscera; which last sometimes merely predisposes to, at others actually excites the complaint.

Distinctions.—Some persons have confounded phrenitis with mania, or at least have supposed that, where maniacal excitement manifests itself to a very considerable degree, there must necessarily be inflammation of the brain; there appears, however, to be considerable error in this opinion, and it is an error which may lead to false inference with respect to practice. Phrenitis, we are told, may be distinguished from insanity by the former being necessarily attended with pyrexia, and by its being externally imprinted on the countenance in a way more indicative of vascular fulness. The pulse too is harder and more frequent than is ordinarily the case in mania. From the inflammation of fever

it is to be distinguished by its early manifestation, or by its being synchronous with the general derangement, while the phrenitic symptoms of fever present themselves after the disorder has existed for some time. The powers too in phrenitis are not in that oppressed state that they are in fever.

There is a singular condition of brain, for the most part induced by a long course of inebriation, which, although manifested by a certain kind of high excitation, is still different from phrenitis: the condition of the brain to which we now allude is named in the schools delirium tremens, from the circumstance that, while encephalic excitement is at a very high pitch, there is a trembling and powerless condition of the general system, differing on the one hand from the oppression of fever, and on the other from the excitement of real or high inflammation. It ought always to be the aim of the medical practitioner to recognise these distinct conditions, both of the brain and general system, and not to confound all manifestations of cerebral irritation under the general notion of inflammation.

The student, it has been further remarked, must not expect to find every case of phrenitic disorder marked with unequivocal signs, nor is it very easy sometimes to distinguish the idiopathic from the sympathetic phrenitis; the complaint, moreover, occasionally occurs in the most insidious manner, and if the difficulty of distinguishing abstract or idiopathic phrenitis, from the phrenitis consequent upon fever, should embarrass the young practitioner, let him recollect that this difficulty is not peculiar to the inexperienced; indeed some, as we have already had occasion to intimate, maintain, that no such distinction actually exists. There appears, however, to be one state of brain in fever, another in phrenitis, another in mania, and another in delirium tremens, although the lines of demarcation are not always to be traced: disordered conditions being often mixed and modified to an extent which defies systematic recognition.

Some practitioners have dwelt much on the variations of external symptoms, from the circumstance of the membranes, or the substance of the brain, being in one case or another especially implicated; the membranous inflammation giving you marks of very high excitement, while the affection, falling upon the actual body or substance of the brain, presents features rather of a typhoid kind; and there appears some foundation for this alleged distinction, although, even in reference to this particular, we must not presume too largely upon our power of determining interior conditions by external signs.

Prognosis.—We may expect phrenitis to terminate favorably if the symptoms are soon mitigated by the treatment. The occurrence of any spontaneous discharge is a good indication; such as warm and free perspiration; natural and pretty copious diarrhœa; a considerable flow of urine, which shall soon throw down a considerable sediment; bleeding at the nose is also a good sign, when the powers are not much exhausted; a return of consciousness and tranquillity is of course a favorable symptom.

If the pulse continue hard and rapid, and the watchfulness and delirium do not subside, or if stupor succeed with dilated pupils, and subsultus tendinum occur, the prognosis will be unfavorable. Should the secretions and excretions continue to be small in quantity, or irregularly produced, and the fœces wanting in their proper color and consistence, we shall have to judge unfavorably. A total suppression of urine is a mark of much danger, and in this, as in some other disorders, is often a prelude to death.

Treatment.—In the management of very high and unequivocal affections of the brain of an inflammatory kind, it is often proper and necessary to draw blood very profusely; and the disorder will refuse to yield till you are successful in making a very considerable impression upon the system. In other cases, of a less marked and idiopathic character, the taking of ten or twelve ounces of blood will prove a better practice than that of ad deliquium depletion. If the practitioner be dexterous at these operations, the opening of the temporal artery, or the jugular vein, will often prove more advantageous than the common mode of taking blood from the arm; should this last be preferred, a large orifice ought to be made, and the quantity abstracted in a short space of time, especially in cases where we are desirous of producing faintness.

Elaterium, as a purgative, is often very useful in cerebral disorders, as it makes an impression on the system somewhat similar to large blood-lettings. In the course of the disease the saline purgatives, combined with diuretics, may be employed. See under *Fever*.

The foxglove is a favorite remedy with some practitioners in doses of from fifteen to twenty minims, several times in the course of the day. 'I have given,' says the late Dr. Currie, 'digitalis in inflammation of the heart, and the lungs, and the brain, and have succeeded with it in cases where I should otherwise have despaired.'

After the vessels have been freely depleted, and the inflammatory symptoms somewhat subdued, let the diaphoretics that are given partake a little more of the stimulant character.

℞ Liquoris ammoniæ acetatis f. ʒiij.
Ammoniæ subcarbonatis gr. vj.
Syrupi croci f. ʒij.
Aquæ puræ f. ℥iss.
Fiat haustus.

Take of liquor of acetated ammonia three fluid drachms, subcarbonate of ammonia six grains, syrup of saffron two fluid drachms, water a fluid ounce and a half. Mix into a draught.

Let ten or twelve leeches be applied to the head, and after venæsection let a large blister be put upon the nape of the neck, or to the legs. Let the head be kept rather high; if it can be done without producing much irritation, let the hair be all taken off with a razor, and to the naked scalp apply either cold iced water in bladders, or spirits and water, or an evaporating lotion composed of seven ounces of liquor of acetated ammonia and one ounce of sulphuric ether, or a drachm or two of muriate of ammonia with on ounce and a half of rectified spirit of wine ana six ounces and a half of water. Throughout the whole course of the complaint it will be found

of the utmost importance to keep the apartment in which the patient lies dark and cool, to forbid the intrusion of visitors, and to countermand all animal food excepting some broth, which may be sometimes serviceable, given under the collapse that has been produced by the necessary severity of the remedial processes.

In conclusion, says the author from whom we have extracted the last paragraph, I wish again to remark that phrenitis, or at least inflammatory disorder of the brain, will oftentimes present itself under less characters of decision; will be mixed up with other complaints; and will prove the gradual result of erroneous or obstructed action in other and distant parts. In these cases the treatment will require to be assiduously directed to these primary and constitutional conditions. On the other hand it is to be recollected that these supposed primary are not seldom actually secondary states, and that a bad condition of the encephalon will produce disordered viscera with as much or more readiness than disordered viscera will bring on brain affection.

In the treatment of delirium tremens opium is our sheet anchor; it is impossible to lay down any directions for its dose of undeviating application; but two or three grains of the powder of opium, combined with some liquor of acetated ammonia, are often necessary. The bowels must at the same time be attended to, and sometimes, previously to the administration of a full dose of opium, it may be proper to abstract some blood notwithstanding the prevailing debility. The compound powder of ipecacuan is a good form of administering opium in many brain affections where we are desirous of allaying irritation, but are fearful of opium by itself in substance or tincture. The vegetable acids too are useful adjuncts of opium, when we have to administer it in cerebral disorder. From six to ten grains of the citric acid dissolved in an ounce and a half of water, will form a good vehicle for small and repeated doses of tincture of opium, when these are required in phrenitic irritations.

347. *Cynanchial disorders.*—In the genus cynanche Dr. Cullen includes the cynanche tonsillaris, or inflammatory sore throat; the cynanche maligna, or malignant sore throat; the cynanche trachealis, or croup; cynanche pharyngea, or inflammation of the pharynx; and cynanche parotidea, or mumps; each of which demands separate consideration.

348. *Inflammatory sore throat* is an affection of the mucous membrane lining the fauces, and especially of the tonsil glands, sometimes extending down the pharynx, at others spreading about the lining membrane of the nose, and producing a suffocating sensation and difficult breathing; but the inflammation and swelling of the tonsils are the main characteristics of the disorder now under notice, and this inflammation is sometimes so high, and the consequent tumefaction so great, as to impede deglutition, and even materially to interfere with the respiratory process. When the inflammation takes its course towards the orifice of the eustachian tube a temporary deafness will be attendant upon quinsey. The fever which accompanies the local affection is either synochal or synochous, according to the constitutional condition of the patient and the extent of topical disorder. There is generally a teazing and irritating increase of saliva in these affections, which is more observable and troublesome on account of the difficulty of swallowing; the cheeks are often swollen, the eyes red, and the patient very irritable and distressed.

Causes.—Those of inflammation generally; and especially an exposure to sudden changes from heat to cold and from cold to heat. Its occurrence is principally late in the winter, or early in the spring; it is exceedingly liable to recur from a slight exciting cause, the system having once been affected by it.

Distinctions.—The inflammatory quinsey is distinguishable from the malignant sore throat by its being more of a phlegmonic than an erythematic inflammation, and by its tendency to full and complete suppuration rather than to the formation of small separate ulcers. The fever too is for the most part without those typhoid characters which denote the malignant species.

Prognosis.—The termination is usually favorable, and within a few days of its occurrence. There have been instances of suffocation being produced by the enlargement of the glands during the suppurative process; but this is an exceedingly rare event, nature for the most part effecting the discharge, or if not the lancet may be plunged into the suppurating tumor, and thus the threatened occurrence averted. When the prognosis is to be unfavorable the disorder passes into the erysipetalous and malignant kind.

Treatment.—If the patient be of a full plethoric habit, and the inflammatory excitement considerable, venæsection should be had recourse to; but for the most part we should say it is not requisite. A scarification of the tonsils often gives considerable relief. Emetics may be administered at the onset, composed of half a grain of tartrate of antimony, and two or three drachms of wine of ipecacuan. When leeches are employed, they are best placed two or three under the lobe of each ear. Saline diaphoretics and purgatives may be employed according to circumstances (see under *Fever*); blisters put to the back of the neck, not to the throat; and, the inflammation having been got a little under, the following gargle may be frequently used:—

℞ Acidi muriatici f. ʒß.
Syrupi papaveris f. ℥ij.
Infusi rosæ f. ℥vj.
Fiat gargarisma.

Take of muriatic acid half a fluid drachm, syrup of white poppy two fluid ounces, infusion of roses six fluid ounces. Mix for a gargle.

Emollient poultices, made of bread and milk or linseed meal, may be applied to the sides of the neck for the purpose of assisting the suppurative process; and the inhalation of warm water from Mudge's instrument (into which some tincture of opium is put—about an ounce of the tincture to half a pint of the water), may prove serviceable in allaying irritation.

Small doses of sulphate of quinin, or a draught or two in the day of decoction of bark, with ten or fifteen minims of the diluted sulphuric acid, may assist convalescence, especially when the

onsil affection, instead of entirely subsiding, falls into a sort of indolent state.

The second species of the cynanche, the cynanche maligna of Cullen, will fall to be considered under the head of scarlatina among the exanthemata.

349. *Croup*.—This disorder is characterised by a sonorous inspiration of a very peculiar kind; it comes on sometimes suddenly, and at other times is preceded by common catarrhal irritation, which lasts for days; when it is established the difficulty of breathing is very distressing. The attendant cough is usually hard and dry at first, but afterwards a viscid matter is secreted, and the efforts to expectorate it threaten suffocation. The disorder sometimes terminates life in less than eight-and-forty hours from the attack; at other times it runs on to the fourth or fifth day, and may then terminate fatally. Croup is a disorder of childhood, generally occurring before the third year, but sometimes it takes place when the child is nine or ten years old. It is apt to recur.

There seems some difficulty in accounting for the disorder being confined to childhood; but this is the fact; and it has been explained by some on the supposition of the mucous lining of the wind-pipe, which is the seat of the disorder, undergoing some change of susceptibility.

Death from croup is usually produced by the rapid formation of an adventitious membrane or tube of coagulable lymph, which in many cases extends down into the ramifications of the bronchiæ; there is at the same time often a muco-purulent secretion which assists to plug up the passage and impede the breathing, and the spasm which the violence of the inflammation brings upon the muscles about the glottis often contributes to the fatal termination.

Causes.—Croup is produced by the common excitants of inflammation in children predisposed to the disease, the predisposition consisting in a full habit with robust stamina, or in a particular susceptibility about the respiratory organs. Teething seems often to excite croup. A disordered state of the stomach and bowels may excite the disorder, and very generally predisposes to it. Some peculiarity in the atmosphere at times tends to induce it, for it occasionally proves endemic and epidemic. It has, as we have intimated above, a tendency to return by habit. In some cases it would seem to be contagious.

Distinctions.—Croup is distinguished from other disorders of the wind-pipe and lungs by the peculiar stridulous breathing; it has intermissions and exacerbations like spasmodic asthma, but the intervals are not so free from disorder as in the latter case, and the attendant irritation is more decidedly febrile.

Prognosis.—Croup is proverbially a dangerous disease. We may, however, expect a favorable termination when the expectoration shortly becomes free and relieves the little sufferer. When no expectoration takes place, and the voice increases in acuteness, without the irritative fever declining, we must expect an unfortunate termination.

Treatment.—Promptitude and decision are here necessary. If the practitioner be called in before the disease has fully established itself, an emetic of ipecacuan may be administered with the addition of some emetic tartar.

℞ Vini ipecacuanhæ ℥ß.
Antimonii tartariz. gr. i.
Aquæ puræ ℥ß.

Fiat mistura, sumat coch. min. subinde donec excitetur vomitio.

Take of ipecacuan wine half a fluid ounce, tartarized antimony a grain, water half a fluid ounce. Make them into a mixture, of which let the child take a tea-spoonful from time to time till vomiting is excited.

When the disease is fully established, the calomel treatment will be found the most efficacious, as this medicine possesses the power of breaking down the crasis of the blood, and thus preventing the formation of the adventitious membrane which, as we have above said, is formed of coagulable lymph.

℞ Hydrargyri submuriatis gr. ij.
Pulv. sacchari albi gr. iij.

Fiat pulvis, secundis horis sumendus.

Take of calomel two grains, white sugar powdered three grains. Make it into a powder, and administer it every two hours.

In cases of very high irritation, and much fulness, bleeding by leeches or opening the jugular vein may precede or accompany the calomel plan; but we must be careful not to carry the bleeding too far, lest we induce that spasmodic action which, as above intimated, tends to hasten suffocation.

Some practitioners are stated to be exceedingly successful in the employment of tartar emetic, so as to induce and keep up a constant nausea, till the force of the disease is broken.

An external application to the chest of the following ointment may be of much use by exciting vicarious irritation of the skin.

℞ Antimonii tartarizati ℈j.
Opii pp. pulv. ℈j.
Cerati cetacei ʒij.

Fiat ung. cujus applicetur thoraci pars sexta, viâ fricationis, sextâ quâque horâ.

Take of tartar emetic and opium of each a scruple, cetaceous ointment two drachms. Make an ointment, of which the sixth part is to be applied to the chest by friction every sixth hour.

Warm bathing may be used with advantage when the plethoric fulness and high action have been in some measure subdued by the bleeding, or calomel, or antimony.

Bronchotomy or laryngotomy has been proposed, and we have seen it had recourse to, but not with eventual success. The fact is, that the membrane of which we have spoken, for the most part, in fatal cases of croup extends down into the bronchiæ, and there is moreover such a loss of power locally and generally before the operation would be at all justifiable, that we cannot expect much from the expedient in question.

In all cases of croup, the probability of the inflammation recurring ought to be guarded against, and preventive measures had recourse to, such as an attention to the condition of the stomach and bowels, and care against repletion.

350. *Pharyngeal and laryngeal inflammation.*—There is a species of erythematic inflammation which occasionally affects the pharynx, which is attended with difficult deglutition, but not of impeded respiration, unless from the pharynx the inflammation extend itself into the larynx, and then the laryngitis of some authors comes to be formed, which is a disorder of much danger, and often proceeds with rapidity to a fatal termination.

This cynanche laryngea, or laryngitis, is attended with difficult respiration, with a sense of suffocation, and often a simultaneous difficulty of deglutition.

Distinctions.—Croup is different from an inflammation merely of the larynx in the circumstance of that stridulous or sonorous respiration, which we have above stated characterises the croupal inflammation; it occurs moreover in adult or advanced life, which is not the case with croup. From an actual affection of the lungs the laryngeal disorder is distinguished by a certain kind of hoarseness and impediment of respiration referred to the wind-pipe at its upper part. From asthma laryngitis is distinguished by its attendant fever, and by its being wanting in that complete intermission which characterises the latter ailment.

Causes.—Sudden alternations of heat and cold. Violent exercise of the voice. Irritations in the alimentary and intestinal canal, producing the disorder in a sympathetic way.

Prognosis.—Laryngeal inflammation is a disorder of much danger. It often appears very active and spreading, and unless checked shortly terminates existence. Sometimes suppuration is formed, a collection of matter is found in the sacculi laryngis, or an effusion of coagulable lymph terminates the disorder more in the way of croup.

Often a chronic inflammation establishes itself in the larynx, which is attended with a slow fever, that eventually takes on the hectic character, when the disorder from the state of mere inflammation shall have passed on to its ulcerative stage. Chronic laryngitis is also a disease of danger. This disorder, when it terminates fatally, is often confounded with phthisis, and in some cases a species of actual consumption is occasioned by the extension of the irritative action down into the lungs; but very often life is terminated by ulceration in the larynx without any accompanying disorder of the lungs.

Treatment.—When the larynx is affected with active inflammation, large bleedings are called for; after which, and it may be right to push the bleeding to the extent of producing fainting, blisters may be had recourse to; these, however, should not be applied immediately over the part affected, but upon the breast or neck. The ointment recommended under the head of croup, may likewise prove serviceable. Warm water from Mudge's inhaler may be employed with tincture of opium and ether: the latter is more especially proper when the disorder takes on somewhat of a spasmodic as well as inflammatory character. In the chronic laryngitis, calomel and opium in the quantities of half a grain of each, repeated three or four times a day, may be of service. Sarsaparilla decoction with Plummer's pill, the dose of the former being a quarter of a pint three times a day, of the latter five grains every night, may likewise be tried.

These laryngeal affections are often the consequences of syphilitic poison upon a scrofulous constitution.

351. *Mumps.*—Cynanche parotidea. After a slight febrile irritation a swelling occurs under the angle of the lower jaw, and extends upwards behind the ear, or forwards upon the submaxillary gland; the swelling increases gradually for three or four days, and then subsides. For the most part no treatment is demanded beyond a dose or two of some common aperient. Occasionally, however, the inflammation takes on a more decided and severe form, and terminates in suppuration. At other times delirium follows the retrocession of the swelling by a sort of metastasis to the brain; and now and then when the neck swelling disappears, the testes in the male and the breasts in the female become affected in the way of transference.

Causes.—Vicissitudes of temperature, or teething, or affections of the stomach and bowels, may be productive of mumps; but it seems for the most part either to be occasioned by a particular condition of the atmosphere, or communicated from one child to another in the way of a contagious disorder.

Treatment.—We have said above that it is for the most part scarcely necessary to interpose medicine, but, when the secondary or metastatic disorders of which we have spoken take place, these must be treated by antiphlogistic remedies, and local refrigerants or repellents, according to the measure of the new irritation. When there is much of swelling, without any very active inflammation, warm fomentations or emollient poultices will be required, together with the administration of purgatives.

Before we conclude the subject of mumps, it is right to say that the young practitioner must not expect to find every affection of the parotid and submaxillary glands marked by this regularity in respect of time, nor attended by these sequelæ. We frequently find disorders that may be entitled to the appellation of mumps, to assume very different appearances from those mentioned by systematic writers on these disorders.

352. *Pneumonic inflammation.*—Dr. Cullen divides this into peripneumony and pleurisy, the one a disorder of the substance and body of the lungs, the other of the investing membrane, the pleura.

The general symptoms of peripneumony, or inflammation of the lungs, are pain in some part of the thorax, or over the whole breast; this pain being rather obtuse; the pulse is quick and sometimes rather hard and wiry; a cough is present which increases the pain, and throughout the disorder the breathing is difficult. Expectoration is at first difficult and painful, but in the course of four or five days it becomes free and the breathing is much relieved; the pulse also becomes softer and less quick, and the symptoms of the disorder decline.

When the inflammation, instead of thus giving way, goes on to suppurate, rigors are felt, the

pulse becomes more bounding and does not decrease in frequency, the respiration also becomes more oppressed but not so painful, and the patient often cannot lie down excepting on one side, this side being that which is affected.

When pleurisy rather than peripneumony is the disorder, or when the pleura rather than the substance of the lungs is inflamed, the breathing is more tight and straitened as it were; if you ask the patient to breathe, he tells you he cannot without the effort giving him much pain; the pulse is harder, the attendant fever often higher, and from the first the pain is increased by turning from one side to the other.

In addition to pleuritic or peripneumonic inflammation, Dr. Cullen speaks of a bastard peripneumony, but which he scarcely admits as a distinct species. This affection, which is distinguished from the pleuritic inflammation and the inflammation of the substance of the lungs, is considered as implicating rather the mucous linings of the bronchiæ, and has been therefore described more recently under the title of *Bronchitis;* the symptoms of which are difficulty of breathing, with hoarseness and obstruction rather than painful or strictured feeling, the pyrexia not being so high as in the other kinds of pulmonic disorder; and the pulse, though quickened, being without the hardness or vibratory character of the pleuritic inflammation. Mucous expectoration is here also from the first considerable; indeed the condition is nothing more than catarrh, assuming a more than ordinary severity, and extending itself down more upon the mucous linings of the bronchial cells.

Another species of bastard peripneumony is constituted rather of a gorged or congested than positively inflammatory state of the pulmonary vessels, and is marked by suffocative rather than by painful breathing; the countenance too looks flushed, the lips are often bluish, and every thing denotes rather obstructed respiration than inflammatory excitement. Let the student, however, always be aware that these different degrees and localities and kinds of pulmonary affection run constantly into one another, so as to defy the precision of nosology, and let it be recollected that here, as in other cases, systematists are too apt to define and divide, and describe with a freedom beyond the warranty of truth.

There is, however, another particular which the student ought also to recollect, and which on the other hand is more in accordance with the principle of systematic division; it is that the pleura being a serous membrane, an inflammation of it shows different characteristics from an inflammation of the bronchial membrane which is a mucous tissue; a disordered state of the latter does not excite so much inflammatory commotion as one of the former, but it is for the most part of a more insidious cast, and proceeds to the suppurative termination more gradually and insensibly.

Causes of pneumonic inflammation.—Changes of temperature; violent exercise of the lungs, or of the body generally; suppressed or obstructed perspiration; a constipated state of bowel, which last is a very general circumstance of predisposition, and often an exciting cause of the complaint

Distinctions.—There is sometimes a difficulty in distinguishing between inflammation of the lungs and the liver; occasionally, indeed, both organs are engaged with the disease at the same time. The distinction, however, is to be taken from pressure upon the region of the liver not so manifestly increasing pain when the disease is pulmonary rather than hepatic; in pulmonary inflammation also there is the absence of that sallowness of countenance and oppression of spirits, which is so characteristic of disorder in the liver. In inflammation of the lungs, we have above observed, that expectoration after a few days becomes free, when the disorder is about to terminate favorably; this is not the case when the liver is the seat of the disorder. There is an absence too in pneumonia of the shoulder pain, which characterises, or at least often attends, inflammation of the liver. In pneumonia there is more or less cough from the first; but an inflammation of the liver may exist for some time without occasioning any cough, which is of course more sympathetic and incidental than direct and essential. One author has told us, and occasionally we have observed the same thing, that the blood which is drawn when the liver is inflamed has its buffed surface tinged with yellow, and that the serous part of the blood is also more of this color than in pulmonary inflammation; it must however be allowed that this condition of blood is not invariably characteristic of inflamed liver, and therefore it cannot be received as an absolutely pathognomic or diagnostic sign.

Pneumonia is distinguishable from muscular or spasmodic pain of the chest by the attendant pyrexia, by its being more decided and continued, and by the attendant cough and expectoration.

Prognosis.—Pulmonary inflammation may be expected to terminate favorably when mucous expectoration occurs freely within two or three days from the attack; and, if this expectorated matter is tinged with blood, no unfavorable inference should thence be drawn. Warm and general perspiration, a deposit of sediment in the urine, spontaneous discharges, as of blood, from the nostrils, or diarrhœa, are favorable circumstances.

The unfavorable indications are rigors, delirium, cold, and partial perspirations; a purple appearance of the countenance, or a collapse of feature with an increase in the difficulty of breathing, while the expectoration either ceases altogether, or instead of being thick mucus becomes purulent and vanishes.

Treatment.—Venæsection, and that, in individuals of a firm fibre and when the inflammation runs very high, to a considerable amount; from sixteen to twenty ounces may be taken, and repeated the following day or two in succession. But, if the inflammation is not so considerable, and the powers of the system not so great, smaller quantities of blood may be withdrawn, as from ten to twelve ounces, and after the irritation is in some measure quelled let a blister be applied over the chest. The bowels must be evacuated by saline purgatives, which may be preceded by a five grain pill of calomel, a medi-

cine especially called for, if there be reason to suspect hepatic as well as pulmonary affection, or if the bowels had been much constipated previously to the attack of the chest disorder. When the blood-vessels and the bowels have been thus evacuated let one grain of calomel and one of opium be given every sixth hour; or, in place of this, administer nauseating doses of tartarised antimony with opium or poppy, as in the following formula.

℞ Antimon. tartariz. gr. i.
Syrupi papav. f. ℥j.
Aquæ puræ f. ℥v.

Fiat mistura: sumat partem quartam quartis horis.

Take of tartarised antimony one grain, syrup of white poppy one fluid ounce, water five fluid ounces. Make them into a mixture, of which let a fourth part be taken every four hours.

Some practitioners are very fond of digitalis. We have already made a quotation from Dr. Currie, who says he has succeeded in some cases with digitalis in inflammation of the brain, the heart, and the lungs, in cases where he should otherwise have despaired.

℞ Tincturæ digitalis ♏ x.
Tincturæ hyoscyami ♏ xxv.
Liquoris ammoniæ acetatis f. ʒiij.
Syrupi simplicis f. ʒij.
Aquæ puræ f. ℥iß.

Fiat haustus: quartis horis sumendus.

Take of tincture of foxglove ten minims, of henbane twenty-five minims, of liquor of acetate of ammonia three fluid drachms, of simple syrup two fluid drachms, of water a fluid ounce and a half. Make into a draught, to be taken every four hours.

When the inflammatory action is evidently lessened, and a tendency is manifested towards expectoration, let expectorant medicines be combined with refrigerants, diaphoretics, and anodynes.

℞ Vini ipecacuanhæ ♏ xxv.
Syrupi papaveris f. ʒi.
Pulv. potassæ nitrat. ℈ß.
Syrupi tolutani f. ʒij.
Aquæ puræ f. ℥iß.

Fiat haustus.

Take of ipecacuan wine twenty-five minims, syrup of white poppy a fluid drachm, powdered nitre half a scruple, syrup of tolu two fluid drachms, water a fluid ounce and a half. Mix into a draught.

The class of medicines called expectorants are chiefly applicable when the affection has been principally on the bronchial membrane; and in equivocal or bastard peripneumony, when there is considerable tendency to sinking in the vital powers, the subcarbonate of ammonia may be administered in combination with expectorants.

℞ Ammoniæ subcarbonatis gr. vij.
Mucilag. acaciæ f. ʒiij.
Vini ipecacuanhæ, ♏ xv.
Tincturæ scillæ ♏ xij.
Syrupi papaveris f. ʒi.
Aquæ puræ f. ℥iß.

Fiat haustus.

Take of subcarbonate of ammonia seven grains, acacia mucilage three fluid drachms, ipecacuan wine fifteen minims, tincture of squills twelve minims, syrup of white poppy a fluid drachm, water a fluid ounce and a half. Make them into a draught.

Small doses of cascarilla may be usefully employed in convalescence, combined with expectorants. The cascarilla, indeed, possesses an expectorant as well as tonic quality.

℞ Oxymellis scillæ f. ʒj.
Syrupi papaveris f. ʒj.
Infusi cascarillæ f. ℥iß.

Fiat haustus.

Take of oxymel of squill and syrup of white poppy of each a fluid drachm, infusion of cascarilla a fluid ounce and a half. Make them into a draught.

The terminations of pulmonic inflammation are, into effusion, constituting one species of hydrothorax; into general suppuration, forming the empyema of authors; into partial and confined suppurations, especially where there have been tubercles; in this case what are called vomicæ are formed; or there may be a pouring out of a muco-purulent fluid, either into the cavities of the pleura, or into the cellular substance of the lungs; or the termination may be in a congested state of the pulmonary capillaries with an effusion of blood from them; or the layers of the pleura may either be made to adhere together, or the adhesion may be between the substance of the lungs on one side, or the sides of the chest on the other. Indeed pleuritic inflammation cannot exist for any length of time unsubdued without throwing out the coagulable lymph which occasions these adhesions, whence results that impediment to respiration and want of free play in the lungs which so commonly follow upon pleuritis, even when the disease has been considered to terminate favorably.

The symptoms of vomica and empyema are marked in the nosology. When matter is distinctly perceptible in the chest, tapping has been occasionally had recourse to; but, in the general way, both local and general disorders are too confirmed to admit of permanent or radical relief by this measure.

353. *Inflammation of the heart.* Carditis.—The peculiar symptoms of inflammation of the heart, or rather of the pericardium (for it is for the most part in this membrane that the affection is resident), are sharp pungent pains referred to the region of the heart, attended with a sinking suffocating sensation, and catches in the breathing which are very much increased by motion or exercise of any kind; there is also a particular jar in the pulse, with a violent beating often of the carotids, and the whole of the patient's feelings are much more distressing and oppressive than in merely pleuritic disorder: the countenance as well as symptoms bearing marks of a vital organ being affected.

If the violence of the disorder somewhat subsides, but the inflammation does not entirely give way, a chronic affection of the pericardium is induced, and palpitations, continued dyspnœa, disturbed dreams, vibrating pulse, difficulty in

making any exertion, particularly in ascending a hill, œdema of the extremities, and eventually dropsy, occur.

Very little need be added, in regard to the treatment, to what has been advanced under the general head of pneumonia, only that the measures must be prompt and decisive, and we must not be deterred from the use of the lancet by the sinking sensations of the patient, if we feel pretty well convinced by other symptoms that the heart is in a state of active inflammation.

When the disorder has either fallen into a chronic from an acute state, or has been from the first of a chronic kind, the treatment is of course required to be different. Very small doses of digitalis may be employed in conjunction with calomel and opium as in the following formula, and great care must be taken to keep down irritation by avoiding all inordinate excitement either of mind or body, by avoiding full or stimulating diet, and preserving the intestinal evacuations free.

℞ Opii pp pulv. gr. ß.
Pulv. digitalis gr. i.
Hydrarg. submuriat. gr. ¼.
Mucilag. acaciæ, q. s.
Fiat pil. nocte maneque vel ter in die sumenda.

Take of opium in powder half a grain, powder of foxglove one grain, calomel a quarter of a grain, mucilage enough to make into a pill—take one night and morning, or three times a day.

Ointment externally applied to the chest, as in the following formula, may be useful in these chronic affections of the heart.

℞ Antimonii tart.
Opii pp pulv. āā ʒß.
Cerat. cetacei ʒij.
Fiat Ung., pars sexta app. om. nocte thoraci.

Take of tartarised antimony, and powdered opium, of each half a drachm, cetaceous ointment two drachms. Make them into an ointment, of which apply a sixth part over the chest in the way of friction every night.

When treating on the subject of rheumatism we shall have to revert to inflammatory affections of the heart.

354. *Peritonæal inflammation.*—Under the head of visceral affection we shall have immediately to treat of peritonæal inflammation, for when a disorder is called inflammation of the bowels or of the liver, it is very often only the peritonæal investment of the viscus that is much affected; sometimes, however, a great portion of the peritonæal membrane becomes the subject of inflammation, bringing with it a corresponding pain and fever without the immediate indication of any other visceral disease. Than pure peritonitis there is indeed scarcely any affection more common or more important for the physician to recognise. Its treatment when it is of the active kind is the same as that of active inflammation generally; and when of a more passive, insidious, or chronic nature, small doses of calomel, opium, and foxglove, as in the formula above for chronic inflammations of the heart, may be administered. The great object of the practitioner, in peritonæal inflammation, will be to prevent effusion into the abdominal cavity, dropsy of the abdomen when the inflammation is of a more spreading or erythematic kind, and adhesive union of a preternatural kind when the inflammation is rather phlegmonic than erythematic.

355. *Inflammation of the stomach.* Gastritis.—This disorder is not of very frequent occurrence; when it does take place it is for the most part in the mucous coat of the organ, and has been induced by the habit of intoxication, or by taking some poisonous material into the stomach, or occasioned by a specific disorder, as of schirrus affecting this part.

The symptoms of gastric inflammation when it does occur in an active form are an acute pain and sense of heat in the region of the stomach, the organ not bearing the mildest ingesta; there is a remarkable depression of strength, extreme anxiety depicted in the features, and sometimes delirium.

Causes.—Acrid or indigestible substances received into the stomach, alternations of temperature, a large draught of cold water while the body is hot, suddenly repelled eruptions of the surface, and metastasis, especially of gout.

Distinctions.—The burning heat of the stomach and attendant fever distinguish the pain of gastritis from that of mere spasm; from enteritis the stomach inflammation is distinguished by the seat of the pain, and intolerance of any thing that is attempted to be administered by the stomach. Hiccough too occurs in gastritis more speedily than in enteritis.

Prognosis.—If, in the course of two or three days, the pain and sickness cease, while the pulse becomes more free and full, and diminishes in frequency, the urine depositing a sediment, and the bowels becoming spontaneously loose, a favorable termination may be looked for. The unfavorable symptoms are a continuance of disease for some days, the pulse not decreasing in frequency, and hiccough remaining in spite of the medicinal processes.

Treatment.—General blood-lettings, and the free application of leeches to the epigastric region; afterwards warm fomentation and a blister, the copious employment of mucilaginous diluents, such as linseed tea, good barley water, with acacia gum dissolved in it. Emollient anodyne clysters are likewise to be injected.

℞ Tincturæ opii f. ʒß
Mucilag. amyli.
Aquæ puræ āā f. ℥vj.
Fiat enema.

Take of tincture of opium half a fluid drachm, mucilage of starch and water of each six fluid ounces. Make them into an enema.

℞ Olei ricini f. ℥iij.
Decocti hordei f. ℥v.
Fiat enema.

Take of castor oil three fluid ounces, barley-water five fluid ounces. Mix for an enema.

A common saline draught may be administered with five or six drops of tincture of opium, or pills with a grain of calomel and a grain of opium.

That erythematic, and at the same time chronic inflammation, which is often produced by a long habit of intemperance, especially by the habitual

and inordinate employment of spirituous liquors, is for the most part best treated by very small doses of mercurials joined with vegetable narcotics; the pain and irritation of real schirrhus is also occasionally mitigated by these medicines.

℞ Pilulæ hydrarg.
Extract. hyoscyami
Extract. conii āā gr. ij.
Fiant pilulæ duæ, nocte maneque sumendæ.

Take of blue pill, extract of henbane, and extract of hemlock, of each two grains. Make them into two pills, to be taken night and morning, two at each dose.

Schirrosities of the stomach generally, it may be remarked, take place about the cardiac or the pyloric orifice; and when the former is the case the stomach pain is immediately excited by eating; when the latter, the pain is more felt an hour or two after the meal, or when the digested material is making its way through the pylorus into the duodenum.

356. *Inflammation of the bowels.* Enteritis.—This is as common a disease as the stomach inflammation is rare; it is marked by pain in the part affected, increased by pressure; by great prostration of power; by much restlessness; great anxiety of countenance; spontaneous nausea and vomiting; small, contracted, and frequent pulse; with obstinate costiveness For the most part the pain is referred to the point where the large intestines commence, it being here where the lodgment is, as it were, made in the cæcum, that the inflammation of enteritis usually commences.

Causes.—Costiveness, or neglected bowel, often proves the actually exciting cause of enteritis; at other times it merely predisposes the individual to be affected by other causes—such as atmospherical vicissitudes, exposure of the body to cold, getting wet in the feet, spasms and contractions in the bowels and hernia becoming strangulated.

Distinctions.—Enteritis is distinguishable from colic by the presence of pyrexia, and by the pain being increased upon pressure; from the pain of gall-stones passing, it is to be distinguished by the quickness of pulse (for very violent pain occasioned by the passage of biliary concretions will exist while the pulse shall be under 100 in the minute); from nephritis or inflammation of the kidney, or from a fit of gravel as it is called, enteritis is distinguished by its being generally higher up in the abdomen, by its being without any retraction of the testicle, by the obstinate costiveness, and great sensibility to pressure.

Prognosis.—If the costiveness soon yields, if the pain from being fixed and intense changes its seat and becomes more moderate; if the pulse changes from the small contracted feel that it had at first to more fullness and less frequency; if the restleness and anxiety abate; and if an equal, warm, and free perspiration, occur, we may hope for a favorable termination.

The unfavorable signs are sudden cessation of pain, with the prostration continuing, and the pulse increasing rather than diminishing in frequency; hiccups, cold extremities, clammy and partial perspirations, and a drummy tense condition of the abdomen.

Remarks.—Inflammation of the bowels varies greatly, both as to degree, kind, and locality. Sometimes the villous coat of the bowel will be affected with erythema, and a diarrhœa will be the consequence rather than costiveness (indeed, diarrhœa in a very great many cases acknowledges this condition of the bowels for its cause); at other times the inflammation will be confined to the peritonæal investment of the bowel, and then the external tenderness and pain upon pressure are greater, and the pyrexia is for the most part more considerable; the peritonæum being a serous membrane, and serous membrane inflammation, as stated under the head *Pulmonary Disorder*, being usually attended with higher symptomatic irritation than inflammations of mucous tissues. Sometimes the fine membranes interspersed among the muscular fibres will be rather the seat of the disease, and in this case there will be the tormina and twistings noticed in the definition.

Then, further, in respect of degree, there is the greatest variety; sometimes the practitioner will hardly be certain of absolute inflammation, while at other times the symptoms are so marked and unequivocal that he who runs may read.

The mode of termination will be found much regulated by the seat and sort of inflammation. Decidedly marked enteritis, unless checked, tends with frightful rapidity towards a fatal issue; while the more fixed but less violent disorder, eventually comes to produce small points of ulceration, and tabid wasting. In this as in all other cases, and as we have all along endeavoured to enforce, the student is rather to be directed in his pathology and practice by attentive observation and reflection for himself, than by the distinctions and divisions and niceties of nosology.

Treatment.—When we are sure that active inflammation is going on in the bowels, we can only expect to arrest it by prompt and large blood-letting; it is the practice of some, and in our opinion it is a very good practice, to give a considerable dose of opium (say three grains of the powder in the form of a pill), immediately upon blood having been withdrawn,—the objection that would occur against this practice is, that as costiveness is a prominent and formidable circumstance in enteritis, so it should seem fearful to administer a medicine, the general tendency of which is to occasion costiveness; but it must be recollected that the inflammation and consequent irritation are the most fearful features of the malady, and that while that inflammation is proceeding it will be but of small avail to procure evacuations; then again the very constipation is sometimes produced by those states which opium is calculated to relieve; viz. a constricted state of the intestinal fibres. An actual objection indeed lies against the administration of violent purgatives in the minds of some when the constipation is occasioned by an inflammatory condition of the parts, inasmuch as the action of catharsis is they say likely to increase the evil we are desirous to subdue. This last objection may, however, be felt with too much weight, and it is for the most part desirable to procure a free passage through the bowels, more especially when we suspect that the malady has been induced by retained fæces.

At any rate purgative enemata should be injected.

℞ Magnesiæ sulphat. ℥iss.
Ol. ricini f. ℥j.
Aquæ bullientis f. ℥x.
Fiat enema.

Take of Epsom salts one ounce and a half, castor oil one fluid ounce, boiling water ten fluid ounces. Make them into an enema.

The following form of purgative by the mouth is most likely to be retained.

℞ Hydrargyri submuriatis ℈j.
Extracti colocynth. comp. ʒj.
Fiant pilulæ xvj, quarum sumat æger duas secundâ quâque horâ donec soluta sit alvus.

Take of calomel a scruple, compound colocynth extract a drachm. Make them into sixteen pills, and let two be taken every second hour till the bowels are opened.

Apply leeches and warm fomentations to the bowels; rub the abdomen all over with castor oil; give pills after evacuations have been produced containing a grain of calomel and a grain of opium. Warm bath. The application to the rectum of three or four drops of croton oil made into a suppository with crumbs of bread will sometimes excite to a discharge of the bowels when enemata fail. In case of invincible sickness, with every mark of introsusception, from four to six ounces of running quicksilver may be poured into the stomach.

The above directions of course apply to the more formidable and virulent shapes of the disease. The less decided, more insidious, more chronic, more equivocal, or more specific inflammations demand a discriminating adaptation to varying circumstances; and here we again repeat that the young practitioner must not be disappointed if he finds in practice different features and circumstances from those delineated by the nosologist.

357. *Inflammation of the liver.* Hepatitis.—For the definition of this, as of other diseases, let the student turn to the nosology. In the case, indeed, of hepatitis, Cullen has almost stretched out his definition, particularly of the chronic kind, into a history.

The pain, it must be recollected, in liver affections, varies very much both in itself and in its sympathetic consequences, as one or other part of the liver may be affected; the state of the bowels is irregular; sometimes a diarrhœa will be produced by the increased secretion and undue acrimony of the bile; at other times the inflammation will arrest, or very nearly so, the secretion altogether; and then of course there are clay-colored fæces and sluggish bowels; a yellowish tinge in the eye is not at all uncommon in hepatitis; the urine is high colored, and the spirits are for the most part dull and oppressed; the pulse is sometimes intermittent in chronic hepatitis, stomach derangements become conspicuous, and there is often a tendency to œdematous swellings about the ancles.

Causes.—Those of inflammation generally, immoderate use of spirituous liquors, mental affections; which last are sometimes causes, and sometimes consequences, of liver disorder. Autumnal heats and colds give an acrimony to the bile; this cause is more especially conspicuous in some of the tropical situations where heat and moisture act in combination, or speedy alternation; indeed, heat seems to possess some specific influence upon the liver; and it has been remarked by Dr. Thomas, and quoted by Dr. Gregory, that the liver, in warm climates, seems to be the seat of disease nearly in the same proportion as the lungs are in Great Britain: liver affections are occasionally induced by the cessation of the menstrual flux, which, like mental affection, is sometimes source, and sometimes sequence; protracted, or ill treated intermittents, are the cause at times of hepatitis; sitting day after day in one position, so as to impede the free circulation through the liver, may come to produce an inflammatory or congestive affection of the organ; tight lacing of stays; sudden repulsion of cutaneous disorder, or of perspiration; constipated bowel; in a word, whatever disturbs or impedes the circulation through this important and complicated organ may produce a measure of hepatic inflammation.

Distinctions.—From pneumonic inflammation (see PNEUMONIA), from gastritis by the absence of that burning sensation which is occasioned in gastritis by any thing taken into the stomach; and by the strength not being so suddenly prostrated as in gastritis, and by the pulse not being so small or oppressed as in gastric and enteric inflammation. Gall-stones passing give rise to suspicion sometimes that the liver is inflamed; but the intensity of the pain does not produce that irritation of the pulse which is always the product of inflammatory derangement. On this distinction, it will be recollected, we have before remarked; and it is an important one for the young practitioner to keep in his recollection.

Prognosis.—Favorable when the pain and febrile symptoms subside; the complexion loses its sallowness, and spontaneous evacuations occur; when perspiration breaks out general and warm, when the urine throws down a sediment, or when local inflammation breaks out in any part of the body's surface.

Unfavorable when the pulse continues full and frequent, and rigors take place; the pain having somewhat remitted, and being followed by a feeling of fulness and throbbing; or in the more chronic, and in this country more common form, the organ becoming hard to the feel; the yellow tinge of the countenance continuing; and, at length, abdominal swelling and fluctuation presenting themselves.

Terminations.—Inflammation of the liver may end in suppuration, the pus pointing outwards, and being discharged externally; or it may make its way through the lungs; or may penetrate into the abdominal cavity; or may get into the ductus communis, and through this channel be discharged; or it may get into the intestinal canal, in consequence of adhesion taking place between the inflamed liver and contiguous bowel, and a communication being made in this direct manner. Schirrous hardness, with enlargement, is a very frequent consequence of inflammation in the liver; tubercles and tubera, of all forms and sizes, are found in its substance; extensive adhesions

take place with neighbouring viscera and parts; vesicular cysts and hydatids become developed; unnatural softness, with enlargement, sometimes takes place; calculous or ossified matter becomes impacted in its body; in fine, there is scarcely any modification of morbid structure that the liver does not occasionally display upon dissection; and that with such a capricious irregularity as often to defy any precision of inference from symptoms during life.

Treatment.—General and local blood-lettings are demanded according to the urgency of the symptoms. After evacuations of blood, blisters and cathartics, as in other inflammations, are called for. Mercurial cathartics are in general preferred in inflammation of the liver, even of the most active kind; there may be some reason, however, to suspect that this free and indiscriminate action of mercury may be grounded too much on the notion of specific action. We in general prefer the saline cathartics, and those which, acting more upon the bowels than the liver, divert the current of blood away from the vena portæ. After purging and bleeding, calomel and opium may be given, as in pleuritic and enteric inflammation. When suppuration manifests itself, and the matter appears to point externally, it should be encouraged by warm poultices and fomentations. Suppuration being fully established, bark, and a somewhat more generous diet, may take the place of the antiphlogistic and lowering measures.

When the disorder is of a more chronic and less active kind, which is for the most part the kind or form we meet with in this country, the treatment is to be of a more deobstruent character, such plans being instituted as in some measure emulge the biliary organ of its load, or excite it into new actions. Topical bleedings by leeches or cupping glasses, and even small general bleedings, will be found requisite even in these cases; and here we may administer, with much advantage, small doses of mercury, in conjunction with the vegetable narcotics; the former with a view to excite and absorb, the latter to abate irritation.

℞ Hydrargyri submuriatis gr. i.
Extract. conii.
Extract. hyoscyami āā grs. ij.
Fiat pil. nocte maneque sumenda.

Take of calomel one grain, extract of henbane and hemlock of each two grains. Make them into a pill to be taken night and morning.

Mercurial inunctions are occasionally of service, as in the following formula:—

℞ Unguenti hydrargyri fortioris ℈j.
Camphoræ grs. v.
Fiat unguentum; applicetur omni nocte vel alternis noctibus in regionem hepatis.

Take of the strong mercurial ointment a scruple, camphor five grains. Make them into an ointment, which may be rubbed upon the region of the liver every night or every other night.

Or the tartarised antimony ointment, a formula for which will be found under *Inflammation of the heart*, may be used every night.

The taraxacum will often be found a useful medicine in chronic affections of the liver; it may be given in combination with some saline aperient.

℞ Potassæ tart. ʒij.
Extract. taraxaci ℈j.
Tinct. rhei f.ʒj.
Aquæ menthæ s. f.℥iß.
Fiat haustus.

Take of soluble tartar two drachms, extract of dandelion one scruple, tincture of rhubarb one fluid drachm, mint-water a fluid ounce and a half. Mix for a draught.

It is often advantageous to administer those medicines which act upon the kidneys in a sort of vicarious manner.

℞ Juniperi baccarum ℥iv.
Aquæ bullientis Oj.
Fiat infusum.
℞ Liquoris hujus colatæ f.℥iß.
Extract taraxaci ℈j.
Spiritus ætheris nitrici f.ʒj
Fiat haustus, ter in die sumendus.

Take of juniper berries four ounces, boiling water a pint. Make an infusion; of which, when cold and strained, take a fluid ounce and a half, and mix it with a scruple of dandelion extract and a fluid drachm of nitric ether. Make them into a draught, which may be taken three times a day.

℞ Sodæ subcarbonatis exsic.
Saponis duri, āā ʒj.
Pulv. rhei ℈j.
Ol. juniperi ♏ xxv.
Mucilag. acaciæ q. s. Fiat massa, in pilulas xxx. dividenda; sumat tres nocte maneque.

Take dried subcarbonate of soda, and hard soap of each a drachm, powder of rhubarb a scruple, oil of juniper twenty-five minims, make them into a mass, which divide into thirty pills, three to be taken night and morning.

The dandelion may be administered in decoction ad libitum; as may also the infusion of juniper berries.

In chronic affections of the liver some practitioners are partial to nitric acid, which may be given according to the following formula:

℞ Acidi nitrici diluti ♏ x.
Syrupi simplicis f. ʒiij.
Aquæ puræ f. ℥iß.
Fiat haustus, ter in die sumendus

Take of diluted nitric acid ten minims, simple syrup three fluid drachms, water a fluid ounce and a half. Make them into a draught, which may be taken three times a day.

The internal and external employment of chlorine has been recommended in hepatic and bilious affections. In its external use the aqua regia bath is formed; the following account of which is extracted from Dr. Mason Good's Study of Medicine.

'The aqua regia should be compounded of three parts in measure of muriatic acid, and two of nitric acid; and, in preparing them for use, a pint of the combined acid is to be mixed with the same measure of water. This constitutes the diluted acid or diluted aqua regia. The acid bath is to consist of three ounces of this

diluted acid to every gallon of water. It should, however, be observed by those who are inclined to form this mixture extemporaneously at their own houses, that if either of the acids be poured immediately upon the other, a large volume of very offensive gas will be disengaged, on which account it will be better to pour them separately and slowly on their proper measure of water.

'If the acids be of adequate strength, the mixture subdiluted for bathing, will, to the taste, have the sourness of vinegar, and perhaps prick the skin slightly if very delicate, but not otherwise after it has been applied to the skin half an hour. But since these acids vary much in their degree of concentration, as distilled by different chemists, there will be some variation in their power. The strength of the bath, however, should not be much greater at any time than the proportion here laid down; for otherwise it may excite a troublesome rash, and give a yellow hue to the nails and skin on the feet, or whatever other part is exposed to its action. A narrow tub for a knee bath, just wide enough to hold the feet, and reach the knees, should contain three gallons of the prepared bath liquor, and consequently about nine ounces in measure of the diluted aqua regia. For a foot bath, half a gallon may be sufficient, and a common washhand basin may be employed as a vessel for the purpose. The feet should remain in the bath for twenty minutes or half an hour; and the legs, thighs, and abdomen be in the mean time frequently sponged with the same. In the winter the water may be used warm; but this is not necessary in the summer. The bath may be employed at first daily for a fortnight or three weeks, and afterwards every other day, or only twice a week.'

358. *Inflammation of the spleen.* Splenitis. —We have already said that visceral inflammation may be mere peritonitis, when the peritoneal covering of the viscus is the part implicated with the disorder. It has likewise been intimated that a sort of gorged condition of the blood-vessels exists in some cases of visceral disorder that may approach to, but yet be under the grade of actual inflammation. Of splenitis as a peritonæal affection, we need add nothing more in the present place; but a measure and kind of splenitic affection often exists when it is not perhaps immediately suspected. When we have stomach irritations and derangements with vomiting of blood, with pains about the left shoulder, and general uneasiness, we ought to be upon our guard against disordered conditions of the spleen passing unnoticed.

Causes.—Those of visceral derangements generally. Protracted intermittents were formerly considered proverbially prolific of splenic enlargements; these are not now so common as formerly, partly perhaps on account of the comparative infrequency of the intermittents, and partly because in the treatment of them we are more careful to act upon the secretions and excretions than was formerly the case; for although the spleen does not appear to be an organ of secretion (see PHYSIOLOGY), yet its condition is much regulated by the state of other viscera that are secretory.

Distinctions.—Splenitis is perhaps most usually confounded with hepatitis when the disorder is chronic, and not unequivocally marked. The distinction is to be taken from the seat of the pain and enlargement, and from the presence or absence of bilious derangement, though there may be some deception in this last particular, since these viscera are connected together, partly in function, and partly in structure, as far as a connexion of nerves and blood-vessels may be said to unite them. From kidney affection, disorders of the spleen are more easily distinguished, inasmuch as the latter do not interfere so much with the urinary secretion, are confined to the left side, and are higher in their position than the kidney, and do not produce any retraction of the testicle.

Prognosis.—Mere chronic derangement of the spleen may last for years, and eventually be got under by judicious management. Even active inflammation of the organ does not tend so rapidly to disastrous consequences as the same measure of inflammation in some of the other viscera, partly perhaps because it is not subservient to chylopoietic functions as a secretory organ, and partly probably from the power the spleen may possess of working its own cure by spontaneous evacuations from its large and numerous blood-vessels.

Treatment.—Active and membranous inflammation must be treated upon the same principles as inflammation of other viscera affected in the same way; the chronic affections, to which it is subject, are best counteracted by an attention to the state of the bowels, by a mild and unirritating diet, and by the administration of deobstruents. See for a formula of mercury and anodynes under *Gastritis.*

359. *Inflammation of the kidney.* Nephritis. —We scarcely need add any thing to the definition given of this disorder in the nosology; we may say that although costiveness is not a pathognomic or necessary symptom, the bowels are often constipated, and that then the violence of the complaint is increased. Vomiting is not invariably an accompaniment of kidney affection, but there is almost always nausea; and when this condition of the stomach is present, without any obvious cause, we ought always to ascertain whether the kidneys, or in the female the womb, may not be disordered.

Causes.—Calculary concretions, violent exertions, as of riding, with strains or blows upon the loins, exposure to colds and heats, fæcal collections in the large intestines, acrid diuretics, as turpentine and cantharides, and metastasis, particularly of gout.

Distinctions.—Nephritis is to be distinguished from lumbago by the more fixed and less extended character of the pain; by its being increased on pressure upon the kidney; by retraction of the testicle; by the alteration in the quantity and quality of the urine; by the direction of the pain towards the groin, and down the thigh; and by the sickness of stomach. From enteritis by the pain being more behind than in front; by its not being accompanied by the obstinate constipation characteristic of enteritis; and by the pulse not being so rapid, oppressed, and small.

From gastritis by the sickness not being accompanied with the burning sensation at the stomach, especially when any thing is received into it. From gall-stones, or spasms upon the gall-ducts, by the seat of the pain, the absence of yellowness of the skin; by the urinary changes; and by the quickness of the pulse.

Prognosis.—For the most part favorable; the signs of approaching resolution, or on the other hand, the tendency to suppuration are marked, as in other inflammations. It may here be remarked, that purulent formation and discharge of pus with the urine may be the consequence of nephritis, and that this may continue for years without producing any great emaciation, any hectic fever, and without indeed much derangement of the patient's health. This fact, which is in opposition to the consequence of abscess in the liver, or some of the other viscera, has been accounted for by the kidney being an organ, as it is called, of waste, rather than of supply; that is, that its secretion is immediately discharged, and does not, as the secretion from the liver, &c., go to the assistance of alimentation. Nephritis sometimes ends in a destruction of the kidney's substance, but seldom is what would be properly called gangrene a consequence of kidney affection.

Treatment.—The inflammation must be met by the ordinary means of bleeding and purging. The purgatives should, however, be of the bland and unirritating kind; and, when saline cathartics are used, it is better perhaps to join them with manna. Castor oil is a good purgative in nephritic affections, especially when there is reason to suspect a lodgment of fæces in the colon, for the castor oil acts especially upon the larger intestines, and, as an oleaginous material, is more suited also to kidney irritation. Emollient and anodyne clysters, as ordered in enteritis, may be employed, and, when the pain is considerable, a drachm of tincture of opium may be added to them. Warm fomentations are always desirable; and the abdomen and region of the kidney may be rubbed over with castor oil. Drinks of linseed tea, or acacia mucilage, or barley water, or decoction of mallows, seem to have the power of blunting the irritation of the kidney; and, when nephritic irritation is caused by the presence of the lithic acid gravel, magnesia should be given pretty freely, either mixed with the drinks just mentioned, or administered alone with common water.

360. *Inflammation of the bladder.* Cystitis.—This is frequently marked by the same general symptoms as the kidney inflammation, only that the pain is lower down and in front upon the pubic region, and when the mucous or internal lining of the bladder is the seat of the affection mucous and muco-purulent, and sanious discharges are mixed with the urine: very often indeed affections of the prostate gland or membrane lining the internal surface of the urethra accompany the bladder affection, when this last is more of the chronic kind, and is seated rather in the mucous tissue than in the external surface of the organ.

Causes.—Local irritation as from calculus, extension of prostatic and urethral disease, blows upon the pubic region, and other common causes of inflammation.

Distinction.—The locality and consequence of the irritation, in general, will mark an irritation or inflammation of the bladder. The sympathetic irritations being those, a good deal of nephritis denotes that some portion of the urinary organs is affected.

Prognosis.—Active or external inflammation generally terminates favorably, if the proper remedies are timely had recourse to; but the mucous membrane affections are often tedious and obstinate, complicating themselves with affection of neighbouring parts, and sometimes giving rise to formidable, protracted, and structural disorder.

Treatment.—Acute inflammation of the bladder calls for the same treatment as nephritis, with the application of leeches to the pubic region, and warm anodyne fomentations over the lower part of the abdomen.

In the chronic affection the treatment demands variation from varying circumstances; when the irritation is present small doses of calomel and opium, as half a grain of each, two or three times a day, may accompany the castor oil and other bland purgatives which it may be necessary to administer; and when mere passive and habitual discharges have established themselves, a combination of copaiba balsam with one or other, or a mixture of two or three of the vegetable narcotics, may be employed with advantage.

℞ Extract. hyoscyami,
Extract. conii ā ā ℈j.
Copaibæ ʒiij.
Mucilag. acaciæ f. ʒvj.
Gradatim misceantur in mortario sensim affundens
Aquæ puræ f. ℥v.

Fiat mistura. Dosis cochlearia duo bis terve in die.

Take of extract of henbane and of hemlock of each a scruple, copaiba three fluid drachms, mucilage of acacia six fluid drachms. Mix them gradually in a mortar, gradually pouring on them five fluid ounces of water. Make them into a mixture, the dose of which is two table-spoonsful two or three times a day. Soap and soda may be given in combination with the narcotics. Emollient and anodyne injections, as of starch and opium, may often be injected into the bladder with much benefit.

361. *Inflammation of the womb.* Hysteritis.—In this disorder the spirits are for the most part depressed, and the pulse while it is small, is not perhaps, in the general way, quite so frequent nor so contracted as in the same measure of inflammation attacking other parts.

Causes.—Besides those of inflammation in general, as alternations of temperature, &c., the womb is liable to become inflamed by an interruption in the menstrual discharge, or in the lochia after parturition; a constipation of the lower bowel is also, by contiguity and sympathy, apt to affect the womb, and become an excitant of inflammation when the predisposition is strong.

Distinction.—From cystytis by the pain being deeper seated, and by the absence of the urinary changes.

Prognosis.—Peritonæal inflammation affecting the womb is often a highly dangerous disease, especially after parturition, when the powers have been exhausted by the process of delivery, and so much weakness and irritation are combined as to embarrass the practitioner with regard to the demands and admissibility of the case. When the inflammation is in the substance or body of the uterus, a gangrenous termination sometimes takes place, indicated by remission of the pain, prostration of power, hiccough, &c. If the peritonæal investment of the uterus is the seat of the affection, the unfavorable symptoms will be rather those of abdominal fulness and tension, with the pulse increasing instead of diminishing in frequency, and the supervention of rigors.

Treatment.—Blood-letting with more or less freedom and frequency according to the urgency of the symptoms and strength or weakness of the patient. In puerperal inflammation some practitioners abandon altogether the use of the lancet, and give calomel and opium; or even turpentine; but this form of the disease will be best discussed in the article MIDWIFERY. The treatment generally, both for the more acute and the more chronic kind, may be considered as properly analogous with that of cystitis.

362. *Rheumatism.* Rheumatismus. — *Symptoms.*—After exposure to cold or damp, lassitude and shivering occur, which sensations are followed by heat and pain of one or other of the large joints extending itself along the muscles; this pain is often as fugacious as it is violent. It remits in one part, and seizes suddenly and with equal force another; sometimes the surface assumes a redness, and there is for the most part swelling and a sense of tension in the joint or joints affected. The sympathetic fever that is excited often runs exceedingly high, but there is an absence of that hardness, and sometimes even celerity of pulsation, which characterises other inflammatory disorders; the tongue is white, the urine is high-colored, and there is often profuse perspiration. It is not only from joint to joint that rheumatism shifts; there is often a metastasis to the heart constituting one of the most formidable and dangerous species of carditis, to the muscles of the breast, and even to the pleura, diaphragm, and stomach. The bowels are often costive.

The chronic form of the disease is not attended by so much perturbation, but pains are experienced in the head, shoulders, knees, loins, and other parts, sometimes more fixed and sometimes more fugacious, leaving a paralytic debility in the parts affected, or tending to the induction of contracted limbs and stiffened joints. In either case, whether the disorder be acute or chronic, there is a disposition to be suddenly translated from one part to another; and another leading character of the malady is, that it does not incline to suppuration. The chronic is sometimes a sequela of acute rheumatism, at other times it takes place without having been preceded by the acute form of the disorder. In many cases after the complaint shall have fastened upon some one part particularly, and there lasted for a length of time, there will be a wasting of the muscular substance, and a consequent lessening in the bulk of the part.

Causes and peculiarities.—Cold, causing obstructed perspiration, damp air, wearing damp linen, or lying in damp beds; in fine every modification of cold, or transition of temperature, more especially when humidity accompanies this transition, will produce rheumatism.

There is some difficulty in respect of what systematic writers call the proximate cause of rheumatism, inasmuch as it is inflammation not only of a particular locality (this locality seeming, for the most part, to be the fine membraneous expansion which lines the muscles, or the tendinous aponeurosis), but the kind as well as seat is different from common inflammation; and it is moreover difficult to form an idea of that disorder being properly inflammation which shall in a moment's time leave the spot where it was raging violently, and be transferred with all its force, and at once, to another seat. There is one peculiarity of rheumatic inflammation, viz. that it does not tend to suppuration: this, indeed, we have already intimated, nor does it produce exudation quite in the way of erythematic, or rather erysipelatous, inflammation; in a word, it is a disorder (though often mixed up with others and thus greatly modified) in its nature, and essence, and characteristics, peculiar. The general division of this disorder is into acute and chronic as we have stated above. Some pathologists however, have proposed a third division into that of paralytic rheumatism; and there does seem some foundation for this adjective designation; for without any kind of affection that would imply inflammatory excitement, even of a specific or peculiar kind, the limbs are affected occasionally with a sense of coldness, and of a powerless condition, from causes which in other persons produce rheumatism, and which in several of their symptoms manifest an alliance with the more positive or legitimate shape of the malady.

Distinctions.—From gout rheumatism is distinguished by its affecting principally the larger joints, while gout is more common among the smaller; by its being for the most part more traceable to external excitants; and by its not being preceded by stomach ailments. Some indeed have endeavoured to prove that rheumatism is essentially a sympathetic affection, dependent upon gastric conditions. Yet, although no one will deny, who has been atttentive to the phenomena of disease, that pains of nearly a similar character to rheumatism are often consequent upon internal conditions, and gastric irregularities, he must be indeed wedded to system who maintains that rheumatism never establishes itself in the body, but through the medium of stomach irritation. Rheumatism further differs from gout in its attacking earlier in life, in its being attended when acute with more of sympathetic fever; while from common phlegmonous inflammation it is different in showing no disposition to suppurate, in changing from one part to another, and often by the redness and swelling being in no measure proportionate to the pain and irritation.

Prognosis.—Acute rheumatism requires often to be met by vigorous measures in the onset; and occasionally considerable blood-lettings would seem imperiously demanded; it is a fact, however, that blood-letting does not get hold of rheumatism quite in the same satisfactory manner that it does of common inflammation; and it is for the most part better to make a strong impression on the system by other means than detractions of blood. A pretty considerable dose of elaterium will sometimes serve to strangle a rheumatism in its birth.

℞ Extracti elaterii gr. i.
Confectionis aromat. q. s.
Fiat pilula.

Take of elaterium extract one grain; make it into a pill with a sufficient quantity of aromatic confection.

Colchicum too is exceedingly efficacious in the early stages of rheumatism; it may be given in the form of wine or the ammoniated spirit, according to the formula of Dr. Williams introduced into the last edition of the pharmacopœia, or in powder to the extent of five or six grains.

Sudorifics with digitalis may be employed when there is much of pyrexial irritation.

℞ Tincturæ digitalis purp. ♏ x.
Syrup papav. f. ʒij.
Liquoris ammon. acet. f. ℥ß.
Aquæ puræ f. ℥j.

Take of tincture of foxglove ten minims, syrup of white poppy two fluid drachms, liquor of acetate of ammonia half a fluid ounce, water one fluid ounce. Mix into a draught.

Saline purgatives also may be administered. Compound powder of ipecacuan, with very small doses of calomel, will often prove beneficial given at night.

℞ Pulv. ipecac. comp. grs. xij.
Hydrarg. submur. gr. ¼.
Fiat pulvis, horâ somni sumendus.

Take of compound ipecacuan powder twelve grains, calomel a quarter of a grain. Make them into a powder to be given at bed-time.

Or smaller doses of this very useful powder may be administered three or four times in the course of the day in conjunction with the liq. amm. acet.

℞ Pulv. ipecacuan. comp. grs. vi.
Liq. ammon. acet. ℥ß.
Aquæ puræ ℥iß.
Fiat haustus.

Take of compound powder of ipecacuan six grains, liquor of acetate of ammonia half a fluid ounce, water a fluid ounce and a half. Mix for a draught.

Calomel and opium, a grain of each made into a pill, will often prove beneficial in cases of obstinate rheumatic affection, after the high or pyrexial inflammation shall have in some degree subsided.

When rheumatism requires external application, we must be careful not to be too free with repellent, or cold, or saturnine lotions, lest we produce metastasis to internal parts. When these do take place, especially when the new residence is the pleura or the pericardium, or the heart, we must freely and fearlessly have recourse to blood-letting, and then follow it up by calomel and opium, to the extent of inducing a degree of salivation. Many lives, especially in the instance of heart metastasis, might be saved by this practice, sufficiently early had recourse to, and the practitioner ought always to be upon the alert against their occurrence.

Many years since the practice of giving the Peruvian bark very early and freely in acute rheumatism pretty generally obtained; it was administered even in the most inflammatory kinds and stages and with much reputed success. This practice, however, is at present almost entirely discontinued, and the bark is confined either to rheumatic disorders which ab origine manifest an intermittent or chronic disposition, or administered during convalescence, from the acute and more continued form of the malady. In intermittent rheumatism, if so any disorder may be characterised, the sulphate of quinin made into pills with crumb of bread, and given in doses of two grains two or three times a day, will occasionally prove of considerable service.

When, notwithstanding the continuance of the pyrexial irritation, there shall seem a tendency to sinking in the vital powers, ammonia will be found of much advantage; which, indeed, will sometimes check the disposition to metastasis. It may be given by supersaturating the common liq. am. acet. as in the following draught.

℞ Liq. ammon. acet. f. ʒiij.
Ammoniæ subcarb. grs. vij.
Syrup. papav. f. ʒij.
Mist. camphoræ f. ℥j.
Fiat haustus.

Take of the liquor of acetated ammonia three fluid drachms, subcarbonate of ammonia seven grains, syrup of white poppy two fluid drachms, camphor mixture one fluid ounce. Mix for a draught.

Treatment of chronic rheumatism.—The stimulant, warm, and tonic medicinals, are in this stage and state of the disease more unequivocally admissible; they may be combined or alternated with medicines that are usually called alteratives; and now it is that small and often repeated doses of the same medicinals may be had recourse to, which had in acute rheumatism been administered more largely, and for a shorter period.

℞ Guaiac. resinæ ʒij.
Pilulæ hydrarg. ʒj.
Pulv. digitalis ℈j.
Opii pp. pulv. ℈ß.
Mucilag. acaciæ. q. s.
Fiat massa, in pilulas quadraginta et duas dividatur: dosis pilulæ tres nocte maneque.

Take of gum Guaiac two drachms, blue pill one drachm, powder of foxglove one scruple, opium in powder ten grains, acacia mucilage as much as will suffice to form a mass. Divide it into forty-two pills, of which three are to be taken night and morning.

℞ Terebinthinæ Chiæ ʒj.
Pulv. antimonialis ℈j.
Guaiac. resin. ʒß.
Misceantur in massam, cujus formentur pilulæ viginti et duæ. Sumat tres nocte maneque.

Take of Chio turpentine one drachm, antimo-

nal powder one scruple, Guaiacum half a drachm. Mix them into a mass, of which form two and twenty pills. Take three night and morning.

℞. Pilulæ hydrarg. submur. comp. grs. ivß.
Opii pp pulv. gr. ß.
Fiat pilula. Bis in die sumenda, et sumat æger eodem tempore.
Decoct. sarsæ comp. f. ℥iv.

Take of Plummer's pill four grains and a half, opium in powder half a grain. Make them into a pill, and let one be taken twice a day, the patient drinking at the same time four fluid ounces of compound decoction of sarsaparilla.

Compositions of the above kind may be varied almost ad infinitum according to circumstances; and it may be proper, after a trial for some time of one formula, to have recourse to another. In but too many cases the disease will be found to baffle our varied endeavours. Warm clothing will prove one of the best alteratives. The subject of chronic rheumatism should not be contented with wearing flannel next the skin, but he should likewise wear the wash or chamois leather, which will sometimes prove more efficacous than all the drugs in the materia medica. Bandaging rheumatic limbs with very tight rollers has, in the practice of some, proved greatly available; and beating or rubbing them daily (the former is the most efficacious), will occasionally prove signally beneficial. Acupuncture and shampooing, the first consisting of running into the skin the fine points of several very small needles together, the second pinching and kneading it, are recently revived practices in this country, and sometimes are attended with very considerably efficacy. Warm bathing is usually employed, and lately the vaporous sulphur baths have been much in vogue; but it is questionable whether these last do not owe their efficacy to the penetrating quality of the vapor rather than to the specific operation of the sulphur. Electricity, more especially the voltaic electricity, or galvanism, is occasionally employed with decided and extensive advantage in cases of paralysis, consequent upon chronic rheumatism.

363. *Gout.* Podagra.—What is called a fit of the gout seldom makes its visit till after the age of puberty, though to this rule there are occasional exceptions. It seizes the first joint or ball of the great toe, which, with violent and peculiar pain, becomes also red, and in some degreee swollen. This attack is for the most part in the night after the first sleep; it lasts sometimes, with little abatement, for twenty-four hours, and then becomes mitigated; it again, however, recurs after the intermission of a day or two, and thus continues to harrass the sufferer from ten to twenty or thirty days, more or less; for even in what is called regular gout there is much irregularity in point of time. The gouty individual, having thus had his first fit, sometimes enjoys a respite for a few years, and in the first attack the locality is for the most part that just mentioned; but after three or four regular fits the feet, the hands, wrists, and other joints are affected, and the paroxysms come to visit more frequently, viz. annually, or twice or thrice in the year. Of the varying modes and aspects of gout the reader will find a good account in the appendage to the definition; but he must expect to find, in practice, even still more irregularity than is there set down. The atonic or misplaced form of the disorder especially falls upon the stomach, producing dyspeptic symptoms; upon the lungs, giving rise to asthmatic conditions; upon the heart, occasioning syncope; and upon the head, leading to vertiginous disorder; and upon the hœmorrhoidal vessels, giving occasion to piles The kidneys also are very commonly affected in this vicarious way in gouty subjects, to such an extent, indeed, that some have thought gravel and gout to be merely different expressions of the same malady.

Causes.—Gouty predisposition is constituted by a peculiarity of temperament; there is often fulness of vessels and an apoplectic make. It is hereditary; the natural tendency being increased by very high living, and by all those habits of indulgence to which the gouty are often constitutionally inclined. These indulgencies sometimes prove actual excitants of the disorder; and at other times the paroxysms are brought on by precipitately changing from voluptuous to abstemious modes of life; by exposure to cold at the time the predisposition is high; by the cessation of accustomed employment. It is always a fearful thing for a gouty merchant or tradesman to retire from the bustling anxiety of a city existence to the solitude and good living of country retirement; by inordinate evacuations; by mental anxiety, as well as mental ennui; in a word whatever tends to general derangement will be likely, in the disposed to gout, to bring on the fit. There seems in gout to be a predisposition to the secretion of lithic acid, with an accompanying alkali in small quantities; but whether the constitution which produces gout merely gives power to withdraw this secretion from the blood with more than ordinary readiness, or whether there is actually more of the material existing in the blood, does not seem to be satisfactorily ascertained. Certain it is that the same degree of digestive and general derangement happening in subjects not goutily disposed will not occasion gout, so that it is in one sense improper to look upon the affection as a mere stomach complaint.

Distinctions.—From rheumatism gout is distinguishable by the latter being as it were more constitutional, and having more obviously to do with deranged viscera; by the frequent presence of calculous disorder, and chalk stones as they are called, in the small joints, and by the metastatic or translated affection being often of a spasmodic or tonic kind, while in rheumatism it is more inflammatory. The perspirations in gout have also for the most part more acidity than in rheumatism, and gouty subjects are for the most part salacious, a constitutional bias which does not seem to have any thing to do in the way of connexion with rheumatism. For other marks of distinction see under the head of *Rheumatism.*

Prognosis.—Gout is not in general a disease in itself of danger, indeed the general feeling among pathologists and practitioners is that it rather preserves the constitution from formidable

advents of other maladies. This principle has, however, been combated by Heberden, Beddoes, and others Certain it is that, when a person dies of gout, it is rather of the consequences of the malady than of the malady itself; and the fatal termination seems in some measure connected with a want of power to produce a full paroxysm of inflammation; the humoral pathologists would say, a want of power to throw off the gouty matter which thus falls on the interior and occasions death. Apoplexy is exceedingly frequent in gouty habits; and formidable and even fatal affections of the stomach and heart, so as to cause death, do not seldom occur as a consequence of the gouty diathesis being very strong. The presence of chalk stones proves an inveterate diathesis, and often argues a fatal tendency.

Treatment.—When the local disorder is very considerable, it may be moderated by topical blood-letting, that is by the application of leeches, and refrigerant lotions; but the repression of the topical inflammation ought not to be effected precipitately, especially when the subject is advanced in age and his constitution has been debilitated by protracted disease. When the inflammation is not particularly high, but the pain still considerable, relief is sometimes obtained by the application of a camphor poultice, about a drachm or two of camphor being mixed with crumb of bread, and made into the consistence of a poultice with warm water. Warm and anodyne fomentations may also be employed. Some suppose, and with probably good reason, that beyond keeping the bowels attended to, and obviating as much as possible derangements in the digestive organs, the art of medicine is not capable of rendering any effectual or safe assistance; since shortening a paroxysm by the interposition of drugs or other remedial measures is calculated to hasten its return and eventually to increase and protract the disorder. It is certain that some medicines possess the power of lessening for a time the violence of gouty action. Elaterium as in rheumatism will do this. See *Rheumatism*. The colchicum too seems still more adapted to gout than it is to rheumatism, and the celebrated specifics seem principally to be made up of this last medicinal. Opiates combined with antimonials or calomel may be occasionally used; and the formula which will be found under the head of *Chronic rheumatism*, consisting of compound powder of ipecacuan and calomel, may occasionally be taken with considerable benefit. In all cases the bowels should be kept in action, and the warm resinous cathartics are rather indicated in old cases than the saline refrigerants. A combination also of the alkaline principle with the purgative is often requisite.

℞ Sodæ subcarb. exsic. ʒß.
Extracti colocynth. comp. ʒiß.
Mucilag. acaciæ q. s.

Fiat massa in pilulas xxiv. distribuenda. Sumat tres pro dose.

Take of subcarbonate of soda dried half a drachm, compound extract of bitter apple a drachm and a half, and of acacia mucilage a sufficient quantity. Make into a mass, and divide it into twenty-four pills. Three for a dose.

℞ Tinct. rhei f. ℥ß.
Liquoris potassæ subcarb. f. ʒß.
Infusi rhei f. ℥i.

Fiat haustus.

Take of tincture of rhubarb a fluid half ounce, liquor of subcarbonate of potass a fluid half drachm, infusion of rhubarb a fluid ounce. Make a draught.

Sudorifics may be occasionally employed; but we must not be very free in the employment of antimony when the powers of the system are rather low.

Fits of atonic or retrocident gout are best treated by volatile alkali, which medicine serves the combined purposes of an antacid and excitant, and sudorific.

℞ Ammoniæ subcarbonatis ℈ß.
Confect. aromat. ℈i.
Aquæ puræ f. ℥iß.

Fiat haustus.

Take of subcarbonate of ammonia ten grains, aromatic confection a scruple, water a fluid ounce and a half. Make them into a draught.

Or if there be much inflammatory condition, while atony is at the same time conspicuous, the liquor ammon. acet. may be supersaturated with five or six grains of the subcarbonate of ammonia, and in order to increase the secretion of urine a fluid drachm of the nitric ether may be added to the draught. When the stomach is attacked with gout, large quantities of stimuli are required, and ammonia with aromatic confection is the best form of administering them, but brandy or warm wine may be employed in the absence of more positive medicinals. Sulphuric ether, and ginger, are also useful in atonic and retrocedent gout.

The returns of gouty paroxysms are best prevented by an abstemious mode of diet, or rather by regular habits of living; by keeping the bowels acted upon, and preserving the urinary and cutaneous discharges free, regular exercise must also be taken. The aperients that are used should have reference to the prevailing acidity and the tendency towards obstruction or wrong action in the kidneys.

℞ Pulv. rhei ʒi.
Liq. potassæ subcarb. q. s.

Fiat massa in pilulas xvi. distribuenda. Sumat tres nocte maneque.

Take of powder of rhubarb a drachm, liquor of subcarbonate of potass as much as is sufficient to form a mass, which divide into sixteen pills, and administer three night and morning.

℞ Sodæ subcarbonatis exsic. ʒi.
Saponis duri ʒi.
Pulv. rhei rad. ʒß.
Aquæ q. s.

Fiat massa in pilulas xxxv. divide; et sumantur tres vel quatuor omni nocte.

Take of dried subcarbonaté of soda and venetian soap of each a drachm, powder of rhubarb half a drachm, water as much as is sufficient to form a mass; let it be divided into thirty-five pills, and give three or four every night.

Magnesia is a good aperient in gouty habits.

on account of its antacid and lithonthriptic qualities.

℞ Magnesiæ subcarb. ℈ij.
Spiritus ammoniæ aromat. f. ʒj.
Tinct. rhei f. ʒij.
Aquæ puræ f. ℥iß.
Fiat haustus.

Take of common magnesia two scruples, aromatic spirit of ammonia a fluid drachm, tincture of rhubarb two fluid drachms, water a fluid ounce and a half. Make them into a draught.

The continued use of bitters in gouty atony is a practice of questionable propriety; they have been supposed to give a tendency to apoplexy and paralysis, by curing or keeping under the gout, and thus fostering the tendency to these vicarious disorders. This may or may not be a correct notion; but, at any rate, the habitual employment of medicinals is an evil; and those medicines are more objectionable that do not act upon the secretions, as upon the skin, the kidneys, the liver, or the intestinal canal. We would not advocate the practice of giving for a constancy even purgatives, and diuretics, and diaphoretics, but they are, perhaps, less objectionable than the permanent employment of tonics and stomachics. Were it only that these last medicines excite to larger meals than the stomach is in a fit state to digest; this, in itself, would form an objection to them, and perhaps after all this is the principle upon which their protracted administration is objectionable as medicines against gout.

The Portland powder, which was formerly a fashionable anti-arthritic, is composed of equal parts of the roots of gentian and round birthwort, of the leaves of germander and ground pine, and of the tops of the lesser centaury, all dried.

Bath waters are useful in old gouty cases, but they have no specific agency. Indeed Heberden, who may be considered as high authority in gout on account of his practice being principally among the higher classes of the community, is altogether sceptical as to any good effected by them.

The student will observe in the nosology odontalgia (tooth-ache) and arthropuosis (joint disease) marked as genera of the order phlegmasia; but the consideration of these, beyond their being merely rheumatic affections, we refer to the article SURGERY. The remedies, however, noticed under the head of chronic rheumatism, will often beneficially apply to those affections of the joints which Dr. Cullen would designate by the term arthropuosis.

364. Order 3. RASHES ATTENDED WITH INFLAMMATION OR FEVER. Exanthemata.—Under this head we are to include, according to the nosological arrangement we follow, small pox, chicken pox, measles, scarlet fever, plague, St. Anthony's fire, the miliary eruption, vesicular eruption (pemphigus), and thrush.

For general remarks, on the principles of febrile eruption, we refer to the preliminary discourse attached to the present article.

365. *Small pox*. Variola.—The fever which precedes the eruption of the small pox is attended by pains in the loins and back, as well as pain in the epigastrium, noticed in the definition; there is often considerable drowsiness; and it is by no means uncommon for epileptic fits to make their appearance before the breaking out of the eruption. The first appearance of variolous eruption is like the bites of fleas; they usually come out first on the face, neck, and breast, and successively extend over the whole body. About the fifth or sixth day a small vesicle with a depression in the centre, and containing a fluid nearly colorless, is observable on the top of each pimple. Now some degree of swelling in the throat, and difficult deglutition come on, which, on the eighth day, has extended to the face and eye-lids, and at this period the pustules are fully formed. On the eleventh day the swelling of the face subsides, the matter in the pustule has changed to an opaque yellow, and the hands and feet begin to swell. There is now, too, an appearance of what is called secondary fever, which gradually subsides, and disappears on or before the seventh day.

When the small pox is what is called in the nosology confluent, a more violent fever precedes the eruption, while the rash itself breaks out in a more hurried and irregular manner. The eruptions assume an erythematic character, running into each other, and do not suppurate kindly, but contain an ichorous brownish matter; the swelling of the face, and the salivary discharge commence earlier, typhoid symptoms make their appearance, and often petechiæ are observed on the skin; blood is also discharged, by stool, and sometimes even by the urine; the bronchial cavities seem to be laden with irritation, and the little patient often dies suffocated.

Causes.—Specific contagion. This may be received either by the lungs or the skin; but in the latter case it is necessary that puncture or abrasion be used. Although the virus of small pox is exceedingly subtile, it does not appear to have the power of penetrating the scarf-skin, and thus making its way into the blood-vessels or absorbents.

Prognosis.—Now that the proper principles of treatment in small pox have come to be understood and acted upon, the prognosis may in general be considered favorable. In the confluent kind, however, there is always much to fear, on account of the typhoid tendency of the accompanying fever. The unfavorable indications are the flattening of the pustules, or disappearance of the eruptions, with a subsidence of the swelling of the face; the breathing becoming much oppressed or obstructed, and marks of inflammatory and congestive conditions about the head or the liver.

Distinctions.—A common attack of febrile disease is usually distinguishable from the fever preceding small pox, by the latter being attended by pain in the loins and tenderness in the epigastrium; and there is in general more of drowsiness in the fever preceding small pox eruption. When the eruptions break out they are distinguished from measles by being larger, fewer, more distinct, and more papular; from the chicken pox, by their being more distinct and

circumscribed, as well as more uniform in size; and, by a more regular and gradual progress of preliminary fever, and eventual suppuration. The pustule too is cellular and depressed in the centre, if it be genuine small pox.

Treatment.—It is merely necessary, in common small pox of the distinct kind, to enjoin a cool regimen; and if the fever runs high to administer saline and aperient medicines, as in common fever. If there is much restlessness, the addition of a little syrup of poppy, as in the following draught, will be found useful:—

℞ Liquoris ammon. acet. f. ℥ß.
Syrup. papav. f. ʒij
Sp. ætheris nitric. f. ʒj.
Aquæ puræ f. ℥i.
Fiat haustus.

Take of liquor of acetate of ammonia half a fluid ounce, syrup of white poppy two fluid drachms, spirit of nitric ether one fluid drachm, water a fluid ounce. Make them into a draught.

In the confluent small pox, the treatment is rather that demanded in typhoid fever. A combination of nitre and cinchona bark will often be found useful; and it will be expedient to preserve the bowels free. In tendencies to sinking, especially if the eruption appears to recede, or manifest an inward direction upon the mucous lining of the bronchiæ, the subcarbonate of ammonia must be given, and blisters applied to the chest. If diarrhœa be urgent, administer opium with ammonia; and in some cases a combination of calomel and opium in equal doses, say from a quarter of a grain to a grain of each, according to the age and circumstances of the patient, will be desirable. Here it is allowed that the mucous surfaces are in a state of erythematic irritation, but it is that kind and degree of inflammation which will often best yield to bark, wine, opium, and cordials; or, at least, those must at all events be given when the system is sinking. Even in more distinct small pox, when the pock becomes flattened, and manifests an indisposition to come freely out, ammonia may be administered with signal advantage; should there be much febrile action at the same time, it will be right to supersaturate the saline draught with the subcarbonate of ammonia.

[*Note*—In the above account we have treated of the distinct and confluent small pox, as if they were different kinds of disease; it should, however, be remarked, that the kind rather refers to the state of the individual and to epidemic constitutions in the air, than to any abstract or essential difference in the virus itself; the most confluent will produce in another the most distinct, and vice versâ.]

It might be expected that we should in this place enter upon a disquisition upon the substitute for small pox—the vaccine matter, but we purpose to devote a separate article to this important topic; and, under the word Vaccination, the reader will find a full estimate of the comparative merits of the small pox and vaccine inoculation.

366. *Chicken pox*, varicella.—The definition is a sufficient history.

Distinction.—We have already stated the principal points of distinction between this eruption and that of small pox. It is generally about the fifth day at furthest that the eruption disappears; and, unlike the small pox, it often commences about the hip and back.

The *prognosis* is always favorable; and the *treatment* necessarily simple. Indeed medicine is scarcely at all required; or, at furthest, some gentle aperient to keep down the little irritation that may be induced.

It has been contended by some, more especially by Dr. Thomson of Edinburgh, that small pox, the vaccine virus, and the varicella, or chicken pox, are mere degrees and modifications of the same poison. Others have advocated their essential distinction. On this head we shall have further to remark when treating of cow-pox under the word Vaccination.

367. *Measles.* Rubeola. Morbilli.—The prominent symptoms of this disease are exceedingly well pointed out in the nosological definition. The eruption usually appears first about the face and neck, and successively spreads to other parts of the body. The fever does not, as in small pox, abate upon the appearance of the eruption, but rather increases as do the catarrhal symptoms. Sometimes the eruption at first appears to come out full and free, but very soon disappears, and oppression of the præcordia, difficulty of breathing, and other internal symptoms present themselves. At other times, during the whole course of the disease, the skin shall be but just sufficiently marked to prove the existence of the complaint, and scarcely that. On the very day that we are writing these remarks, we have seen a child who is evidently laboring under the influence of measles' virus, but whose disorder would scarcely even be suspected measly, were it not that other children of the same family are simultaneously, and these obviously affected.

Causes.—Contagion as in small-pox. It is curious that small-pox and measles were treated of in the first instance as one and the same disorder; and, as the identity of vaccine virus with varicella and variola has been imagined, so has it been further supposed by some that measles and small-pox poison have only become essentially different by the operation of time and circumstance.

Distinction.—From small-pox in the first breaking out by the presence of catarrhal symptoms, and by the more clustered and less papular appearance of the eruption. Measles constitute a sort of midway eruption between the more distinct papula of the small-pox, and the more erythematic and rashy character of scarlatina; from this last measles are also distinguishable by the coryza and sneezing as opposed to the cynanchial irritation of scarlet fever.

Prognosis.—It is rather fearful to give a favorable prognosis of measles from their first appearance, and for the first few days we should always leave it open to contingencies; for sometimes the skin affection will appear to come out free and favorably, and then will suddenly, and without apparent cause recede, and internal damagement will take its place. If the fever run high; if the difficulty of breathing be considerable; if delirium take place, if the eruption display an internal tendency, if it assume a pallid appearance,

especially if it become livid; and petechial spots are intermixed with it; considerable danger is to be apprehended. Much diarrhœa and vomiting are bad symptoms; but slight diarrhœa with a free skin and easy expectoration are favorable signs. It is always well to see a good and regular crop of eruptions.

Treatment. The indications are to keep down excitement; to guard against or combat local inflammation, especially inflammation of the lungs; and to excite and stimulate when the powers of the system seem to be sinking.

Excitement is to be moderated by an equal temperature, carefully preventing sudden or partial applications either of heat or cold; for, although it is not expedient to pursue the heating and alexipharmic plans of former times, we cannot on the other hand adopt the cooling practice quite so freely and fearlessly as in the small-pox, on account of the tendency of the eruption to recede upon the internal membranes, and on account of the catarrhal irritation that is always in a greater or less degree present. Saline purgatives are to be given as in common fever, according to the measure of the pyrexial irritation; general blood-letting may be had recourse to if the patient be an adult, and the phlogistic diathesis runs high, but for the most part this is not necessary. Leeches must be applied to the chest if the pulmonary symptoms become urgent, or to the head should delirious and phrenetic irritation manifest themselves. Digitalis is for the most part a useful medicine in measles, and it may be joined with nitre and poppy syrup, as in the following formula.

℞ Tincturæ digitalis purp. ♏ x.
Syrup. papaveris f. ʒiß
Pulv. potassæ nitrat. ℈ß.
Misturæ amygdalæ f. ℥iß.
Fiat haustus.

Take of tincture of digitalis ten minims, syrup of white poppy a fluid drachm and a half, nitre ten grains, almond emulsion a fluid ounce and a half. Make them into a draught.

When the internal tendency of the eruption, as above alluded to, becomes combined with much debility and sinking, the subcarbonate of ammonia will prove one of the best medicinals, since it has a sudorific as well as a stimulant quality (see under *Confluent small-pox*; the same indications being present, and the same rules applicable).

The cough which follows measles ought to be carefully attended to, and moderated by attention to diet—by the administration of digitalis, or hyoscyamus, or conium, or poppy, or a combination of some or all of them; and the child be removed to a mild air. If the pulmonary irritation become considerable and protracted, a blister may be laid on the chest, or the tartrate of antimony ointment applied; for if these indications of remaining disorder be not got under, they are apt, in their continuance to lay the foundation for future phthisis.

368. *Scarlet fever.* Scarlatina.—There is some uncertainty in respect to the time at which scarlet fever first made its appearance. It has been supposed by some to be a modification of some of the other eruptive diseases, but there seems a good deal of difficulty attending the investigation respecting the precise point of time, and the particular part of the world, in which this and some of the other acute affections of the exanthematous kind first appeared in a distinct and decided form. 'It has been suspected that the contagion came originally from Africa. Be this as it may, it first broke out in a severe form in Spain in 1610, from whence it spread to Naples where it raged epidemically in 1618. In 1689 the same disease made its appearance in London, and was described by Dr. Morton, though not with the accuracy of the first Spanish and Italian authors. In 1735 it broke out in North America and spread gradually but slowly over that continent. One of the most curious circumstances in the history of the disease is the slowness of its diffusion.'

Symptoms.—The definition comprehends almost all the common symptoms of the complaint. The inflammation of the skin appears as an erythema, and is not phlegmonous, nor papular; the accompanying fever showing often a typhoid tendency, especially when the tonsils are much ulcera'ed. The face is often sensibly swelled about the third day. Scarlet fever, like the measles, is various in respect to the freedom with which the cutaneous affection appears; sometimes we have a promise of a large crop, or rather of a universal redness, which in a few hours recedes, and becomes pale; sometimes the throat is malignantly affected; at other times there is scarcely any tonsil disorder. The sequelæ, too, of the fever are very irregular, health and strength gradually, at times, following upon the cessation of the complaint in its active form; while at other times, after a day or two of good promise, languor and weakness are felt, the urine becomes scanty, and dropsical tumefactions make their appearance. For the most part, these are confined to the skin; but now and then, especially if there have been much pulmonary or abdominal affection during the fever, symptoms become manifest of hydrothorax or ascites.

Causes.—Contagion of a specific nature, communicated it should seem as other contagions by the respiratory organs, the outer skin forming a complete barrier to its entrance into the system; the power of infecting is said to continue certainly a fortnight from the time of the eruption.

Distinction.—From measles (see *Measles*). From small-pox (see *Small-pox*). The distinction proposed between malignant sore throat and scarlatina cynanchica does not perhaps exist; for, although a malignant ulcer in the throat may be occasioned without the specific poison of scarlet fever being applied, we often see several children of a family affected simultaneously, one having the sore throat without having the skin disorder, another having the eruptive without the cynanchial complaint. Indeed, it is now pretty generally supposed that scarlatina and cynanche maligna are produced by the same specific contagion.

Prognosis.—For the most part, upon the whole, more favorable than measles, since the internal tendency upon vital organs is not so great. The later and less hurried the eruption, after the first

appearance of fever, the better; and the fever assuming less of the typhoid type is favorable. The unfavorable symptoms are delirium; coma; præcordial anxiety; hurried respiration, with a thick voice and difficult deglutition; partial patchy eruption, instead of a full and universal floridness of skin; pains about the angle of the jaws, and ears, with acrid running from the nasal membrane or meatus auditorius; saliva tinged with blood; and dry contracted skin.

Treatment.—That of fever generally. Moderate the excitement when high, as in fever. When the eruption is full out upon the skin, and there is no perspiration, cold water may be used freely to the surface. When the eruption is disinclined to come out, and torpor without signal typhoid tendency prevails, the subcarbonate of ammonia may be used with much prospect of benefit. Nitre and cinchona bark in combination, as mentioned in malignant small-pox, will be found applicable in the typhoid form of the disorder; the mineral acids too may be ordered; and the frequent use of acidulated gargles is called for. It is often necessary to syringe the throat of children, or to apply more stimulant solutions in case of a sloughing appearance of the tonsils.

℞ Hydrargyri oxymuriatis gr. vj.
Mellis rosæ f. ℥ij.
Aquæ puræ f. ℥vi.

Fiat solutio; tonsillis ulceratis sæpe applicetur parvis quantitatibus ope penicilli.

Take of oxymuriate of mercury six grains, honey of roses two fluid ounces, water six fluid ounces. Make a solution, of which apply a small quantity frequently to the ulcerated tonsils by means of a hair pencil or sponge.

Blisters are sometimes called for in these and other eruptive complaints; but they ought to be used with some reserve, when there is a gangrenous or highly typhoid tendency in the habit, as in this case they are apt to produce sloughing and exhausting sores.

As a consequence of scarlatina we frequently find dropsical swellings of the skin in different parts of the body; and sometimes dropsical accumulations in the cavities. These would seem to result from the exhausted state of the exhalant vessels on the surface, they having been stimulated too much in the inflammatory period of the disease. A difference of opinion has prevailed with respect to the method of treating this kind of dropsy following scarlatina, some recommending bleeding, while others prescribe tonics. Perhaps we should be guided in this, as in other cases, more by the attendant circumstances than by abstract considerations. Where there is much of arterial action in connexion with the œdema, we ought to be careful of introducing tonics with much freedom; at the same time the debilitated condition of the system and of the exhalants worn down by protracted disorder ought to be taken into the account. It is worthy of remark that Dr. Gregory, who spoke highly of the bleeding and depletory plan of treatment (under these circumstances), in his lecture on dropsy states, in his Practice of Physic, that he has met with several cases which appeared to indicate the propriety of bleeding and purging, but which resisted both, and ultimately yielded to bark and aromatic confection. Dr. Uwins speaks of the very gradual introduction of foxglove into the system under these circumstances as calculated to meet both demands of reducing arterial irritation and obviating lymphatic debility. When foxglove is used with these intentions it should be commenced in doses (for a child four or five yeare old) of two or three minims, and increased to eight or ten by an additional minim at each dose. See *Dropsy*.

369. *Plague.* Pestis.—We have been so pleased with the succinct account which Dr. Gregory gives of the peculiarities, and habits, and circumstances of the plague, that we shall take the liberty of extracting the whole section of his book which refers to this subject; referring the reader to its more enlarged consideration under the words PLAGUE or QUARANTINE in this Encyclopædia.

The plague, classed by Dr. Cullen among the exanthemata, is yet, in strict nosological language, a continued fever closely applied to typhus, and therefore demanding notice more particularly in this place. It may be viewed indeed, without over-refinement, as the link which connects these two great classes of idiopathic fevers. In its mode of propagation it resembles the exanthemata. In its symptoms and progress we shall trace an obvious resemblance to those of typhus.

The historical details connected with this very singular disease are highly interesting. The ancients do not appear to have been acquainted with it; but it must be confessed that its origin and early history are involved in much obscurity. For many centuries past it has been endemic on the shores of the Mediterranean; and though it has occasionally shown itself in other latitudes, as at Moscow in 1771, and in this country in 1665, yet in that situation only is it at all times to be met with. Grand Cairo may be considered as the great nidus of the contagion of plague; and from this point, at particular seasons, it spreads with a malignity scarcely to be estimated. The interest with which such a disease must at all times be viewed has been much heightened of late years from the circumstance of its having appeared in our own settlements (in 1813 at Malta, and in 1816 in the Ionian Islands), and been subjected there and in Egypt to the observations of our own countrymen. The symptoms of this disease, the peculiarities in the laws of the contagion of the plague, and the circumstances which appear to favor its diffusion, and the consequent appearance of the disease as an epidemic, are the points to which our attention will, in this chapter, be principally directed.

A feeling of great languor and lassitude usher in the attack of plague, which for the most part happens towards evening. There is always a cold stage, though it is seldom of long duration. Heat of skin, head-ache, and giddiness succeed. The pain of the head is referred to the temples and eye-brows. The eyes appear heavy, dull, and muddy. The expression of the countenance changes in a remarkable manner. Sometimes there is a wild and furious look; sometimes a look claiming commiseration, with a sunk eye

and contracted feature. The most striking of all the early symptoms of plague is the staggering, and the sudden extreme prostration of strength. A strong tendency to void the urine is generally noticed. The stomach is very irritable, and rejects almost every thing presented to it. The tongue is white and moist. The bowels are sometimes torpid, and at other times loose, the evacuations being always highly offensive. The speech faulters. The pulse is at first small, hard, and quick; but, after the appearance of buboes, it often becomes fuller and softer. It is sometimes intermittent. In point of frequency its average may be stated at 100. The heat of skin is seldom very intense. The head is occasionally perfectly clear and collected. At other times stupor occurs immediately after the formation of the hot fit. Some cases of the disease are ushered in by a violent fit of mania. The greatest indifference with regard to recovery prevails, and is always reckoned a most unfavorable symptom.

After one, two, or at furthest three days, pains in the groins and axillæ announce the formation of buboes. These pains are often highly acute, and, unless speedily followed by the swelling of the gland, the patient dies delirious. In women the axillæ, in men the groins, are chiefly affected. Carbuncles appear at the same time, but indifferently on all parts of the body. Petechiæ and vibices are much more frequent than carbuncles, which it appears do not occur above once in twenty cases. The fatal termination is sometimes preceded by violent hæmorrhages from the mouth, nose, or intestines.

The duration of the disease is very various. A few cases are on record where the patient died within a few hours from the invasion. To many it proves fatal during the first paroxysm or period, which includes the time from the evening of the attack to the close of the following night. The third and fifth days are however, upon the whole, those of the greatest danger. The former is the usual period of the appearance of bubo; the latter of the abatement of the febrile symptoms. If the patient survives the fifth day, and the bubo is fully formed, he may be considered as nearly out of danger. The convalescence indeed is always very tedious, from the extreme debility which the disease leaves; and the patient's life is not unfrequently again put into imminent hazard from the occurrence of gangrene in the extremities.

Such is the train of symptoms which characterises this disease. To form some idea of the extent of the mortality which it occasions, I may mention that out of 700 persons attacked by it in the district of Leftimo in Corfu, in 1815, seventy were saved, and 630 died. It is curious however to observe that, occasionally, this very formidable disease assumes a totally different character. The mild form of plague is not peculiar to any families, or classes of persons, or districts, or periods of the epidemic. It is more commonly met with towards its decline, but it is observed occasionally even from the very first. Buboes form in this variety of the disease about the usual period, generally with a good deal of inflammation, and go on to suppuration. Carbuncles and petechiæ, however, are never observed to attend it. It is marked by the same set of febrile symptoms as characterise the malignant form of the disease, but they are all milder in degree. It terminates occasionally by a critical discharge, but does not appear to require, or to be at all affected by, any kind of medical treatment. A few cases have been recorded of plague appearing in the form of buboes, without any constitutional affection.

A circumstance of some importance, as tending to point out the analogy between the plague and other forms of continued fever, has been taken notice of by Sir James M'Grigor, in his Medical Sketches of the Expedition from India to Egypt:—I mean the effect of season, ventilation, and peculiarities of soil, in modifying the character of the symptoms. The cases of plague which occurred in the cold months of the year were marked by an inflammatory diathesis. Those which were sent in from crowded hospitals were attended from the very first with low or malignant symptoms. Those which occurred when the army was encamped near the marshes of El-Hammed showed a kind of remittent or intermittent type.

Some dissections have been made of the bodies of persons who have died of the plague, but they afford little or no instruction. The few morbid appearances noticed were met with in the cavity of the abdomen.

In the malignant form of plague every variety of treatment has been tried, but with so little effect that it may be considered as a disease nearly beyond the reach of medicine. The violent head-ache which occurs during the first twenty-four hours seems to point out the propriety of blood-letting, and is recommended by the general custom of the Turkish practitioners; but in the hands of English surgeons it proved of no avail. In the cases in which it was tried it did not appear, however, to make matters worse. The blood first drawn was generally sizy, but never afterwards.

Where mercury can be brought to affect the mouth it appears to be of some service, but it is seldom that sufficient time is afforded for this specific effect of the remedy. Ether and laudanum are valuable medicines in allaying the irritability of the stomach. Wine and opium are of no use during the violence of the disease, and bark can seldom be retained. This is much to be regretted; for wherever it can be made to stay on the stomach, even in those severe cases where carbuncles and vibices appear, its good effects are conspicuous. Camphor, bark, and wine are given with much advantage during the period of convalescence. Emetics, purgatives, and the cold affusion have been tried, but it does not appear that they are of any particular service. Diaphoresis can seldom be produced, owing to the disposition to vomit; but wherever it can be procured the symptoms seem to be mitigated by it.

Great attention is always paid to the local treatment of the buboes. They seldom go back, and it is usual, therefore, to employ means with the view of accelerating their suppuration. For this purpose the Turks are in the habit of applying the actual cautery, but it did not answer in

the practice of our army surgeons. The irritation occasioned by it was excessive, so as sometimes to hasten the patient's death. Blisters and poultices are certainly preferable; but, upon the whole, it is quite obvious, that as little can be done in the way of surgical treatment in the plague as by internal medicines.

The general resemblance which plague bears to those malignant forms of typhus fever, which are occasionally witnessed in cold countries, must be abundantly obvious. The great distinction between them lies in the occurrence of buboes; in other words, in the tendency which plague has to affect the lymphatic system. This line of distinction, however, is so broad, that plague is to be viewed as a continued fever, allied indeed to typhus, but differing from it in the important circumstance of having its origin in specific contagion. That the plague is a highly contagious disease cannot for a moment be made a matter of dispute; but some physicians have maintained that it is not a fever sui generis, generated by a specific contagion, but only an aggravated form of typhus, in support of which opinion it has been argued, that cases of typhus complicated with buboes have sometimes been observed in this country. This idea, however, is entertained only by a few, and the doctrine of a specific contagion in plague is that which is now generally received. Its laws have been investigated with some accuracy, and the following seem to be the most important of those which have hitherto been ascertained:—

1. The latent period of the contagion of plague, or that between communication with an affected individual and the appearance of symptoms, varies in different cases. It is scarcely ever less than three days, and it seldom exceeds six. Instances are recorded of the disease not appearing until the tenth day, but these cases are rare.

2. The contagion spreads to a very small distance only from the body of the patient. The consequence of which is, that the disease is seldom if ever communicated, except by actual contact.

3. The dead body does not communicate the disease so readily as the living. This, I understand, is well known in Turkey, but that the contagion is sometimes received from the dead body cannot, I apprehend, be doubted.

4. The contagion of plague is readily imparted to fomites, in which it may lurk for a very long time, more particularly if secluded from the air.

5. Re-infection is occasionally observed, but, upon the whole, it is not common. The individuals throughout Turkey, who are employed about the persons of plague patients, have, with very few exceptions, undergone the disease. Sufficient instances, however, are met with of persons taking the disease a second time, and even dying of the second attack, to make all who have previously had it cautious in their intercourse with the affected.

6. Plague, like the small pox, may be taken by inoculation. The experiment has been tried in several instances, but in none has it succeeded in mitigating the disease. Dr. Whyte in 1801, and Mr. Van Rosenfeldt in 1817, paid the forfeit of their temerity with their lives. The former died on the fourth, the latter on the second day of the disease.

Plague I have stated to be endemic in Egypt; and both at Cairo and Constantinople cases of the disease are almost always to be met with. In other words they occur sporadically in those places. While the English army was in Egypt, in 1801, cases of plague were continually occurring; but the judicious regulations which were adopted prevented the disease from spreading, and the troops suffered but little from it. At Malta however in 1813, and in the Ionian Islands during the years 1815-16, the plague raged epidemically; and from very early times it has been observed that, at particular seasons, the plague disseminates itself with extraordinary malignity. To this nothing can give any effectual check but the enforcement of severe measures by the strong arm of military power. At Marseilles in 1720, at Messina in 1743, at Grand Cairo in 1759, and on various other occasions, when the plague was suffered to advance without any such control, the ravages which it committed were of incalculable magnitude. The rigid seclusion of families, the immediate removal of all suspected cases to quarantine, and of all decided cases to the lazaret, are the preventive measures of most obvious importance.

Many enquiries have been instituted with the view of determining, if possible, what the circumstances are which render the plague epidemic at certain seasons. Some particular constitution of the air is generally supposed to occasion it, but what that is never has been, and probably never will be ascertained. The extremes both of heat and cold are said to be unfavorable to the propagation of plague; but this opinion must be taken with some limitations. The plague raged in summer at Malta, in the winter months at Corfu. Nor is it clear that it is upon any peculiar state of dryness or moisture in the atmosphere that the phenomenon depends, though indeed there is a popular belief all over the Levant that the heavy dews which begin to fall about St. John's day check the advance of the plague. To this circumstance is attributed the curious but well ascertained fact that, though the disease had been previously raging in the town, the inhabitants may, after that day, leave their homes, and mix in society with comparative security.

It is a common remark in the Levant that the advances of the plague are always from south to north. When the plague is at Smyrna, the inhabitants of Aleppo handle goods without precaution, and have no fears of contagion. When the disease, on the other hand, is at Damascus, great precautions are observed, and all the Frank families hold themselves in readiness to shut up, or to leave the town. An epidemic plague, therefore, nearly always begins at Grand Cairo, spreads to Alexandria, and from thence through Syria to Smyrna and Constantinople.

The seeds of the plague being always present in Turkey, if it were not for these peculiarities in the laws of its contagion, that country must have been long since depopulated. Whether the genuine Levant plague could spread in this cli-

mate is a point upon which physicians are not agreed. The general opinion is, that it might so spread under particular circumstances, and, therefore, that the quarantine regulations established by the legislature are absolutely necessary for the protection of these countries.

370. *St. Anthony's fire.* Erysipelas.

Symptoms.—This cutaneous affection is often ushered in with sickness, and much depression of animal power; the pulse is quick and sometimes hard; and, after a day or two, redness and tumefaction appear about the face and neck, which extends to the eye-lids, and closes the eyes; this continues to increase for some days, often accompanied by great pain in the head, and delirium, and at length it terminates in desquamation. Metastasis is very liable to take place in erysipelas to the brain, and sometimes to the lungs, producing in the first case delirium, and in the pulmonary translation difficulty of breathing and general pulmonary symptoms. The brain, however, is by far the most frequent seat of translated erysipelas. The head and face are not the only parts obnoxious to erysipelas; the legs sometimes are the seats of the disorder, and at other times different portions of the body's surface. For an account of that species of erysipelas which Dr. Cullen calls the phlyctænodes, see the *Appendix*.

Causes.—Irritations in the stomach and bowels; vicissitudes of temperature; over eating or drinking; suppressed evacuations, as of the menstrual discharge. In some there appears a more than common disposition to plethoric fulness and erythematic inflammation; and these are the subjects that are predisposed to erysipelas. Erysipelas seems sometimes contagious, and often endemic, as if from some peculiarities in the air.

Distinction.—Gout and scarlet fever are the complaints with which idiopathic erysipelas is most nearly allied in appearance; but these are easily distinguished from it by their accompanying tokens.

Prognosis.—In general favorable, but, not seldom, far otherwise; the kindly symptoms are, the comatose and delirious states leaving the patient as the efflorescence of the skin proceeds; this last shortly ending in a yellowish appearance, and not producing much vesication. If the fever continue urgent after the appearance of the efflorescence, assuming a typhoid type, and being protracted beyond the seventh day; if then the skin redness suddenly recede, and internal tendencies become marked with prostration of strength, and weak or intermittent pulse, the patient must be considered in a highly dangerous condition.

Treatment.—For the most part it is best to begin the treatment by an emetic; this being directly serviceable when the disorder is occasioned by stomach and bowel irritation; and indirectly, when it shall have had another origin, by reducing action. When the subject of the disorder is in a high condition of sthenic excitement, robust in his constitution, and breathing the pure air of the country, we may have recourse to pretty large blood-lettings; but these ought to be instituted with much reserve in crowded hospitals or cities, and when the patient is not constitutionally strong. In this case we must be content with saline purgatives or diaphoretics. Local blood-letting is seldom advisable in erysipelas: indeed, leeches often bring the disorder on when there is a constitutional bias towards its formation. When the frame seems sinking, and the disorder tends internally, give subcarbonate of ammonia; and, when typhoid symptoms are urgent, bark and the mineral acids are called for. In respect to topical applications, the repellent kinds for obvious reasons must be used with much reserve, and only then resorted to when the subject is young and vigorous, and the skin affection is at a distance from the head; sprinkling the surface with flour, or starch, or oatmeal, will sometimes take off the distressing burning of the skin by gradually absorbing the acrimonious moisture that oozes out from the inflamed vessels. In cases of internal disposition, warm fomentations or spirituous applications may be resorted to in order to restore the cutaneous action.

371. *Miliary fever.* Miliaria.—The definition gives the symptoms with sufficient correctness. The great characteristics of the disorder are the odor of the perspiration, and the præcordial anxiety. The eruptions are like millet seeds, sometimes red, and sometimes more white or pale-colored. They are occasionally produced by stomach disorder, but most commonly brought on by a heating, irritating regimen; by an overload of bed-clothes; and by confined heated apartments: and are, therefore, of comparatively unfrequent occurrence, in this day of antiphlogistic good sense. Their prevention and treatment are sufficiently obvious. In case of retrocession, succeeded by internal symptoms of an alarming kind, ammonia and cordials must be resorted to. In all cases it will be necessary to keep the bowels free, while attention is at the same time given to support the strength by bark and acids.

'To prevent the disease arising in pregnant women, costiveness,' says Dr. Thomas, 'ought to be carefully guarded against, and when in child-bed they should strictly observe a cool regimen.'

372. *Nettle-rash.* Urticaria.

Symptoms.—In addition to the definition it may be stated, that large wheals are occasionally observed on the skin as well as the small spots; and that the disorder sometimes lasts, or disappears, and appears again for some months.

Causes.—Exposure to colds and heats will sometimes bring on urticaria; at other times it is occasioned by substances taken into the stomach. Shell-fish will, in some individuals, invariably produce a nettle-rash; and these frequently occurring idiosyncracies have induced pathologists to conclude that in all cases, even of the more common and decided nettle-rash, the digestive organs are in some measure concerned in its production.

Treatment.—An emetic may generally be administered with propriety; and afterwards cooling aperients. In the chronic disease we are informed, that an infusion of serpentaria may be employed with advantage in the proportion of two drachms to a pint of water.

373. *Vesicular eruption.* Pemphigus.—This vesicular eruption is of rare occurrence, of uncertain origin, and does not seem to be influenced by medicine on any other principle than of keeping the stomach and bowels clear, and meeting the incidental excitement that may be present by a cooling regimen. Should the attendant fever assume a typhoid character, bark, mineral acids, and syrup of poppy, may be given. Pemphigus does not appear to be contagious.

374. *Thrush.* Aphtha.—The aphthous eruptions, that appear in the mouth and fauces, are generally accompanied by the same condition of parts, through the whole length of the intestinal canal, or at least through a considerable portion of it. They are merely indices of irritation growing out of debility, and are not under the control of any specific agents. When they take place in the diseases of old people, that have been of long standing, they are, for the most part, signs of approaching dissolution. The aphthæ of children generally denote a disordered state of the mucous tissues of the stomach and bowels. Dr. Thomas speaks of a chronic thrush as very common in the West Indies, and accompanied by a cachectic state of the general system. Aperients and detergent gargles are the remedies for aphthæ generally, and the mineral acids taken internally, according to the extent of excitement or degree of debility: but to attempt their removal, without removing their cause, is like an attempt to whiten an Ethiopian's skin.

375. Order IV. Hæmorrhages. Some remarks will be found on the general doctrine of hæmorrhage in the introductory disquisition, and we shall have to recur to the consideration in the article Physiology, when the forces which circulate the blood are under discussion. It is only for us now to go through the several genera contained in the order; merely reminding the reader that hæmorrhage takes place under opposite states of the system as to power, and that discharges of blood do not always imply actual rupture of the vessels containing it.

376. *Bleeding from the nose.* Epistaxis.—Hæmorrhage from the nose is generally an effort of nature, to relieve a congested or plethoric state of the blood-vessels about the head; and, unless immoderate, it is for the most part inexpedient to interfere with the discharge. When much general excitement prevails, the antiphlogistic regimen is to be adopted; if obstructed viscera, as of the liver or spleen, have caused it, emulgent purgatives are to be employed; and, in cases of old age and great debility, tonics and astringents may be required internally. The best local application are dossils of lint, or the scrapings from a beaver hat, put up the nostrils so as to plug them and permit a coagulum to be formed; the lint may be dipped in strong solution of common alum or sulphate of zinc. The sudden application of cold to any part of the body will sometimes stop epistaxis; hence the vulgar remedy of a key put down the back. Plunging the head in a pail of cold water, impregnated with salt, has been had recourse to with success when other plans have failed. It is a general observation, and one as old as Hippocrates, that persons who have bleeding at the nose when young are liable in after life to hæmoptysis and consumption.

377. *Spitting of blood.* Hæmoptysis.

Symptoms.—The definition is very accurate; there is sometimes a hard full pulse at the time of the discharge; the irritation is usually just at the top of the larynx, and there is often a saltish taste perceived.

Causes.—Scrofulous laxity, with plethoric fulness of vessel, predisposes to hæmoptysis; and the predisposing age is from sixteen to thirty-five. A narrow chest gives too a predisposition to the disorder, as does an obstructed state of one or more of the viscera; or a suppression of an accustomed evacuation; or obstructed perspiration.

The *exciting causes* are, violent exercise of the body or the lungs; excessive heat; the impure air of crowds; and mental agitation. The air, also, not otherwise impure, may be too much rarified.

Distinction.—From hæmatemesis, by the blood being frothy and florid instead of dark and grumous; by its coming up in the act of coughing rather than vomiting; on this point there is, however, occasionally some difficulty, from the circumstance of vomiting being a frequent attendant upon hæmoptysis; and by its being in smaller quantities than when it comes from the stomach.

Prognosis.—Unfavorable when the discharge indicates a phthisical state or tendency in the lungs, where it is not followed or preceded by much constitutional irritation. When it leaves behind it no difficulty of breathing, cough, nor pricking pain in the chest; and where there is no scrofulous habit, nor malconformation of the pulmonary organs, nor hepatic derangement, the prospect is favorable as to thorough and permanent recovery. It should be remarked, that the danger is in most cases rather remote than immediate, since death very seldom follows upon the mere quantity of blood discharged. Dr. Heberden tells us that he never witnessed but one case of a fatal termination of hæmoptysis from the actual loss of blood.

Treatment.—With a hard and jerky pulse, as it is called, and when the hæmorrhage is very considerable, repeated bleedings are called for, as in pneumonia; but it is by no means necessary to bleed in all cases of hæmoptysis. The antiphlogistic plan of treatment is invariably required when the hæmorrhage is of an active kind; heat in all forms and shapes must be avoided, and quiet enjoined. Saline purgatives are requisite, to which may be added tincture of digitalis; or this last may be given alone in doses of ten, gradually increased to thirty minims. The nitrate of potass is a good medicine in active hæmoptysis. The sulphuric acid is an excellent medicinal.

℞ Acidi sulphurici diluti ♏ xv.
Syrupi papaveris f. ʒj.
Infusi rosæ f. ℥iß.
Fiat haustus.

Take of diluted sulphuric acid fifteen minims, syrup of white poppy a fluid drachm, infusion of roses a fluid ounce and a half. Make them into a draught.

Should the bleeding continue in defiance of the above treatment, more active astringents will be called for, and one of the most efficacious is the acetate of lead.

℞ Plumbi acetatis gr. j.
Opii pulveris gr. ß.
Micæ panis q. s.

Fiat pilula parva; ter quaterve in die sumenda.

Take of sugar of lead one grain, powder of opium half a grain, crumb of bread enough to make a small pill, to be taken three or four times a day.

When this medicine is had recourse to, acids ought to be laid aside, otherwise bowel affections are likely to follow its use.

Blisters to the chest and back will occasionally be found useful in exciting a vicarious irritation. But for the most part it is improper to apply them till the vascular irritation has been got under by other means.

378. *Pulmonary consumption.*—Dr. Cullen marks this as a mere sequela of hæmoptysis, but it often commences, proceeds, and becomes incurably confirmed, without any spitting of blood; and often this last is rather an accompanying symptom than a preliminary condition of phthisis.

Symptoms—The first indication of this disorder is usually a short, dry cough, with impeded and hurried breathing, especially upon exercise either of the body or the lungs; an indolence and langour insensibly creep upon the patient's habits and feelings, and he is observed to lose flesh; he is more than commonly also sensible to alternations of temperature, and in this state, between positive health and actual disease, the patient will often continue for some length of time. But the breathing afterwards becomes more and more difficult; and the cough more decided; now too, pains are felt in the chest; a difficulty in lying on one side is experienced; the emaciation becomes more conspicuous, and hectic irritation is decidedly established; burning heats are felt in the palms of the hands and soles of the feet; the pulse becomes not only quick, but hard; the urine high colored, and throws down a branny sediment; and the tongue, from being at first covered with a whitish crust, now appears clear and red. The two daily exacerbations of the hectic fever occur; the face comes to be marked at the time with a circumscribed spot of red. Morning perspiration too, principally about the neck, head, and shoulders, comes to harrass the consumptive subject; and, at this stage of the complaint, the white of the eye assumes a pearly appearance, which is remarkably and mournfully opposed to the swimming brilliancy of its transparent part. Now too, the sputum has become unequivocally purulent; the stomach fails of its retaining power, even though the appetite may not be deficient; the emaciation becomes extreme; the cheek-bones frightfully prominent; the eyes hollow and languid; the nails incurvated; the hair falls off; œdematous swellings of the ancles take place, and at length, a diarrhœa occurs, which last is usually a prelude to speedy dissolution: and the patient often dies, while he is still full of hope with respect to his state, and planning schemes for his enjoyment in life. This last feature, however, is not an invariable one of the disease; in some cases, the patient is conscious of his approaching end, and resigned to his fate; at other times he wars against the disorder, and is worried by present irritation and gloomy prospects.

The above account of the progress of the disease we have taken, as we have many others, from Dr. Uwins's Compendium; but in the present instance we shall add the symptoms of pulmonary consumption from two other modern authors; for it is often useful to contrast and compare the accounts of different writers, and the student cannot take too much pains in familiarising himself with the physiognomy of this frequently occurring malady. The two other physicians from whom we now extract are Dr. Gregory and Dr. Thomas.

A slight tickling cough is one of the first symptoms that mark the formation of tubercles in the lungs. The patient is languid, and has the feeling of slight pains in some part of the chest, when he ascends a flight of stairs, or takes any considerable exercise. The pulse will commonly be found, even in this early period of the disease, somewhat accelerated. These symptoms, however, being very slight, are often overlooked, both by the patient and his friends, until the occurrence of hæmoptysis, which may be said to characterise the first stage of phthisis pulmonalis, with as much certainty as purulent expectoration does the second.

By degrees the cough becomes more and more troublesome. A fixed pain in some part of the thorax, or about the pit of the stomach, will now be complained of. Respiration is hurried, and the patient is unable to expand the chest, even in the slightest degree. There is difficulty in lying on one or other side, or sometimes on the back, and, at length, the nature of the disease is put beyond doubt by the occurrence of purulent expectoration, and hectic fever.

The expectoration of a thick pus, generally in the form of globular lumps, of a straw color, occasionally tinged with blood, and always more or less mixed with mucus, is indeed the peculiar feature of this disease; but perhaps too much stress has been laid upon the necessity of distinguishing in pulmonic diseases between the different kinds of expectorated matter. An extensive observation of disease will show that its appearance varies extremely, not only in different individuals, but even in the same individual on different days, and that its qualities may alter, without materially altering the danger, still less the nature of the disease.

Dr. Gregory goes on to describe the peculiarities of hectic fever, and then continues his history in the following manner:—

Such are the characters of hectic fever; and, as they are always most strikingly displayed in the progress of tubercular consumption, they will seldom fail, in conjunction with the local symptoms already enumerated, to afford evidence which will be sufficiently decisive of the nature of the disease. There are some symptoms, however, which occasionally occur in the progress of consumption, which require a separate notice. I may first mention that it is not uncommon to

have in this disease an accession of acute pleurisy, or of inflammation of the peritonæal surface of the liver. Further, as phthisis frequently supervenes on other diseases, its symptoms are sometimes so complicated with those of the primary disorder, that much discrimination is required in forming a judgment as to the true nature of the case. In many instances the symptoms of such diseases correspond very closely with those of phthisis, and this applies more especially to certain morbid states of the larynx and trachea, and to some obscure affections of the heart and great vessels.—I have already alluded to the hoarseness which attends consumption, and to that sympathetic affection of the larynx which is so frequent in its latter stages.

Dropsy, particularly of the cellular membrane, is by no means uncommon in this disease. A degree of œdema of the feet and ancles is sufficiently decisive of it, but it frequently extends also to the legs and thighs. This has commonly been attributed to debility, to that same relaxation of the capillaries to which we are in the habit of ascribing colliquative perspirations. But this theory is doubtful, because in many cases, where an equal or even a greater degree of muscular weakness prevails, there is no appearance of dropsical effusion. Dr. Hastings is inclined to attribute it to the mucous membrane of the bronchiæ becoming implicated in the disease.

Dr. Thomas says the incipient symptoms of phthisis will vary with the cause of the disease; but when it arises in persons of a strumous temperament, or from tubercles, it is mostly thus marked; it begins with a short dry cough that at length becomes habitual, but from which nothing is spit up for some time, except a frothy mucus that seems to proceed from the fauces. The breathing is at the same time somewhat impeded, and upon the least bodily motion is much hurried; a sense of straitness with oppression at the chest is experienced; the body becomes gradually leaner, and great languor with indolence, dejection of spirits, and loss of appetite prevail.

In this state the patient frequently continues a considerable length of time, during which he is, however, more readily affected than usual by slight colds; and, upon one or other of these occasions, the cough becomes more troublesome and severe, particularly by night, and is at length attended by an expectoration, which towards morning is more free and copious. By degrees the matter which is expectorated becomes more viscid and opaque, and now assumes a greenish color, and purulent appearance, being on many occasions streaked with blood. In some cases a more severe degree of hæmoptysis attends, and the patient spits up a considerable quantity of florid frothy blood.

The breathing at length becomes more difficult, and the emaciation and weakness go on increasing. With these the person begins to be sensible of pain in some part of the thorax, which, however, is usually felt at first under the sternum, particularly on coughing.

At a more advanced period of the disease a pain is sometimes perceived on one side, and at times prevails in so high a degree, as to prevent the person from lying easily on that side; but it more frequently happens that it is felt only upon making a full inspiration or coughing. Even where no pain is felt it often happens that those who labor under phthisis, cannot lie easily on one or other of their sides without a fit of coughing being excited, or the difficulty of breathing being much increased.

Dr. T. then goes on to notice the coming on of hectic, and proceeds to say, that, from the first appearance of hectic symptoms, the urine is high colored and deposits a copious branny red sediment. The appetite, however, is not greatly impaired; the tongue appears clean; the mouth is usually moist, and the thirst is inconsiderable. As the disease advances the fauces put on rather an inflamed appearance, and towards the termination are often beset with aphthæ, and the red vessels of the tunica adnata become of a pearly white (this last sympton and appearance is remarkably characteristic of phthisis). During the exacerbations a florid circumscribed redness appears on each cheek; but at other times the face is pale and the countenance somewhat dejected.

At the commencement of hectic fever, the belly is usually costive; but in the more advanced stages of it a diarrhœa often comes on, and this continues to recur frequently during the remainder of the disease; colliquative sweats likewise break out, and these alternate with each other and induce vast debility. The degree of heat in which the patient is kept has often a great effect upon the diarrhœa; for by exposing him to cool air in the morning the sweat may be much diminished, but the diarrhœa will be increased; and on the other hand, if the diarrhœa be relieved by opiates and astringents, the sweating will be aggravated; thus they frequently alternate for a long time, but in a few instances they are both severe at once.

In the last stage of phthisis the emaciation is so great that the patient has the appearance of a walking skeleton; his countenance is altered, his cheek bones are prominent, his eyes look hollow and languid, his hair falls off, his nails are of a livid color and much incarcerated, and his feet and ancles are affected with œdematous swellings. To the end of the disease the senses remain entire, and the mind is confident and full of hope. It is indeed a happy circumstance attendant on phthisis, that those who labor under it are seldom apprehensive or aware of any danger; and it is no uncommon occurrence to meet with persons, laboring under its most advanced stages, flattering themselves with a speedy recovery, and forming distant projects under that vain hope.

Shortly before death the extremities become cold. In some cases a delirium precedes that event, and continues until life is extinguished.

Causes.—Scrofula constitutes the predisposition to true or tubercular phthisis; a particular formation of the body likewise predisposes to it, as long neck, high shoulders, and narrow chest; which, when they occur with a scrofulous diathesis, give a manifest tendency to the production of phthisis. The exciting causes are cold, and every thing which may mechanically, as it were, injure the lungs, such as the occupations of

needle-pointing, flax-dressing, hair-powdering, &c. We are told by Dr. Willan that hair-dressers, bakers, masons, bricklayers' laborers, laboratory men, coal-heavers, and chimney-sweepers, as well as dressers in flax and feathers, and workmen in the warehouses of leather-sellers, are liable especially to pulmonary disease. It seems to a certain extent contagious. On the continent it is generally supposed very contagious, but in this country the opinion is generally scouted. Various diseases will excite the pulmonary tendency into action, as the catarrhal irritation of the exanthemata, especially measles; asthma, whooping-cough, bronchitis, pneumonia, hæmoptysis, will all and each of them occasionally come to be productive of suppurative lungs in the common way of inflammatory disorganisation, or will excite the tubercular predisposition into the specific disorder in question; for genuine phthisis, we may repeat, is invariably tubercular. Tubercles are small tumors, which have been supposed by some to be indurated lymphatic glands; but, although this is not the case, their formation and progress seem to have some intimate connection with the workings of the lymphatic system; they are at first indolent and harmless, but, becoming inflamed, they suppurate and form little abscesses, which communicating with the air-cells of the lungs, are discharged by expectoration. These bodies vary from the size of a pin's head to that of a garden pea; they are frequently formed through the whole substance of the lungs, but are most usually met with in its upper and posterior parts. In their earliest state they are solid and of cartilaginous hardness. No blood vessels can be traced in them even by a microscope, and the finest injection does not penetrate them. They are situate, not in the air-cells, but in the proper cellular texture of the lungs.

Distinctions.—In the latter stages of pulmonary consumption, the disorder is too unequivocally marked to be mistaken for any other. Chlorosis and amenorrhœa, however, simulate the disorder in its early stages, and often terminate in its actual production. In respect to the distinction between pus and mucus, the eye will soon, by use, learn to make it with quite as much accuracy as by any chemical tests; pus, it is merely necessary to say, is more compact in its substance, more opaque in its appearance, sinks sooner in water, and is of a more fœtid odor than mucus. When pus comes to be gradually formed from mucous surfaces, the discharge is often a something between mere mucus and positive purulent matter. This kind of intermediate substance is, however, more common to bronchitis than to tubercular consumption, and its presence may in some measure be taken as a diagnostic mark between the one and the other disease. Between specific or true consumption, and the disorders which commence in common inflammation, and in common suppuration, the distinction must be taken from the slow insidious progress of the former, and from its being accompanied by scrofulous marks. It may in conclusion be noticed that there is often a peculiar and semi sort of voice in the individuals destined to be consumptive, and not unfrequently actual aphonia occurs. The stethoscope has lately been employed by Dr. Davis for ascertaining the various stages of this disease. It was originally introduced by Laennec, and owes it power to the conducting power of a piece of wood which is brought in contact with the chest. By the sound emitted, the practitioner is enabled to determine the amount of the patient's danger.

Prognosis.—Always unfavorable in confirmed tubercular phthisis. We hear talk of ulcers being healed, and consumptive cysts left, as cysts are formed in the brain after hæmorrhagia cerebri, and the disorder thereby for a time stopped; but it is, to say the least, extremely doubtful whether strumous tubercular ulceration that has taken place to any extent can ever be cured either by nature or art. That pus may be expectorated, and the patient recover, we all know; but then this is the pus of common, not of specific inflammation, and takes place after bronchitis, or after pneumonia, not from tubercle. Dr. Gregory, in remarking on the prognosis in consumption, expresses himself in the following manner:—It is unnecessary to treat formally of the prognosis in this disease. The common observation of the world has sufficiently stamped its character as the most destructive disease in this island. (the annual deaths in England by consumptions are calculated at one in five of the whole mortality, and amount therefore annually to about 55,000), and in its confirmed stage almost hopeless. The duration of the complaint, however, it is scarcely possible to define with any degree of accuracy; for a galloping and lingering consumption are almost equally frequent. A French author, speaking of the usual duration of pthisis, informs us that, out of 200 cases, 104 died, within nine months. In many cases there are threatenings of the disease for several winters before the symptoms assume any degree of urgency. They are often checked by the return of mild weather; but perhaps, even in a still more remarkable manner, by pregnancy. The months of January and December are observed to be particularly fatal to phthisical patients. Sometimes they die from extreme weakness, exhausted by the discharge of pus, and the colliquative perspiration and purging; at other times more suddenly suffocated by accumulation of pus in the bronchi, which they are unable to expectorate; and in some rare cases by the rupture of a large blood-vessel in the lungs in consequence of ulceration.

Treatment.—Keeping down irritation constitutes the main principle in the management of phthisis, since it is irritation, superinduced upon predisposition, by which the disorder becomes developed; but then, in attempting to do this, we must recollect that there is often a formidably asthenic condition of frame, under the cover of high action, and that we may come to defeat our own purpose by pulling down too fearlessly. In the catarrhal irritation of incipient phthisis, small bleedings are, however, often imperatively demanded. Counter irritants are also called for, such as blisters, or the antimonial ointment to the chest. It is in this condition of parts and of the whole that the vegetable narcotics, viz. the digitalis, prussic acid, hyoscyamus, conium, and poppy separately, or some of them combined,

will be found applicable; and if the pulmonary excitement partake, notwithstanding its constitutional and specific nature, of a sympathetic character, or is magnified, if not made, by stomach and bowel, or hepatic disorder, then small doses of the blue pill, in conjunction with the narcotics, may be admissible. Gentle laxatives are always to be thought of as part of the curative measures; and some have much faith in the occasional, or even periodical, exhibition of emetics; these last have, however, for the most part been used in the latter or ulcerative stages of the disorder. Regulation of the diet, but more especially of external temperature, is, in the early periods of phthisis, of most important consideration. Warm clothing should be enjoined, especially warmth to the feet; and, when the menaces of the complaint are too unequivocal to be mistaken, we must give up all thoughts of braving it out, or hardening the frames of our patients, lest we add to the already existing irritation. Some, indeed, still pursue the plan, even in the most formidable state of consumptive manifestation, of cold applications to the chest, and other rough processes; and success may, occasionally, have followed their experiments: it must likewise be admitted, that the other plan of confinement and regulating temperature is but too often unavailing. While we keep the apartments of our consumptive invalid in a state of equable warmth, we must, at the same time, guard against those impurities in the air that are likely to be engendered by confining it; and we must at no time raise the heat beyond pleasant endurance. Early removai to more temperate climates, such as the south of France, or Devonshire, in our own country, may be thought of, when the patient's circumstances permit; but the idea of any specific good to be got by these changes, beyond a greater equality of temperature, must be given up. In some cases the journey or voyage may prove useful, by altering the actions of the system, and inducing a new series of movements. Inhaling tar vapor has been highly recommended, but it is for the most part too irritating, and rather applicable to bronchitis than to true consumption; a farinaceous diet should be enjoined, such as arrow-root and light puddings; milk, too, as being nutritious, without being irritating, ought to constitute a large portion of the phthisical patient's support; ass's milk, being more easily assimilated than that of the cow, is, in cases of weak digestion, more beneficial; but in no other way preferable. Shell-fish, especially oysters, seem sometimes abundantly to suit the consumptive. But these are matters that must be rather regulated by individual experience than abstract rule. All inhalations of factitious airs, whether to moderate the excitement of the first stages, or to stimulate and heal ulcers in the latter, are pretty generally now abandoned as unavailable. In that condition of phthisis which is between the hope of the first stage and the absolute hopelessness of the second, chalybeates have been employed with alleged benefit; especially the combination of myrrh, sulphate of iron and alkali, constituting the celebrated mixture of Griffith, and now introduced into the pharmacopœia, under the name of mistura ferri composita. This is especially applicable to the consumptive disorder of chlorotic females, and may, with address and management, be applicable to the states supposed. We do not, however, in the present day, find medicines of this class so available, or even so admissible, as the reports of our immediate predecessors would lead us to believe might be the case. Moderate exercise, so as to keep up a constant tendency towards gentle perspiration, should be enjoined on the consumptive invalid, when it can be used without too much exposure; horse-back exercise was formerly thought to be almost a specific in hectic irritation; swinging is recommended by some, upon the same principle of agitating and exercising without fatiguing. We come to be more and more sceptical with respect to the specific qualities of waters, as well as places, for consumptions. The Bristol waters, for instance, have been extolled and held in reputation as highly antiphthisical: but a practitioner of high name, and not certainly destitute of a disposition to credit remedial processes, and who resided at the hot wells, ridiculed their pretensions to sanative virtue; and another physician tells us, that during a residence of some time, at and near the Bristol hot wells, he cannot charge his memory with a single instance where any person, laboring under a confirmed phthisis, experienced much relief from their use alone.

In the confirmed, or completely suppurative, stage of the disease, it follows from what has been intimated above, that we are not to expect much from art; opening setons or issues in the fleshy parts of the chest may prove of temporary advantage in prolonging life; and should the purulent sputum not come from almost the whole mass of the lungs, or not result from turbercular irritation, this measure might, in some cases, prove radically and permanently sanative. British physicians of the present day look possibly with too little regard upon the power of these counter-irritants. When there is not such a degree of inflammatory irritation as to forbid their use, tonics of different kinds, especially the mistura ferri composita, may be given under these circumstances, and the copaiba may be tried, should we suspect that the purulent discharge was partly, at least, from the bronchial membrane; but it may be repeated, that, in true phthisis of a confirmed kind, it is idle to encourage the expectation of any radical or essential good being accomplished by our present knowledge of the powers of art.—*Dr. Uwins.*

Dr. Gregory's remarks on the treatment of consumption are as follows:—

It is melancholy to reflect how very little this disease is under the control of medicine; and, before I can enter upon the consideration of the principles which are to guide us in its treatment, I must record the failure of every plan for its effectual cure, which human ingenuity has yet devised.

The first principle which it appears to me of importance to inculcate is, that in phthisis active measures cannot be pursued, and that this must be compensated by a strict attention to a number of less circumstances, which in many other

diseases may be neglected without detriment to the patient. We are to bear in mind that consumption, though an inflammatory affection, is principally characterised by its occurring in a scrofulous, which is commonly a weak habit of body, and in an organ loaded with tubercles, the inflammation of which runs rapidly to suppuration. The chief objects of consideration, therefore, are how these tubercles may be either absorbed, or kept in a quiescent state; in what respect their treatment, when inflamed, differs from that of common pneumonia; and how the constitution may be best supported in the protracted suppuration to which their inflammation leads.

The question has been frequently agitated, whether tubercles can be absorbed, and by what medicines that desirable object can be effected. Emetics have been recommended by some, the muriate of baryta by others; but, though there is every reason to believe that tubercles have in some cases dispersed, yet this effect appears to be as completely out of our control, as the manner of their formation is beyond our knowledge. All that can reasonably be expected from medicine is to keep them in a quiescent state, and this is to be done by a strict attention to diet, air, exercise, and by avoiding all those causes which we noticed, in the last chapter, as likely to bring on hæmorrhagy of the lungs.

The diet of a person who has shown a disposition to phthisis, should be nourishing, and calculated to afford strength to the system, without creating a disposition to febrile excitement. For this purpose, farinaceous preparations of all kinds, with milk, should be recommended. Animal broths with fish and a proportion of plainly dressed meat may also be allowed; but all highly seasoned dishes, and food which is difficult of digestion, and fermented and spirituous liquors are to be strictly prohibited. Nothing appears more likely to correspond in every respect with this indication of cure, than the breathing a free and pure air, and its advantages in consumptive cases are generally acknowledged. The patient should be sent therefore to the country, and if possible a situation selected, which is sheltered from cold bleak winds, and where the soil is gravelly.

To those whose circumstances will admit of it, we should advise the removal to a warm climate. Consumption, though far from being uncommon in the southern countries of Europe, is, upon the whole, less frequent there than in cold climates; but between the tropics it is a disease nearly unknown. This consideration, were it not for the danger of the endemics of those countries, would induce us to prefer the Bermudas, or even the West India Islands, as a residence for consumptive patients. But even the south of Europe, particularly the climate of Naples, holds out many advantages, and a timely removal thither, with regularity of living, may be recommended to those who are threatened with consumption, with a fair prospect of overcoming the tendency to the disease.

With the enjoyment of a free and pure air, moderate exercise should also be advised. A sedentary mode of life, and close application to study, or business, have frequently proved the exciting cause of the disease; partly, perhaps, by the bent position in which the thorax is so long kept, but principally from the want of that due exercise which is essential to the preservation of the health and strength of the body. With the view of affording at the same time, both exercise to the body and relaxation to the mind, a journey during the summer months is particularly useful.

When hæmoptysis has occurred, and when the symptoms warrant the belief that inflammatory action is going on in the lungs, measures of more activity must be pursued. Bleeding from the arm has been recommended as a means of putting an immediate check to the progress of the disease; but this is a vain hope, and blood-letting must therefore, at all times, be resorted to with caution, and a due consideration of the habit of body in which consumption occurs. Where the pulse is hard and contracted, and the pain and cough urgent, blood must be drawn from the arm as in pneumonia, and repeated according to the strength of the habit, and severity of the symptoms. At any period of the disease, if pleuritic symptoms supervene with a loaded state of the tongue, blood may be taken away; and commonly a few ounces taken from the arm will be preferable to the application of leeches.

Blisters afford great relief to the cough and tightness across the chest, and they may be repeatedly applied with great advantage through the whole course of the disease. I have never seen sufficient benefit derived from issues and setons to warrant me in recommending them. Active purging is inadmissible, but an occasional dose of castor oil, or of rhubarb, will be found very useful. The mild diaphoretic and expectorant medicines may be exhibited frequently through the day. Attention to the state of the skin, indeed, is very necessary in this disease, as in every other in which the lungs are implicated. A uniform temperature of the body should be promoted by warm clothing. In some cases it may be necessary, during the whole winter, to confine the patient to apartments which are of a regulated temperature.

In this state of disease digitalis is universally employed. That its powers have been extravagantly over-rated, I cannot doubt, but it appears in some cases to quiet the cough, and to be a useful narcotic. In this view, I am inclined to think it preferable to conium, and even sometimes to opium. I have never observed any good effect to follow from pushing the dose of this medicine to such an extent as materially to affect the pulse.

In the confirmed stages of consumption, it will be advisable to support the strength of the system by mild tonics; and the mistura ferri composita, in doses proportioned to the state of the system, is perhaps, under all circumstances, the best form of tonic which can be recommended. In many cases, however, it seems to increase the febrile excitement, and to aggravate the cough and dyspnœa.

Attention must chiefly be paid in this state of the disease to palliate the urgent symptoms. Cough may be alleviated by demulcents; diar-

rhœa may be diminished by chalk, catechu, and aromatics. Both these objects will be promoted, and the further advantage gained of procuring sleep, by the last resource which the art of medicine affords—opium.

In addition to the statements of the above mentioned physicians respecting the curative plans indicated in consumption, and the prospect of good from them, we shall here extract that part of Dr. Thomas's chapter on this subject which relates to change of air and climate.

In our climate, tubercles are evidently induced and accelerated in winter, and retarded in summer. A person gets a dry cough in winter or spring, which goes off as the summer advances, and was regarded as a catarrh, but tubercles were forming: if therefore such a person could be removed to a warm climate, before the winter comes on, he might escape an attack at this period; and, by continuing there for a few years, may be perfectly recovered. Going to a warm climate is not merely avoiding what might be hurtful, it is applying a remedy which has the best chance to prove beneficial.

It may justly be admitted, that the cold and variable temperature of the winters in England is the great source of phthisis in this country, and, when the disorder is once formed, greatly contributes to its fatal termination; and that a warm and equable temperature in some measure prevents the formation of the disease, and, when it has taken place in only a slight degree, possesses some power in retarding its progress.

In the early stage of consumption, that is to say, when suppuration and ulceration have not yet taken place, it appears from the report of Sir James M'Gregor, that the disease was checked by the climate of the Peninsula among those of the army affected with phthisis; but that when suppuration and ulceration had taken place, it ran even a more rapid progress than in England, and the same remark has been made in regard to the East and West Indies.

It is indeed a well-established fact, that a warm climate is only advantageous in cases of incipient phthisis. Persons who have passed the first stage of pulmonary consumption will derive no benefit from a journey to the South of Europe, or elsewhere. Those who labor under confirmed phthisis should never quit their own country. By leaving it, they will lose many comforts; they most probably will be deprived of the attendance of their nearest and dearest friends, as well as that of the medical men in whom they can place confidence, as the English are apt to be prejudiced against foreign physicians: they will, moreover, expose themselves to much anxiety and fatigue, and all this for a vague hope of recovering or prolonging life, an expectation very seldom, if ever, realised. If they remain at home, which they had best do, in all cases of confirmed phthisis, they may live throughout the winter in a regulated temperature.

If the patient's case is one of incipient phthisis only, and his circumstances will admit of removing in due time, that is to say, on the first threatenings of the disorder, from this climate to one in which the temperature is warm during winter, he may comply therewith. The islands of Madeira and Malta, Lisbon, Italy, or the south of France, have been recommended as proper places.

To persons liable to catarrhal or consumptive complaints, the most important properties of the climates of other countries are, warmth and equability of temperature, especially in the winter months. The islands of Madeira and Malta present, numerically, a mean temperature for the winter months, but Pisa, Nice, Villa Franca (very near the latter), and Hieres, are certainly the most desirable places for an invalid.

A female writer of some celebrity informs us, she is convinced by experience, that the lives of many consumptive patients might be saved were they sent by sea to Leghorn, advised to winter at Pisa, cautioned against travelling much by land, and, above all things, interdicted from crossing the Appennines and Alps, which people very frequently do, in order to spend the summer months in Switzerland, one of the most unequal climates in Europe. She thinks that, in pulmonary complaints, Pisa is entitled to a decided preference over Nice, Massa, Florence, Rome, or Naples, or indeed to any other place in Europe, from the beginning of October till the end of April. She was advised to travel over land to Italy, and, therefore, she passed over to France. Nice was recommended to her as the best winter climate, and she therefore spent many months in that city: but experience soon convinced her that she might have adopted a more eligible plan; for long journeys over land on the continent are to consumptive persons dangerous experiments, owing to the accommodations being so very indifferent that it is scarcely possible for an invalid to sleep at an inn out of a great town without suffering. To consumptive persons, and invalids in general, she therefore recommends the going to Italy by sea in a vessel bound to Leghorn, and so wintering at Pisa.

When the patient's circumstances or business will not admit of his removing to a more temperate climate, he must endeavour to pass his winter in some place which is dry and well sheltered from cold bleak winds, where the air is free and pure, and the soil of a gravelly nature. The mild and sheltered vales of Devonshire, but more particularly Sidmouth, Torquay, and Penzance in Cornwall, offer desirable situations of this nature; but the latter may be considered as entitled to a decided preference.

It has indeed been thought by some as equal to any situation abroad; and, therefore, the victim to consumption will not find it necessary to fly an exile from his home and friends to seek a doubtful advantage in a foreign clime.

From a register of the weather at Penzance, by Dr. Forbes, the mildness and equability of the temperature of that country are evident. He observed the maximum temperature of July was only 78° of Fahrenheit, the minimum of December only 33°, and the mean range of the barometer 1·48 inches.

With the enjoyment of a free and pure air, the patient should take daily moderate exercise either in a carriage or on horseback, but more

particularly the latter. By taking it in progressive journeys through different parts of the country, in fair and settled weather, the efficacy of the remedy, great as it may be at other times, would be much increased; for in such a tour the mind would find an ample store of amusement, and be diverted from any train of unpleasant thought. The pursuit of some object at the same time might probably add to the effect. All violent exertions, such as dancing, &c., liberties in diet, and going to crowded public places, are most cautiously to be avoided.

If the disease has made considerable progress, and the patient is thereby prevented from exposing himself out of doors during the winter and spring, he must be contented to live in chambers subject to very little change from the atmosphere, and heated from 62° to 65°, which temperature will be most suitable. A stove may be employed for the purpose, and a preference should be given to one of porcelain (like the German and Russian stove), over one of iron, as a very unpleasant smell is occasioned by the latter. Dr. Buxton is of opinion that in the common shop stove, or ironing stove used in laundries, we possess all that is necessary for the purpose of the proposed remedy.

Under the principle of amusing the mind, and at the same time of having a desirable end to be obtained, many phthisical patients are yearly sent to the hot-wells at Bristol. The waters of these wells have long been extolled for their supposed good effect in consumptive cases; but in my humble opinion they are by no means deserving of the credit ascribed to them, as, during a residence of some time at and near these wells, I cannot charge my memory with a single instance where any person laboring under a confirmed phthisis experienced much relief from their use alone.

That many persons who have been of a phthisical habit have derived benefit from resorting to the Bristol hot-wells, I am ready to admit; but this should not be attributed wholly to the waters. The horse exercise, which is taken daily by such patients, on a fine airy down, where most beautiful views and rich landscapes are presented to the eye on every side; the salubrity of the air; the heathfulness of the situation, and the frequent attendance on the different amusements which are furnished at these wells, and those of Clifton, prove beyond all doubt most powerful auxiliaries. Places of public resort are food to the mind of convalescents, and serve to keep it in the same active state that exercise does the body, preventing thereby that indulgence in gloomy reflection, to which the want of cheerful scenes and agreeable company is apt to give rise in those who are in an indifferent state of health.

The opinion which I have here offered, on the efficacy of the Bristol hot-wells waters, seems however by no means to accord with that entertained of them by a gentleman who some time ago published a dissertation on their chemical and medical properties. On the subject of pulmonary consumption, he observes, that the utility of a journey to Bristol, undertaken while a cure is yet practicable, is demonstrated by hundreds of examples annually, where the disease is prevented in many, and suspended or mitigated in others. I agree, however, with Dr. Beddoes, that the fine things which medical men put into their pamphlets about the water of the places where they constantly or occasionally reside, are to be received with a large share or weight of allowance. Nay, I am decidedly of opinion, that at least three-fourths of the cures attributed to all mineral waters, ought rather to be placed to the account of a difference in air, exercise, diet, amusement of the mind, and the regulations productive of greater temperance, than to any salutary or efficacious properties in the waters themselves.

Short voyages on sea have been much recommended to consumptive persons, under the idea that sailing is of all modes of exercise or conveyance the smoothest and most constant. The good effects produced by sea voyages seem to depend, however, chiefly on the purity of the air, assisted somewhat probably by the occasional vomiting, which persons unaccustomed to be on board of a ship usually experience.

379. *Hæmorrhoids.*—Hæmorrhoids are either formed of varicose hæmorrhoidal veins, or of parts of the internal membrane of the rectum strangulated by the contraction of the sphincter ani, or of interstitial deposits of blood in the cellular membrane of the part under the mucous coat of the intestine. They are divided into external and internal, blind and bleeding, and the differences may be easily understood from their names. They are frequently accompanied by much heat and pain about the loins and in the rectum, which is increased often by the passage of the fæces; when the pile becomes inflamed, and is in this condition strangulated by the sphincter, and the pain which they occasion is often of the most acute kind. When the piles bleed, they frequently do so most profusely, so that the quantity of blood lost in this way will be very considerable.

Causes.—A predisposition to piles is often increased by too free an indulgence in food and wine, by sedentary habits, by suffering the bowels to remain long in a costive state, by the too frequent use of the resinous purgatives, particularly aloes, which seem to have their influence principally directed upon and confined to the lower bowels, by any long continued posture, particularly of sitting too much; and they have occasionally been engendered by riding on horseback. All circumstances which interrupt the free return of blood from the large veins of the abdomen, conduce to hæmorrhoids; hence they are of common occurrence in pregnancy. Persons too with diseased liver are very obnoxious to piles.

Prognosis.—Piles in themselves are seldom attended with much danger, in fact they have been considered as rather salutary occurrences than not, and in some cases they may actually prove so; thus apoplectic tendencies may be suspended by the appearance of the hæmorrhoidal discharge, and other affections may also be diverted or arrested by the vicarious action of hæmorrhoids. Their dangerous tendency consists in the establishment of a permanent thick-

ening of the intestinal membranes, or in their exciting inflammation which shall extend through the cellular membrane, terminate in abscess, and be productive of sinuous or fistulous sores.

Treatment.—The doctrine of active and passive hæmorrhage is especially requisite to attend to in reference to the hæmorrhoidal affection, which, according to the presence or absence of high irritation, demand opposite modes of treatment. When the pain and swelling is considerable, in case of blind piles, it is often necessary to abstract blood, sometimes from the system generally, or rather by the arm; but oftener it will be proper to apply half a dozen leeches locally about the verge of the anus, and to administer saline or refrigerant purgatives. But, for the most part, the best purgatives are sulphur, senna in the form of the confection, castor and linseed oils.

℞ Confect. sennæ,
Sulphuris loti āā. f. ℥i.
Syrup. q. s.

Fiat elect.: sumat coch. ij. parv. nocte maneque.

Take of lenitive electuary and washed sulphur of each an ounce, simple syrup as much as will make an electuary. Let two tea spoonsful be taken night and morning.

℞ Olei lini,
Tincturæ rhei āā ℥ij.
Aquæ menthæ pip. f. ℥iv.

Fiat mistura. Sumat coch ij. magna bis in die.

Take of cold-drawn linseed oil and tincture of rhubarb of each two fluid ounces, peppermint water four fluid ounces. Make a mixture, of which two table spoonsfuls may be given twice a day.

℞ Pulv. potassæ nitrat. ℈ß.
Sulphuris loti ℈ßij.

Fiat pulv. ter in die sumendus.

Take of powdered nitre ten grains, and washed sulphur two scruples and a half. Make them into a powder to be taken two or three times a day.

Cooling lotions are sometimes required, such as half a drachm of white vitriol to half a pint of water; and when the piles are blind or no blood is discharged, but the pain and tension are considerable, the patient will often find much relief by sitting over the steam of hot water. But for the most part a horizontal position is desirable, and lying on the stomach will sometimes afford relief, probably by facilitating in some measure the return of the blood through the abdominal veins.

When the hæmorrhoidal flux is vicarious of constitutional or other irritation, especially when it occurs in a habit the tendency of which is unequivocally gouty, we must be careful of too precipitately stopping the discharge by astringent applications; and, where much debility prevails, the very same kind of medicines will cure which would at times create the disorder. The tincture of muriated iron, in doses of fifteen or twenty drops, will sometimes do much good in mere asthenic or passive hæmorrhoids, and steel is sometimes found to produce the disorder. In long standing hæmorrhoids, when ulcerative inflammation and fistula are threatened, the paste of Ward is occasionally of unequivocal service; so much so, that he who should refrain from prescribing it, because its operation seems to be inconsistent with the demands of the case, would be sacrificing his patient's good to theoretical niceties. This celebrated paste is composed of black pepper, and elecampane root, of each half a pound; fennel seeds and honey, of each one pound. The dose being the quantity of a nutmeg two or three times a day. Small doses also of copaiba balsam prove availing under the same circumstances. The dose may be about twenty drops or fifteen minims rubbed down with yolk of egg or mucilage of gum arabic.

380. *Immoderate flow of the menses.* Menorrhagia.

Symptoms.—Profuse menstruation, and immoderate discharges of blood from the uterus, are in some measure different disorders, since the menstrual secretion and discharge is not blood, being wanting in some of the characteristics of that fluid (See Physiology). Profuse menstruation is also rather relatively than positively a disordered state, since the natural quantity in different women, and even in the same woman at different times, varies very considerably. This discharge may further occur, like all other hæmorrhagic affections, in precisely opposite states, both generally and locally; and all these particulars, of course, require recognition by the medical practitioner. Unless, then, exhaustion takes place from the profuseness of the discharge, or from its occurrence when the female is very low and weak—or, on the other, high irritation, pain, and sympathetic fever, be excited, the case scarcely demands the interference of art.

Causes.—Predisposition to menorrhagia may be constituted by a full plethoric habit, and early sexual propensities—or the disposition to the passive form of the complaint may consist in a habit entirely the reverse, with a lax state of the uterine vessels. The exciting causes are, violent exercise, especially of dancing or walking much; much costiveness, producing exertion in the expulsion of the fæces; exposure to excessive heat; inordinate indulgence in venery, especially at the period of the menstrual flux; violent agitations of mind; repeated miscarriages; and, lastly, organic disorders of the womb, which by absorbing, as it were, the terminal arteries, which open out into the womb, occasion rushes of blood of an alarming nature; and in these cases the menorrhagia is accompanied often by very violent pain. Indeed, structural disorders of the womb, connected with discharges, are among the most formidable and distressing disorders to which the human frame is liable.

Prognosis.—It is not often that the mere discharge occasions a fatal termination, and, when the patient is without structural disorder to occasion the flux, the prognosis is for the most part favorable. Its frequent recurrence, indeed, exhausts the powers and gives accession to dropsical and other diseases, but otherwise menorrhagia is not to be considered as an affection of a formidable nature.

Treatment.—When the action is considerable and the sympathetic fever runs high, blood-letting may be called for; but it is not often that depletion to any great extent is either required or admissible. When much pain accompanies the discharge, cupping on the loins may be productive of considerable advantage. A light diet must be enjoined, and purgatives administered.

℞ Infusi rosæ f. ℥iß.
Magnesiæ sulphat. ʒiß.
Acid sulphur. dil. ♏ xv.
Syrupi papav. f. ʒßi.
Fiat haustus.

Take of infusion of roses a fluid ounce and a half, Epsom salts a drachm and a half, diluted sulphuric acid fifteen minims, syrup of white poppy a fluid drachm and a half. Make them into a draught.

The above formula will abate irritation, prove refrigerant, and act gently as an astringent. When the discharge is more passive or asthenic, the tincture of muriated iron, in doses of fifteen drops in a glass of water, may be given; or the tincture of catechu may be combined with the sulphuric acid, the dose being a fluid drachm of the former to fifteen or twenty drops of the latter. The acetate of lead may be administered in doses of a grain, with half a grain of opium made into pills with crumb of bread; in cases where the discharge is protracted and obstinate, and much enfeebles the patient, applications to the perinæum and hypogastrium of linen rags that have been dipped in vinegar may be had recourse to. Some recommend the throwing up into the rectum cold water, in which some common salt has been dissolved: and cold injections of alum or white vitriol dissolved in water, into the rectum, are in use. In all cases of active menorrhagia the patient should be as much as possible in a lying position, with the thighs rather raised above the horizontal line. Sponges dipped in cold and astringent lotions, and applied externally, will often supersede the necessity of injections. Whey, made by throwing a piece of alum into boiling milk, so as to coagulate it, will often prove a useful drink in menorrhagic disorder.

381. The *menorrhagia alba*, or *fluor albus*, or whites, is a very common and sometimes a very troublesome affection. It is sometimes an attendant upon menorrhagia and sometimes occurs exclusively of this last, occasionally attended by febrile excitement, but more commonly connected with general and local weakness. When this last is the case, tonics and stimulants are demanded; and, among the most efficacious of these, the warm balsams, particularly the copaiba and the tincture of cantharides may be reckoned; both these medicinals will occasionally in the first instance increase the discharge by giving a stimulus to the uterine vessels and general system, but eventually they will prove astringent. The muriated tincture of iron also often proves highly beneficial in asthenic fluor albus, and the uva ursi may occasionally be employed with advantage. Astringent injections in obstinate cases may be thrown up the vagina; but these are for the most part unpleasant to use, and difficult in their management; and the complaint being moreover for the most part quite as much of a general as of a topical nature, the internal medicines are those from which most benefit is to be expected.

Prescriptions.

℞ Tincturæ cantharid. ♏ xv.
Sp. ætheris nitric. f. ʒj.
Aquæ puræ f. ℥iß.
Fiat haustus.

Take of tincture of cantharides fifteen minims, spirit of nitric ether a fluid drachm, water a fluid ounce and a half. Make them into a draught.

℞ Copaibæ ♏ xxv.
Mucilag. acaciæ f. ʒiij.
Terantur simul in mortario sensim affundens aquæ puræ f. ℥iß
Dein add. sp. etheris nitric. f. ʒj.
Fiat haustus.

Take of copaiba balsam twenty-five minims, mucilage of gum arabic three fluid drachms, let them be rubbed together in a mortar by degrees, pouring on them a fluid ounce and a half of water; then add a fluid drachm of spirit of nitric ether, and make them into a draught.

℞ Uvæ ursi, fol. ʒiij.
Aquæ bullientis Oj.
Fiat Infus.

℞ Infusi istius frigefact. et colat. ℥iß.
Pulv. potassæ nitrat gr. viij.
Fiat haustus.

Take of the leaves of bear berry three drachms, boiling water a pint; let them stand to infuse. Of this infusion cooled and strained take a fluid ounce and half, and mix with it eight grains of powdered nitre, so as to make a draught.

When much pain or irritation connects itself with the discharge, the addition of twenty or thirty minims of the tincture of henbane may be attended with benefit.

It is always necessary, while these astringents and stimulants are employed, to preserve the bowels free by aperient medicines, for the discharge will sometimes be kept up by a constipated state of the intestines.

When this discharge is accompanied by irritation and excoriation it often excites alarm, especially in newly married women, on the score of suspected infection; and it is not seldom that the acrimony accompanying this irritative kind of leucorrhæa is such, that a degree of infection is imparted to the husband, and suspicion, or at the least very uncomfortable feeling, will on this side attach. The physician and surgeon will often be consulted on account of these distressing and delicate occurrences, and he ought to be careful of drawing a hasty inference merely from the circumstance of communication of disorder. The respectability of the consulting parties constitutes for the most part a sufficient guarantee against any thing improper, and, if there be any doubt as to the nature of the discharge, it is often ascertainable whether the disorder be merely fluor albus or venereal gonorrhœa by the absence in the former case of that ardor urinæ which almost invariably attends the latter.

Vomiting of blood (hæmatemesis). Discharges

of blood from the kidney (hæmaturia), and discharge of blood from the bladder (cystirrhagia), are not reckoned among the genera, in the nosology, because they are considered by Cullen as for the most part, if not always, symptomatic.

382. *Vomiting of blood.*

Symptoms.—The connecting symptoms are a sense of weight and uneasiness about the præcordia, which indeed is for the most part some time existent prior to the discharge, and is relieved by the discharge.

Causes.—The discharge is for the most part occasioned by obstructions in the liver, or the spleen, and sometimes is the consequence of suppressed hæmorrhoidal or menstrual flux. Merely constipated bowel will at times produce hæmorrhage from the stomach where there is a constitutional disposition to its occurrence. It is often brought on by blows on the stomach, and sometimes occurs as a consequence of vascular debility engendered by the habits of spirit drinking.

Distinctions.—The blood discharged from the stomach is for the most part much more dark, grumous, and clotted, than that which comes from the pulmonary vessels; it is also usually thrown up in much larger quantities—part of the stomach's contents are not seldom mixed with it, and it produces much more exhaustion at the time than hæmoptysis. It also for the most part takes place in constitutions that have been injured by other disorders, and is preceded as above remarked by præcordial oppression more signally than in the instance of hæmoptysis. (See *Hæmoptysis*).

Prognosis.—It is of a more dangerous nature as to its immediate effect, than hæmorrhage from the lungs; but even here it is rather from the discharge being a manifestation and effect of disordered viscera and broken down stamina, than from the mere quantity of blood thrown up, that a fatal event is to be apprehended.

Treatment.—Whether depletion is to be employed in this disorder depends upon the age and constitution of the patient; and the same remarks apply as in other cases of hæmorrhage. For the most part, however, the habit is too feeble, and the constitution too much shattered to admit of much blood-letting. Purging is almost invariably necessary, and castor oil or Epsom salts should be employed for this purpose. After the bowels have been freely evacuated, astringents may be administered as in hæmorrhages; and in obstinate cases the acetate of lead may be employed. See *Hæmoptysis* and *Menorrhagia.*

383. *Hæmorrhage from the kidneys or bladder.*

Symptoms.—Pain in the loins or above the pubis, and occasionally a difficulty, especially in the first efforts, to discharge the urine.

Causes.—Calculous and other foreign bodies, in the kidneys or bladder, will give rise to the disease; but sometimes the discharge seems to be a sort of plethoric manifestation, the urinary organs being made use of, as it were, by nature, to convey away redundant blood. It sometimes follows violent blows or strains, and is occasionally the result of common inflammation in these very vascular parts.

Distinctions.—The very high-colored urine, occasioned by an admixture of bile, or other disordered states of the kidney or general system, does not stain linen of a red color, as is the case in hæmaturia; nor, in the former instances, is a red coagulum thrown down to the bottom of the vessel.

Prognosis.—When the affection is unaccompanied by any indication of organic disorder, in the parts from which the discharge proceeds, the prognosis may be considered favorable. But these discharges are seldom thus idiopathic, and the degree of danger must be inferred from the degree of the producing derangement.

Treatment.—Saline purgatives, with syrup of poppies, as in the hæmoptysis. If calculus is present, mucilaginous drinks and medicinals will be demanded, such as large draughts of barley water, with tragacanth or acacia gum, mixed in it. Decoction of marsh mallows. The tinctura ferri muriatis, in cases of much weakness, will be found useful. Uva ursi has long had a reputation in urinary discharges.

℞ Uvæ ursi foliorum ℥ß.
Aquæ ferventis Oj.
Fiat infusum.

℞ Hujus infusi frigefacti et colati f. ℥vii.
Pulveris potassæ nitratis ʒj.
Syrupi papaveris f. ℥j.
Fiat mistura. Dosis pars sexta.

Take of bear berry leaves half an ounce, boiling water a pint. Make an infusion; of this infusion take seven fluid ounces, powdered nitre a drachm, syrup of poppy a fluid ounce. Make them into a mixture: the dose is the sixth part.

The peach leaf has been employed with alleged success in obstinate hæmaturia.

℞ Persicariæ foliorum exsiccatorum ℥j.
Aquæ puræ Oij.
Decoque ad Oiß; liquore frigefacto, coletur; bibat æger Oj. in die.

Take of dried peach leaves an ounce, water a quart; boil down to a pint and a half; when the liquor is cold strain it, and let a pint be taken in the course of the day.

Oil of turpentine, in small doses, is occasionally employed in hæmaturia of long standing.

℞ Olei terebinthinæ ♏ xxv.
Mucilaginis acaciæ f. ʒij.
Syrupi papaveris f. ʒj.
Aquæ puræ f. ℥iß.
Fiat haustus: nocte maneque sumendus.

Take of oil of turpentine twenty-five minims, mucilage of gum arabic two fluid drachms, syrup of white poppy one fluid drachm, water a fluid ounce and a half. Make a draught, to be taken night and morning.

384. Order V. Fluxes. Profluvia. Catarrh.—The symptoms of catarrh, or as it is vulgarly called cold, need scarcely be mentioned beyond what are comprised in the definition. The causes are said to be cold and contagion; it is probable, that a degree of contagion connects itself with all catarrhal affection, for you never see one child in a nursery affected by a cold, without the affection reaching the other children of the same family; the difference between the influenza or contagious catarrh of Cullen, and common cold, is probably referrible to the state of the air; and the division should

be into infectious and common, not into contagious and ordinary catarrh.

Prognosis.—Catarrh only, then, becomes dangerous, when it happens to meet with disordered predisposition; thus, that inflammation of the mucous membrane of the nostrils, &c., by which it is constituted, may become protracted and extended down into the bronchial cells, and thus form bronchitis; or it may excite the tubercular latency into action from contiguity and sympathy, and thus come to be productive of true consumption; or it may prove an excitant of asthmatic disposition, or fall into common pulmonary inflammation: but in all these cases the disorder, before it is dangerous, becomes, nosologically, a new affection.

Treatment.—Catarrhal irritation is to be allayed by aperients, diaphoretics, and demulcents, according to the degree of excitement, and accompanying hoarseness or cough.

℞ Potassæ nitratis ℈ß.
Misturæ amygdalæ f. ℥iß.
Syrupi tolutani f. ʒij.
Fiat haustus

Take of nitrate of potass (nitre) half a scruple; almond emulsion a fluid ounce and a half; syrup of tolu two fluid drachms. Make a draught.

℞ Syrupi papaveris f. ʒij.
Spiritus ætheris nitrici f. ʒj.
Mucilaginis acaciæ f. ʒiij.
Aquæ puræ f. ℥iß.
Fiat haustus.

Take of syrup of white poppy two fluid drachms, spirit of nitric ether one fluid drachm, mucilage of acacia three fluid drachms, water a fluid ounce and a half. Make them into a draught.

℞ Pulveris inulæ,
Sulphuris loti,
Pulveris radicis glycyrrhizi, āā ℥ß.
Mellis despumati q. s.
Fiat electuarium: cujus sumat æger cochleariuum unum parvum subinde.

Take of powder of elacampane, of washed sulphur, and of liquorice root, of each half an ounce; honey enough to make an electuary. A tea-spoonful to be taken frequently.

℞ Oxymellis scillæ f. ʒj.
Syrupi papaveris f. ʒiß.
Spiritus ætheris nitrici f. ʒj.
Misturæ ammoniaci,
Aquæ puræ, āā f. ʒvi.
Fiat haustus.

Take of oxymel of squill a fluid drachm, syrup of white poppy a fluid ounce and a half, nitric spirit of ether a fluid drachm, ammoniacal mixture and water of each six fluid drachms. Make a draught.

The last as an expectorant after the inflammatory symptoms have subsided.

385. *Dysentery.* Dysenteria.

Symptoms.—Dysentery sometimes appears, in the first instance, in the form of a purely local disease; and, in that case, the pyrexial symptoms are not manifested till after the griping and tenesmus, and mucous and sanious discharges shall have occurred; sometimes the disease is ushered in by pyrexial irritation, loss of appetite, nausea, flatulency, and frequency of pulse. With the mucous and muco-sanguineous discharges are sometimes passed indurated knotted masses of fæcal matter, called scybala; and the disorder sometimes rises to such a height, or continues for such a length of time, as to produce bearing down of the intestinal membrane; great prostration of strength; falling away of flesh; hiccough; and a fatal termination. At other times the disease will produce chronic affections of the parts implicated, which will last for months, and the patient eventually recover.

Causes.—Every thing which tends to derange the regular functions of the intestinal canal may tend to induce dysentery. It has at times been completely formed from the cretaceous mixture given injudiciously for diarrhœa. Obstructed perspiration, damp air, unwholesome diet, may occasion it; and, like most other disorders, it will prove communicable or contagious, under circumstances fostering such tendency.

Its proximate cause, as pathologists express themselves, is constituted of a mixture of inflammatory action in the villous coat of the large intestine, giving rise to irregular contractions of the gut; locked-up or morbid secretions; and all the consequent disturbance.

Prognosis.—The favorable signs are, a tendency to general diaphoresis; while the urine throws down a sediment, and the stools gradually acquire their natural color and consistence: the unfavorable symptoms are, dryness and contraction, alternated with clamminess of the skin, the pyrexial irritation continuing; the abdomen becoming tense; the tenesmus becoming more urgent; the pulse weak and irregular; the extremities cold, and hiccough and aphthæ making their appearance; while the disease shall become complicated with others, such as ague or hepatic disorders.

Treatment.—The dysentery that is met with in this country does not commonly require the use of the lancet; if, however, the irritation runs up very high, blood-letting, both general and topical, may be occasionally and under due restriction employed; the great objects of treatment are, to get completely rid of the scybala, and to keep under the inflammatory irritation and spasmodic contraction of the colon. An emetic, composed of ipecacuanha and antimony may be premised. Of cathartics, which are indispensable in dysenteric affections, the castor oil is the best; it seems, as it were, made for the complaint; and should be given in half-ounce or ounce doses every day, or twice a day, till the whole scybalous matter is brought away. The oleum lini and tinctura rhei, as recommended for hæmorrhoids, will often be found of service. When refrigerant or saline cathartics are employed (and these seem called for when the marks of inflammatory irritation run high), they should be combined with manna.

℞ Magnesiæ sulphatis ℥iß.
Mannæ ʒiij.
Aquæ menthæ piperitæ ℥ß.
Fiat haustus.

Take of Epsom salts half an ounce, manna three drachms, peppermint-water a fluid ounce and a half. Make them into a draught.

Emollient clysters are occasionally called for, with or without opium, according to circumstances.

℞ Decocti amyli Oj.
Tincturæ opii f. ʒj.
Fiat enema.

Take of decoction of starch a pint, tincture of opium a fluid drachm. Make them into an enema.

To allay irritation, a combination of ipecacuan and opium, as in the pulvis ipecacuanhæ compositus, constitutes one of the best of medicines.

℞ Pulveris ipecacuanhæ compositi gr. vj.
Confectionis aromaticæ q. s.

Fiant pilulæ duæ: ter quaterve in die sumendæ.

Take of compound ipecacuan powder six grains, aromatic confection enough to form two pills: to be taken three or four times a day.

Warm fomentations and stimulant embrocations to the abdomen will sometimes be found serviceable; and it will be expedient occasionally to rub the abdomen all over with castor-oil, as recommended in enteritis, by which, it appears that the expulsion of the scybala will be considerably expedited.

When the hardened fæces are all expelled, and the inflammatory and spasmodic irritation are got under, tonics are called for; and one of the best of these is the calumba, which may be given united to rhubarb.

℞ Infusi calumbi,
Infusi rhei, āā f. ʒvj.
Tincturæ cardamomi compositæ f. ʒj.
Fiat haustus.

Take of infusion of calumba and rhubarb of each six fluid drachms, compound tincture of cardamons a fluid drachm. Make them into a draught.

When opiates are still required, the confectio opii of the Pharmacopœia is one of the best forms in which to administer it.

℞ Confectionis opii gr. xv.
Vini ipecacuanhæ ♏ xv.
Aquæ menthæ piperitæ f. ℥iß.
Fiat haustus.

Take of opiate confection fifteen grains, ipecacuan wine fifteen minims, peppermint water a fluid ounce and a half. Make a draught.

The infusion of cusparia, or simarouba, or cascarilla, may be used in conjunction or alternation with calumba; but, upon the whole, the last mentioned bitter seems the best adapted for that intestinal weakness that has been brought on by protracted bowel disorder. When small points of ulceration have established themselves on the membrane of the intestine, giving rise to purulent discharge, chronic irritation, and hectic wasting, the vegetable narcotics are to be had recourse to, with small quantities of the blue pill. When the liver has had to do with the origin of the disorder, or takes on a decidedly disordered action during its course, mercurials in a large dose will be required; and in all cases we must be careful not to push our tonics, under the notion of debility, while the secretions continue obstinately out of order. The copaiba balsam, combined with one or other, or more than one, of the vegetable narcotics, will occasionally prove advantageous in old dysenteries, connected with a chronically diseased and ulcerated state of the villous coat of the intestine

℞ Extracti hyoscyami,
Extracti conii,
Extracti papaveris, āā gr. xij
Copaibæ f. ʒiß.
Mucilaginis acaciæ f. ℥j.
Aquæ puræ f. ℥v.

Fiat mistura: cujus sumat æger partem sextam bis terve in die.

Take of extract of henbane, of hemlock, and of poppy, of each twelve grains, copaiba balsam a fluid drachm and a half, mucilage of gum arabic a fluid ounce, water five fluid ounces. Make a mixture, of which a sixth part is to be taken two or three times a day.

Rice, barley, Indian arrow root, oatmeal, sago, and animal broths, are the proper articles of diet.

[*Note.*—We have taken the whole of the three last sections from Dr. Uwins's Compendium of Medicine, merely translating the prescriptions.]

CLASS II.—NERVOUS DISEASES. Neuroses.

386. Both in the general introduction to the present article, and as an immediate preliminary to our disquisition on pyrexial, inflammatory, and vascular disorders, we had occasion to make some prefatory remarks, which were applicable to the whole class of diseased affections comprehended under the term pyrexia. Upon the same principle, and with the same view, we now propose to engage in some considerations on the habits and peculiarities of the sentient part of the organisation, in its reference to disordered susceptibilities and deranged conditions.

On this head there is some diversity of opinion, many conceiving that there is a laxity of signification attached to the term nervous, which is inconsistent with the correctness of just pathological principles; while others, on the contrary, imagine that the speculations and inferences of those pathologists, who are always looking for something visible and tangible as explicatory of disease, do not sufficiently recognise the fact, that both ordinary and morbid sensation are directed often by mere functional peculiarities, which must ever elude a further perception than that of the phenomena which they manifest.

It is, we think, pretty evident that a disposition to extremes has shown itself on both sides of the question; and that the functional pathologists, if so we may term them, have often reasoned and deduced with too little recollection, that sentient impulses are intimately connected with vascular states. Indeed Cullen's class neuroses proceeds too much upon inattention to this principle, while, on the other hand, those individuals who will have demonstrative evidence of every pathological occurrence are frequently led by this very laudable feeling—laudable when retained within certain bounds—to infer that there is nothing in medicine worth

attending to, but what the knife of the dissector can open up, or morbid anatomy confirm.

But it is for us, as encyclopædists, rather to select and collate the sentiments of others, than to obtrude our own opinions; and, in consistency with this duty, we think we cannot be better employed than in presenting to our readers, on the present occasion, some pretty long extracts from authors bearing upon the subject now particularly adverted to.

In every part of the study of nature it is common, says Dr. Beddoes, for ancient distinctions to vanish as a greater number of objects become known; and as every object is more completely investigated, the intervals are gradually filled up; and productions, once held the most dissimilar, are seen to gain a degree of affinity by the successive modifications of the particular features of the extremes in the members that fall in to complete the series.

Proofs of this observation may be found in the attempts which have been made to distribute diseases into classes. In these later ages an infinite number of experiments have raised the brain, the spinal marrow, and the nerves connected with these, into a degree of importance which they did not possess in the estimation of ancient physiologists. It has been found that where the nerve going to a limb is cut, tied, or injured, the empire of the will over the limb is destroyed, and applications to it produce no sensation. What more natural, therefore, than to impute loss of motion and sense to an altered state of that portion of the animal structure of which intentional alterations are followed by the same disability to feel and move? Again, pinch, prick, or otherwise irritate a particular nerve, and the muscle into which that nerve passes shall be thrown into irregular action. When the same irregular actions manifest themselves, without the interposition of any experimenter, it is simple and reasonable to infer that the nerve suffers as when irritated on purpose, and that the cause of the diseased or irregular action lies in the nerve. Here, therefore, we have a foundation for a distinct class of diseases. This class gains extension from other phenomena. That compression of the brain which accidents perpetually produce, and which sometimes the want of the skull or bony cover in the human subject has enabled others to effect at pleasure, have demonstrated that a certain condition of this principal member of the nervous system is an indispensable requisite to perception, locomotion, and to the other exertions characteristic of the healthy waking state. The anatomy of the organs of sense, in different states, has proved how essential their nerves are to the proper performance of their offices. If the optic nerve be entire, other parts of the eye may be removed, and vision remain. The apparatus provided for conducting the sonorous vibrations of the air to the auditory nerve may be totally destroyed, and yet sounds may be conveyed through the teeth. But hearing ceases, or is impaired, by any disorganisation of the nerve of hearing. It is in vain that the other parts continue perfect. To these direct proofs it may be added that a vast quantity of nervous substance is appropriated to each sense, and that it is distributed in a manner which always raises admiration when exhibited. The nicety of the organ also corresponds to the apparent care bestowed in the distribution, as is particularly manifest in comparing the interior of the nostrils in animals which differ in acuteness of smell.

These observations give us two additional kinds of complaints, properly to be denominated nervous. When the hearing is impaired, and the auditory nerve altered in its structure, we have nervous deafness; and nervous dimness of sight, or blindness, under similar circumstances of vision and the optic nerve.

From slight numbness up to utter insensibility, and from premature loss of power to total immobility of a part, there are many gradations; but the whole appear to be steps in the same progress. Hence the first comes to be referred to the same head as the last; and in fact corresponding causes, capable of acting on the nerves, are often discovered in the slighter affections. Mineral poisons make the limbs tremulous first, and afterwards motionless. Fear and anger are every day observed to make persons quake all over. They are occasionally observed to bring on perfect palsy. Indeed common language marks the analogy of these affections. One has often been called the shaking, the other the dead palsy.

So far the deduction appears to proceed satisfactorily. We may follow it yet another step without danger of being puzzled. Supposing a complaint in which a considerable part of the symptoms shall be from the first exactly such as some of those above enumerated, and another part of a different nature, and not by any certain experiment or observation referrible to that particular part of the organisation, yet we may venture to term the whole disorder nervous. We do this with more confidence if the symptoms of each description occur together or alternate. Hysterics may be taken as an example. The same hysterical person shall tremble at one moment, and become blind or deaf, or lose the use of a limb, at another. Then a sneezing or retching of the most excessive violence shall supervene. Not only so, but the paralytic limb shall be restored, in the twinkling of an eye, to its full powers upon the commencement of sneezing or retching, upon a fit of laughing or crying, or the rising of a ball in the throat, or upon the occurrence of any other of the symptoms which show themselves in this infinitely diversified complaint. Now, having referred the universal trembling and partial deadness to a certain change in the state of the nerves, we refer to the same constituent parts of the body, the suffocating ball in the throat, the retching, the sneezing, and the other symptoms, though I may not be able to excite them by any operation upon a dissected nerve. But they appear to be intimately connected and interwoven with the others; and indeed seem to make up one disorder, as different strands are twisted into one rope.

But from this point our track becomes more uncertain. By extending the term nervous, upon the strength of one or two circumstances of resemblance, we are in danger of losing all

meaning, and reducing the most heterogeneous affections to one head. It will therefore, if we would keep clear of embarrassment in language, be necessary to have a word entirely new, or some addition to that which we have hitherto retained, in some cases where nervous symptoms occur. For there occur also symptoms of a different character; and as these predominate they require to be marked. In the beginning of small pox for example, and also of some feverish complaints without eruption, there shall be irregular action of the muscles, or convulsions. Along with the convulsions too there shall be other appearances exactly the same as in diseases strictly called nervous. Yet the small-pox passes not either with nosologists, or with those that follow popular language, for a nervous complaint. The reason is obvious: the nervous symptoms do not generally appear; and in hysteria, if there had only been the retching and the ball in the throat, probably it would never have been considered as a proper nervous disease. The strong pulse, heat, and violent affections of the breathing, in bad cases of small-pox are more common, permanent, and dangerous. They would therefore probably give the disease its denomination, and occasion it to be referred to the inflammatory class, did not the pustules offer so striking an appearance and furnish the matter by which it may be propagated.

There are certainly no diseases of whatever name in which the nerves are not affected; and there are probably no nervous diseases in which the other parts (if they can be considered as destitute of nerves) are not affected. But to call only certain complaints nervous may enable the writer to be more concise without being less perspicuous, which is the proper use of general terms. Nervous disorders then may be considered as those in which the limbs move irregularly or without the direction of the will, in which the organs of perception suffer, and the intellectual functions are disturbed; and this in most instances without any preceding or concomitant symptoms of a different nature, either general or partial.

It is not easy, and perhaps not possible, to invent a term which shall point out any one set of disorders to the exclusion of others. But in common life there would be much less confusion, and somewhat fewer mistakes, if the term nervous were not indiscriminately employed, both where there exist, or have existed, symptoms of a different and peculiar nature, and where they do not. A young person in consumption feels herself low, and is hysterical in various ways; she is therefore persuaded that the cough is nervous; that is, she and her friends persuade themselves there is no danger, or that a treatment very different from that likely to answer is requisite. A gouty veteran becomes tremulous throughout his whole frame. Hence he concludes that he labors under opposite or antagonist maladies; and that if the gout should gain the ascendancy it would deliver him from his other enemy. But in the generality of cases, though it be true that the patient is nervous, it would be more exact to consider him as nervous because he has been gouty. He is only secondarily nervous.

According to a vulgar phrase, when such a one is said, and truly said, to have a complaint of the bile, the physician can frequently ascertain to which of the two opposite states the given case belongs. For in some the liver secretes too much bile, in others too little. Perhaps some such opposition may hereafter be discovered in the variety of nervous complaints. The convulsions to which children are so prone, and the loss of power in old age, would appear to arise from contrary states; the one from excess, the other from defect, of nervous energy? But nothing of this kind can be generally established. Our present acquaintance with the subject does not entitle us to divide the family of nervous ailment into two branches, the one positive, and the other negative. In the same day an hysterical person shall be troubled with painful acuteness of hearing, and with deafness, and be in the intermediate or natural state. The limbs shall be palsied one hour, and the next a strong propensity to motion shall impel the invalid to place all the chairs and tables in a circle, and to skip from one to the other till quite out of breath. Poetical effusions shall follow a fit of stupidity, in a person who is neither dull nor brilliant in her ordinary mood.

In all departments of knowledge, the nomenclature must be as the information. Where one is deficient the other will be vague. In medicine it may be for a long time equally easy to object to a general term, and difficult to replace it by another free from just objections.

All diseases, nay every sort of injury, will, on strict consideration, be found to affect the mind. Some difference in the inward state will be correspondent to the slightest external difference. But in many instances the bodily change is so much more permanent and considerable, that this is overlooked. In a pleurisy, the history of the disease, and of its treatment, is thought to be fully comprehended in an account of the pain, of the pulse, of the breathing, of the number of bleedings, and so forth. In this, and other febrile affections, it is deemed sufficient just to note whether delirium occurs, or at most to mark whether it be a delirium of the low or the frantic kind. Again, the parts concerned in many diseases have been so often examined by dissection, that the physician can read the state of the interior as plainly as if the body were a book, the alteration in organs accessible to sense, and the patient's account of his feelings serving him for letters.

In nervous complaints every thing is different. Changes of the organisation, it is true, have been sometimes detected in nervous complaints, but then the same symptoms equally appear when no such changes exist; so that here morbid anatomy is at present of little or no use in pointing out the correspondence between the obvious and hidden workings of the machine. The intellectual faculties bear a considerable part in these mysterious, and often terrific, scenes. The members, long since reduced under perfect obedience to the will, throw off all control. In ruder ages it was a general persuasion that the furious agitations which sometimes take place were still voluntary, but proceeding from the will of a ma-

lignant spirit who had possession of the patient, and managed his members as the master of a puppet-show does those of his diminutive representatives of man. Among the lower ranks of society, some are still haunted by the same pernicious belief. For these irregularities of thought, feeling, and action, which constitute the essential character, if it be possible to assign the essential character of this class of disorders, we cannot hope to account without some insight into the laws of the human mind. What terrors there are inherent in this subject, different people will probably disagree in attempting to determine. But one thing is clear. It is a subject of enquiry equally shunned by the faculty, and by those who are not of the faculty. Yet it is obvious that the investigation of these laws bears exactly the same relation to the diseases in question, as the comparative anatomy of sound and morbid bodies does to many other diseases.'

We shall follow up this extract from Dr. Beddoes, by a long quotation from Dr. George Gregory, which we consider especially valuable, as corroborating and illustrative of the principle with which we started; namely, that it is of importance, in our investigation of those maladies which are distinctly termed nervous, to appreciate duly, but with proper limits, the information which may be obtained from structural investigation. Indeed, we cannot well conceive of a better introduction to particular disquisitions on nervous affections, than that to which we now beg the best attention of our readers.

'There are not perhaps,' says Dr. Gregory, 'in the whole circle of medical science, any diseases offering so many interesting points of research to the speculative physician, as those which derive their character from disturbance of function in the brain and nervous system, independent of the presence of fever. They may be associated together as the diseases of primary neurosis, and they constitute a series which it cannot but be useful to examine, in the first instance, in a general manner. It will be found that they have a common character, and many points of mutual connexion. To explain these will not only be the means of preventing hereafter much needless repetition, but it will serve to impress upon the student the importance of those pathological relations among diseases, which serve equally to improve and to facilitate practice.

The diseases comprised in this series are apoplexy, palsy, epilepsy, mania, chorea, tetanus, hydrophobia, neuralgia; to which may be added syncope, asphyxia, hysteria, and hypochondriasis. Though deriving their character principally from a morbid condition of the nervous system, they are all more or less connected with disturbed function in other parts. The four last mentioned, however, are so intimately connected with disorder in other organs that, in the present division of the work, I shall merely keep them before me with a view to some points in their general pathology, reserving their separate consideration to future parts of the volume.

Physiology teaches that among the several functions of the brain and nerves, of which some are well, and others only imperfectly ascertained, the principal are sensation, voluntary motion, and the manifestation of the mind. It is natural to expect that, from disturbance in them, the chief characters of the neuroses should be derived; and, accordingly, we find that coma, convulsion, and mental aberration, are the three great classes to which we may refer the symptoms of these diseases.

1. Coma consists in the loss of sensation, thought, and voluntary motion. In this state of disease, however, the organs of involuntary motion preserve their functions; and consequently it is by the continuance of the pulse and of the breathing that we distinguish between coma and the states of syncope and asphyxia. But, though in this manner we are enabled to mark the diagnosis between coma and the disordered conditions of body with which it is liable to be confounded, there are two states, consistent with health, from which it cannot be distinguished by such a criterion; I mean the states of sleep and of intoxication. In all cases of suspected coma it is necessary, for the safety of the patient and the credit of the practitioner, that this point should receive attention. If duly kept in view there is no great probability of any error occurring; for it is inattention to the circumstance, and not any difficulty in deciding upon it when once suggested, from which mistakes have originated. Coma is distinguished from sleep by the impossibility of rousing the patient by shaking, noise, or otherwise. The smell of the breath will, for the most part, be sufficient to characterise the state of intoxication; but in extreme cases there will always be difficulty, for actual coma may possibly have supervened. At all times attention should be paid to the circumstances which preceded the attack; for by this means not only will ambiguity be prevented, but the physician will obtain such an insight into the causes of the disease, and the habits of the patient, as will assist materially in directing his practice.

The abolition of sense and voluntary motion then constitutes perfect coma, and it is the distinguishing feature of apoplexy, the first disease which will be noticed in the present series. It remains to state that the loss of these functions is not always complete. Partial deprivations, both of sensation, thought, and voluntary motion, occur in the chronic diseases of the brain, and they afford many of the most prominent symptoms of such disorders. Of this kind are preternatural drowsiness, or lethargy, paralysis of particular muscles, indistinctness of vision, amaurosis. They are all referrible, however, to the general head of coma.

2. The second set of symptoms occurring in the chronic diseases of the encephalon may be classed together under the head of convulsion or spasm. The state of convulsion is commonly defined to be that wherein the voluntary muscles of the body are excited into action by powers independent of the will. It is not, however, peculiar to those muscles. Not unfrequently those of involuntary motion are similarly affected, the diaphragm for instance, and smaller muscles of inspiration, as in asthma, or the muscular coat of the stomach or intestines, as observed in colic. It would appear indeed as if no mus-

cular fibres were exempt from spasmodic contraction, excepting those of the heart.

Of the voluntary muscles of the body it has been remarked that those which are most immediately under the influence of the will, and most frequently employed, are those principally affected in convulsive disorders, and the same observation will be found applicable to paralytic affections. Of this kind are the muscles of the eyes, eyelids, face, arms, and legs. Spasms of these muscles are observed in chorea, hysteria, and all the lighter forms of nervous affection; while spasms of the muscles of the neck, back, and belly, occur in tetanus, hydrophobia, epilepsy, and indicate a severer kind, or more aggravated degree of disease.

Convulsions have been divided into two kinds—the permanent, and that which alternates with relaxation; in other words, the tonic and clonic. Tetanus affords an instance of the one; hysteria of the other. The distinction is of little consequence unless coupled with the pathological principle that the tonic or tetanic spasm is a disease of infinitely more importance than the common or clonic spasm. The former arises from causes over which we have little or no control, and is, at all times, a state of the utmost danger; while the latter is very frequently little more than the evidence of a peculiarly irritable disposition in the nervous system, and may exist, even to a great extent and for a long time, without exciting any uneasiness for the ultimate safety of the patient. In all reasonings, indeed, concerning a disease accompanied with clonic or common spasm, it is necessary to look to the original constitution and temperament of the individual. There exists in some persons an irritable habit of body, a disposition in the system to be excited on slight occasions, and consequently a more than ordinary tendency to spasm. This manifests itself even when any function of the body becomes, from accidental circumstances, disturbed. Such a habit of body has been denominated by some physiologists the nervous temperament. It is characteristic of the infantile period of life, and of the female sex. The distinction between this irritable habit of body and the morbid state of convulsion, though sufficiently apparent in common cases, is yet, on many occasions, a matter of considerable difficulty. In point of fact they will be found to run into each other by insensible degrees, constituting, as we shall afterwards show, one of the many interesting features in the pathology of epilepsy.

Independent of those convulsive actions of the whole body to which the term fits is popularly applied, there are a variety of partial convulsions referrible to this general head, which occur as evidences of chronic disease within the brain. Of this kind are permanent contraction of the iris, irregular contractions of the muscles of the eye, constituting squinting, and the convulsions of the pterygoid muscles, commonly called grinding of the teeth.

3. The symptoms by which chronic disease of the brain manifests itself may be referred, in the third place, to the head of vesania, or mental aberration. Of this disordered condition of the brain physicians have noticed many varieties. It may be either temporary or permanent; that is to say, it may assume the form of delirium or mania. It may be either general or partial; that is to say, the powers of thought may be completely lost, as in the case of idiotcy; or some one faculty of the mind may be disturbed, while others remain perfect, or only partially impaired. Sometimes, for instance, the imagination labors under a strong and unconquerable delusion, while the memory is perhaps still enjoyed in full perfection. This constitutes the highest grade of mental aberration, and is the characteristic feature of mania. At other times the memory fails, while the powers of perception are still uninjured. This is a frequent consequence of severe injuries of the head, and of paralytic seizures. It is a very common attendant also on that morbid change in the structure of the brain, which frequently occurs in the later periods of advanced life.

Aberrations of mind, lastly, vary in their character and intensity. Sometimes they are attended with fierce excitement, violent aversion, and a disposition to commit acts of violence on themselves or those around them. At other times the delusion of mind is accompanied with a sense, hardly less formidable, of melancholy and settled despondency. To the lighter shades of this disordered condition of the mind physicians have commonly applied the term hypochondriacism. Occasionally we find maniacal aberration coupled with a perfect tranquillity and self-content.

After noticing the general character of the diseases usually called nervous, I proceed to enquire into the opinions commonly entertained regarding their pathology and proximate cause. And here it is to be remarked, in the first place, how manifestly a large proportion of such cases are connected with, and therefore probably dependant upon, certain disordered states of the circulating system. That this principle is not of universal application I shall presently have occasion to show; but in the mean time it will be right to point out what those derangements of the circulating system are, which are so closely interwoven in the pathology of nervous diseases.

1. The first of these is chronic inflammation of the substance of the brain, or of its meninges. That this is the true proximate cause of many cases of chronic disease within the encephalon is abundantly proved by the appearances found on dissection; which are depositions of coagulable lymph upon the surface of the brain, thickening of one or more of the membranes, and suppuration. These unquestionable marks of inflammatory action are, however, but rarely met with, in comparison with two others, frequently adduced as evidences of the same state of disease: I mean increased vascularity within the cranium, and serous effusion between the membranes or within the ventricles. These appearances are very common in different diseases, but in none are they so generally met with as in chronic affections of the nervous system. There are few instances, indeed, of any morbid change of structure in the brain existing without them. Pathologists have differed, however, in their estimate of the importance to be attached to them

especially to that of serous effusion. The general opinion appears to be that, though it cannot be assumed as a proof of the existence of actual inflammation within the brain, it must yet be allowed to denote a degree of morbid excitement of the vessels of the brain, not far removed from inflammatory action.

2. The second of the morbid conditions of the circulating system, connected with nervous disease, is simple congestion of blood in the blood-vessels. This may arise either from an extraordinary flow of blood into the arteries of the brain, or from the difficulty experienced in the return of blood to the heart. The peculiar structure of the large venous trunks of the brain is calculated to lead, under certain circumstances, to stagnation, or, as it is now more commonly called, venous congestion in the head. That such a state of the circulating system in the encephalon does occasionally exist there cannot, I presume, be a doubt; but it may be fairly questioned how far we are able to judge of its existence, with any degree of accuracy, by examination made after death. It is at least sufficiently ascertained, that that fulness in the vessels of the brain, so often found upon dissection, and supposed to denote congestion, depends in a great degree on the position in which the body had lain previous to examination.

3. The third of those states of disease to which our attention must be paid in this enquiry, is hæmorrhagy. The rupture of a blood-vessel within the brain acknowledges many of the laws which affect other hæmorrhagies; but the want of outlet for the effused fluid, the peculiar delicacy of the structure of the brain, the importance of its functions, and, above all, the remarkable effects of pressure upon its substance; give to the hæmorrhagia cerebi an interest far superior to what belongs to any other form of hæmorrhagic disease. The symptoms produced by effusion of blood within the brain, are, with few exceptions, those of apoplexy; and the nature and varieties of cerebral hæmorrhagy will accordingly constitute the most important feature in the pathology of that disease.

4. The fourth morbid condition of the circulating system, observed in certain diseases of the nervous kind, is an imperfect supply of blood. The brain, like every other organ of the body, is dependent for the due exercise of its functions on the circulation. It can neither perform them properly when the supply of blood is too great, nor when it is defective. Syncope is the usual result of a want of due supply of blood to the brain; but convulsions occasionally arise from the same cause, as is well exemplified in the instance of puerperal hæmorrhage. It is not often that we have to apply this principle in the pathology of nervous diseases, but in a general view of the subject, such as we are now taking, it would have been improper to omit it.

5. In like manner it becomes necessary to notice a fifth state of the circulating system which is occasionally present in nervous diseases;—I mean the supply of blood imperfectly oxygenated, and therefore unfit for supporting the functions of the nervous system. This principle, it is true, like the last, is very limited in its application, but it enters into the pathology of apoplexy, and is the foundation of many of our reasonings concerning asphyxia.

I have already stated that there are states of disease of the brain independent, as far as we can judge, of the circulating system.

1. The first of these is simple compression. This may arise either from a coagulum of blood, a soft tumor, a bony excrescence, a depressed portion of the skull, or the presence of some foreign body. The effects of pressure vary extremely, according as it takes place suddenly or gradually. In most instances, as already observed, the symptoms occasioned by pressure on the brain partake of the comatose, or apoplectic character; but instances are upon record, particularly in the case of gradual pressure, where such a state has been followed by symptoms, not of insensibility, but of high nervous excitement, by mania and convulsions.

2. There still remains to be stated one principle of very general application in the pathology of nervous disorders. Hitherto we have had some cognisable cause for the symptoms—the effusion of blood, inflammation, or the pressure of a tumor. But it is to be remembered, that there exists an affection of the brain and nerves equally independent of pressure, and of all disturbance in the circulation within the encephalon. The best illustration of this principle is afforded by the phenomena of the narcotic poisons, where coma and convulsion are produced by means which obviously act on the sentient extremities of the nerves, and which, we may fairly presume, deprive the nervous substance of its mobility, or of its power of receiving or communicating impressions. Such a pathological principle is necessarily obscure, from the very nature of the functions concerned, but it will be found an indispensable one on many occasions, as, for instance, in any attempt at explaining the pathology of tetanus and hydrophobia, or in elucidating those varieties of epilepsy and chorea which depend upon the sympathy of the brain with some distant organ. The principle being once established, there remains no longer any difficulty in understanding why, in a great variety of cases of chronic disease of the brain, no morbid appearances of any kind are found upon dissection. This interesting fact, indeed, has been denied by some, and explained away by others; but it is too frequent and too obvious to be thus got rid of. The student in medicine may here receive an important lesson. He may learn from this, that the causes of death are often as obscure as the sources of life and health; and that morbid anatomy, with all its acknowledged advantages may, if pursued too exclusively, injure rather than forward the conclusion of the pathologist.

The observations now offered on the character and general pathology of nervous diseases will tend to point out the very intimate connexion subsisting among them. The same thing will be further illustrated by a view of their predisposing and exciting causes, by a consideration of their mutual conversion, and, lastly, by a survey of the principles of treatment applicable to the greater number of them. But, before adverting

to these topics, I would wish (without, however, going into any detail on the subject) to notice the attempts which have been made to connect particular symptoms observed during life with certain appearances found after death;—in other words, to establish minute diagnosis among the morbid affections of the several structures contained in the encephalon. Pathologists, more especially those of recent times, have been at pains to distinguish inflammation of the arachnoid, from a similar affection of the other membranes;—extravasation into the ventricles from extravasation with laceration of the substance of the brain;—disease of the anterior from disease of the posterior lobes of the brain;—injury of the brain from injury of the medulla oblongata. It would be presumptuous to say that attempts of this kind are altogether nugatory; but it cannot be denied that hitherto very little success has attended them; that the rules laid down by authors are subject to such numerous exceptions as to interfere greatly with their application in practice; and, lastly, that no reasonable hope exists of deriving from them, even if considerably improved, any portion of practical advantage.

It is of more importance to trace the analogies among the chronic diseases of the encephalon than their minute shades of difference; and we shall be assisted in this, in the first place, by considering the similarity, and even, in many cases, the identity of their predisposing and exciting causes. Mania for instance, and epilepsy, are hereditary. The exciting causes of epilepsy are for the most part those also of apoplexy and palsy. Chorea, hysteria, and many varieties of epilepsy, have a common origin in a disordered state of the stomach and bowels. But in no way is the connexion among these diseases so strikingly displayed as in the circumstance of their mutual conversion, and in their manner of running into each other by insensible degrees. I have already alluded to this in the case of hysteria and epilepsy, but it is equally well marked with regard to palsy and apoplexy, syncope and convulsion, convulsion and mania, mania and apoplexy. One individual of a family has had epilepsy, while others have been deranged. Epileptics commonly die with comatose symptoms. Neuralgic affections are not unfrequently succeeded by amaurosis, or by apoplexy. Instances of this important principle in pathology need not be multiplied, as they must be familiar to all who have enjoyed any share of general practice.

It remains only that I notice the principles of treatment applicable to the greater number of the diseases which are now under consideration, and it will be found that the pathological analogies subsisting among them are strikingly confirmed by the effects of the juvantia and lædentia. The depleting and lowering system adapted to the particular circumstances of each patient, and the peculiarities of each disease, are that upon which the physician places his chief reliance; and it is, with some few exceptions, of powerful efficacy in all of them, whether exhibiting the character of coma, of convulsion, or of mental aberration. This is the great principle kept in view, whether we employ bleeding, purging, leeches, cupping, local cold, blisters, issues, and setons; or content ourselves with remedial means of a less formal though not less useful character, such as a cooling spare diet, regular exercise, or a course of aperient mineral waters. By these means, early, steadily, and judiciously applied, we may often do a great deal towards the relief, or permanent cure, of the chronic diseases of the brain; while without them, and depending upon stimulants, and antispasmodics, our expectations will be but too often baffled.'

The reader who shall have attended to the general bearing of the preceding extracts, will learn the importance of endeavouring to distinguish between structural and mere functional change in all inquisitions as to the nature and peculiarities of diseases which seem, in an especial manner, to have to do with those organs which are destined by nature to be the media of perception, sensation, and even intellect. We are now about to present, we were going to say in contrast, an exceedingly instructive outline of the diseases of nerves, from the pen of an individual to whom morbid anatomy and pathology are under the highest obligations. This quotation we shall follow up by some remarks on the peculiarities of nervous disorders, from a MS. course of lectures which now lies by us; introduce some observations on the principal points of distinction between nervous disorders, as they are termed, and other maladies; and then close the whole by a corollary or two of general combination and application. By this plan we shall lessen the necessity of more lengthened detail that we should otherwise enter into on the individual affections of the class.

'The pathology of the nerves,' says Dr. Abercrombie, 'is entirely in its infancy, but the investigation seems to promise very interesting results. From what we already know, there is every reason to believe, that nerves are liable to diseases analogous to the diseases of the brain and of the spinal cord, which may affect them either in their substance or in their membranes, and are probably the source of several diseases which are at present involved in much obscurity.

In as far as this subject has hitherto been investigated, the following may be considered as the principal idiopathic diseases of nerves which have been observed.

1. A uniform dark red color of the nervous substance, occupying a defined space, perhaps an inch or two in extent. This was observed by Martinet (Revue Medicale, Juin, 1814), in the median nerve, in a case in which there had been violent pain of the fore-arm, followed by palsy. Repeated blisters removed the paralytic affection; but, as soon as the blisters healed, pain returned followed by palsy. In a similar affection of the right sciatic nerve, accompanied by palsy of the limb, he found a diseased portion of nerve enveloped in a quantity of gangrenous cellular tissue. In another case he found a diseased portion of the crural nerve, which was an inch and a half in extent, enlarged to about double its natural size. This portion was of a violet red color, and strewed throughout with small ecchymoses each about the size of a pin's head.

2. Serous or bloody effusion within the sheath

of the nerve, penetrating the substance of the nerve, and separating its fibres from each other. This appearance was found by Martinet in the sciatic nerve of a man who died of pneumonia; he had been affected with violent pain in the posterior part of his thigh, aggravated by the least motion so as to make him cry out.

3. Pus effused in the same manner among the fibrils of the nerve. This was found in the sciatic nerve by Martinet, in a man who died of disease, both in the head and the abdomen, and who had been affected during the latter part of his illness with violent pain in the course of the sciatic nerve. The cellular texture surrounding the diseased portion of the nerve was also penetrated by pus. He found the same appearance in a young man who died of consumption, and who had been affected for two months with lancinating pain, and a painful feeling of numbness extending from the ham to the top of the thigh.

4. Ramollissement of the nervous substance. A man mentioned by Descot (Descot sur les Affections Locales des Nerfs), died in the Hotel Dieu, after he had been for six months blind of one eye. The optic nerve was found reduced through half its extent to a liquid matter of a white color.

5. Ulceration of the substance of the nerve was observed by Mr. Swan in connexion with a fungous ulcer in the leg. There had been such violent pain of the whole leg and thigh, as to render amputation necessary, and, in many parts of the limb, the nerves were found very much enlarged. *Swan on the Local Affections of the Nerves.*

6. Small tumors attached to nerves, and productive of violent symptoms, have been described by various writers. In a remarkable case, by Portal, a woman was cured of epilepsy by the removal of one of these tumors from the thumb. The slightest pressure upon it gave great pain, and frequently brought on an epileptic attack. The removal of such a tumor however from one of the auxiliary nerves by Sir Everard Home, terminated fatally; and the safer mode of treating such affections appears to be to remove the portion of nerve entirely to which the tumor is attached, when the nerve is so situated as to render such an operation advisable. Small tumors or tubercles have also been found on internal nerves. Sedillot found one in the optic nerve, in a case of amaurosis; and Berard has described a black tumor as hard as scirrhus developed in the substance of the diaphragmatic nerve. The man had been asthmatic, but he had also slight emphysema of the lungs.

These tumors are generally very small; but there is another species of tumor which grows to a considerable size. One mentioned by Mr. Pring (Pring on the Nervous System), the size of a pigeon's egg, was cut out from the arm, by dividing the nerve above and below. On cutting into it an expansion of the substance of the nerve seemed to form an imperfect cyst, which contained a medullary and fatty matter, and the filaments of the nerve were continued over it. There had been great numbness and loss of power of the arm, but it gradually improved after the operation.

7. Nerves have been found both very much enlarged and very much diminished in size; and they have been in a few instances found with the nervous substance destroyed, the membrane at the part forming an empty canal. But these points have not yet been sufficiently investigated.

Few opportunities have as yet occurred of ascertaining the condition of the nerve in those interesting cases of local paralysis, which have been so beautifully illustrated by Mr. Charles Bell, and his lamented friend the late Mr. Shaw. It is probable that there is either an inflammatory action in the nerve itself, or its coverings; or that the nerve is affected by disease of some of the parts through which it passes. The only case in which I have had an opportunity of examining the parts, since I was acquainted with the discoveries of Mr. Bell, was lately, in a woman about forty years of age, who died of organic disease of the stomach. About a fortnight before her death, she was seized with twisting of the mouth and paralysis of the orbicularis of the left eye. She had afterwards considerable indistinctness of speech, and, before her death, there was inflammation of the left eye, with an evident tendency to sloughing of the cornea. A small hard tumor was felt under the ear, deeply seated betwixt the angle of the jaw and the mastoid process. On dissection no disease could be discovered in the brain. The tumor under the ear was found to be the size of a small bean, very firm, of an ash color; and, when cut across, it discharged thin puriform sanious fluid from minute cells in its substance; it lay directly above the facial branch of the portio dura; and there was considerable appearance of inflammation in the cellular structure surrounding the nerve; but I could not discover any deviation from the healthy structure in the nerve itself. I thought it was diminished in size at the place where the tumor lay over it, but in this I might be mistaken. In a case by Descot, connected with extensive suppuration and caries of the auditory portion of the temporal bone, a part of the portio dura was entirely destroyed; and in a case by Billard, connected with an unhealthy abscess of the parotid gland, the course of several of the nervous branches was interrupted by destruction of part of their substance. An epileptic patient, mentioned by Serres, had inflammation followed by opacity of the right eye, loss of feeling of the conjunctiva, and insensibility of the right nostril, and right side of the tongue. He died of an affection of the brain; and, on inspection, the fifth pair of nerves, at its origin, was found yellow, softened, and reduced to a state almost gelatinous.

To this source, diseases of the nerves, also, are referred certain severe and obscure affections of the nervous kind, some of which have supervened upon slight injuries, and others come on without any obvious cause. A young lady, mentioned by M. Verpinet, received a slight wound with the point of a sword on the inferior and outer part of the fore-arm It very soon healed, but most violent pain continued in the fore-arm, wrist, and hand, accompanied by convulsive motions of the arm, and loss of the voluntary power of the wrist and fingers. The affection resisted every mode of treatment for two years, and then got speedily well after the

application of the actual cautery to the cicatrix of the original wound. In a lady, mentioned by Mr. Swan (Jour. de Med. vol. x), a slight wound on the thumb was followed by numbness, pain, convulsive motions of the arm, and spasms, which occasionally affected the opposite arm, and sometimes the whole body. In this case the affection seemed gradually to wear itself out, though she was not entirely free from uneasiness at the end of seven years. A very violent case of the same kind, described by Mr. Wardrop, (Med. Chir. Trans. vol. viii.), was cured after twelve months by amputation of the finger. In a similar case by Larry, which followed a wound, a portion of the nerve was removed, without complete success, though the disease was very much alleviated. In a singular case by Sir Everard Home (Phil. Trans. 1801), a gentleman received a violent sprain of his thumb, by the weight of his body being thrown upon it, in saving himself when nearly thrown off, by a sudden motion of his horse. He was afterwards liable to paroxysms, in which his thumb was first bent in towards the palm of his hand; a spasm then took place in the muscles of the arm, after which he became insensible, and continued so for about a quarter of an hour. The attacks returned frequently in the arm, but it was found that the pressure of a tourniquet prevented the insensibility. A nerve in this case was divided without success. The tourniquet lost its effect in arresting the spasms, and he died suddenly after three months, but there was no examination of the body.

In the Medical and Physical Journal, Mr. Jeffries has described a remarkable case of a violent neuralgia of the face, which was cured by the extraction of a small fragment of china, which had been lodging there for fourteen years; and M. Descot mentions a case in which a very severe affection of ten years standing was removed by the extraction of a carious tooth. A young lady, mentioned by Mr. Pearson, was seized, without any obvious cause, with pain in the thumb, accompanied by a morbid sensibility of the part; the affection gradually spread over the arm, and was accompanied by loss of nearly the whole muscular power of the extremity, with morbid sensibility of the integuments, and a strong contraction of the fingers, so that the points of the nails were forcibly pressed against the palm of the hand. The fingers were not under the control of the will, and every attempt made to extend them was accompanied by insupportable pain. The joint of the elbow also was contracted, and voluntary motion was nearly lost over the whole extremity. It was also very much diminished in size, while the morbid sensibility of it was inexpressibly distressing. After some time the other arm was slightly affected in the same manner, and she had likewise pain and great debility of both the lower extremities. After this affection had continued about a year, it got well under the use of a liniment composed of olive-oil, turpentine, and sulphuric acid. This produced most severe erysipelatous inflammation, which, beginning upon the affected arm, extended afterwards over the whole body. (Med. Chirurg. Trans. vol. viii.)

Little has hitherto been done on this curious and interesting subject, but it certainly promises most important results, when it shall be more extensively cultivated. For we have every reason to believe that both the nerves themselves, and the investing membrane, are liable to affections which may be the source of many obscure diseases. It is now upwards of fifteen years since I first saw a girl, aged at that time about eighteen months, and previously enjoying excellent health. She had been left for some time sitting upon damp grass, and was immediately seized with fever, accompanied by such a degree of oppression as led to an apprehension of an affection of the brain. These symptoms, however, passed off in a few days, and, upon her recovery from them, it was found that she was entirely paralytic in the right lower extremity. She has from that time enjoyed uninterrupted health, and is now a big and strong young woman, but the right lower extremity has continued entirely paralytic. It is also a great deal smaller than the opposite extremity, and several inches shorter. All the joints are remarkably relaxed, and the muscles flaccid; but there is no other appearance of disease in any part of it, or in the spine. Very lately I was consulted about a young man, aged fourteen, who had nearly lost the muscular power of the upper part of both his arms, accompanied by a most remarkable diminution of substance of the principal muscles. The deltoid and biceps are reduced to the appearance of mere membranes, and the same affection extends in rather a less degree to the muscles upon the scapula; the muscles upon the fore-arm, however, are full and vigorous. No disease can be discovered about the spine, and in other respects he is in perfect health. The affection has come on gradually, and cannot be traced to any cause.

It is impossible, I think, to explain such cases as these, except upon the principle of local affections of nerves, which are at present involved in much obscurity. There are various other affections which can only be referred to the same subject, and which present some very singular phenomena, though the facts relating to them have not yet been brought together in any connected form. Some time ago I was consulted about a singular disease of this nature, which occurs in paroxysms, and affects in the same manner two individuals of one family, a young lady of twenty-five, and a young man of twenty-two. The lady describes the attack in the following manner. She is first affected with blindness of the right eye, which comes on gradually as if a cloud passed slowly over the eye; about a quarter of an hour after this she feels a numbness of the little finger of the right hand, beginning at the point of it, and extending very gradually over the whole hand and arm, producing a complete loss of sensibility of the parts, but without any loss of the power of motion. The feeling of numbness then extends to the right side of the head, and from this it seems to spread downwards towards the stomach. When it reaches the side of the head she becomes oppressed and partially confused, answers questions slowly and confusedly, and her speech is con-

siderably affected; when it reaches the stomach she sometimes vomits. The feeling of numbness then begins to subside, and, as it goes off, she is seized with violent headach, which continues for several hours, and leaves her for a day or two feeble and languid. The progress of the feeling of numbness, from the little finger to the stomach, sometimes occupies several hours, and the common duration of the whole paroxysm is about twenty-four hours. The frequency of its occurrence varies from a few days to several months; she has been liable to it for several years, but in, the intervals betwixt the attacks, she enjoys perfect health. Her brother, who is twenty-two years of age, is affected almost exactly in the same manner, and he has been liable to the paroxysms for many years. He is a banker's clerk, and in the intervals between the attacks enjoys perfect health. When he feels the commencement of the attack, he hastily brings to a conclusion any business in which he happens to be engaged,—gives distinct instructions to another of the clerks in regard to the state in which he leaves the affairs of his department; then walks home, goes to bed, and soon after becomes insensible. Next day he is in his usual health, except a considerable degree of languor.

These singular cases are under the care of Dr. Gibson of Montrose, and in a letter, received from him as these sheets were going to press, he informs me that they are considerably improved. He thinks they have both derived benefit from a course of purgatives, followed by a course of sulphate of quinine, combined with small quantities of rhubarb. Dr. Gibson adds, that another of the family, a stout young man of twenty, has lately had several attacks of a similar affection, though in a slighter degree.

The affections of internal nerves present a subject of still greater difficulty, and the observations that have been made in regard to them are at present far from being satisfactory. Lobstein (De Nervi Sympathetici Fabrica, usu, et Morbis) thinks he has ascertained the existence of inflammation of the great sympathetic nerve; and to this source he refers many obscure diseases, such as violent hysterical affections, sympathetic affections of the heart, spasmodic cough, colica pictonum, angina pectoris, and many obscure affections of the stomach and bowels. In the same manner he explains the fatal effects which are produced by blows upon the stomach, and the severe symptoms, both in the head and in the general system, which often arise from worms, and from other disorders of the bowels. In a lady who died of urgent vomiting, with burning pain in the spine and on the right hypochondrium, he found the semilunar ganglion in a state of intense inflammation, and the lower part of it livid. In a boy who died with great oppression of the chest, and distension of the epigastrium, supervening upon the retrogression of a miliary eruption, he found deep inflammation of a part of the trunk of the left intercostal nerve, and of the ninth and tenth thoracic ganglia.

These speculations must be received with much caution, especially as nothing is more precarious than morbid appearances, consisting of mere change of color of parts, without any of the actual results or terminations of inflammation. We must forbear to speculate where we have not facts before us, but it appears extremely probable that there are diseases of internal nerves which may be the source of important morbid phenomena. Descot exposed the par vagum upon the neck of a dog, and bruised it on both sides slightly with a pair of pincers; the wound healed favorably, but the animal was affected with general tremors, difficult and laborious breathing, vomiting, great debility and wasting. The vomiting subsided, and the other symptoms were diminished, but he had not recovered a natural state of his breathing, when he was killed at the end of three weeks. The internal organs were all healthy. The nerve on the left side, where the injury had been inflicted, appeared slightly increased in size, and was of a yellowish color; and that on the right side appeared more decidedly enlarged, highly injected, and adhering to the neighbouring parts.'

The following is the extract from the MS. lecture, to which we have above referred:—

It has been said that the rationale of nervous agency is in some sort a matter more out of the reach of our perceptive powers than that of the blood's circulation; or of the assimilation of dead to living, or organic particles. In disturbed or deranged functions, implicating this portion of the frame, there will of course be found a corresponding difficulty attendant upon their divination. We see an inflamed part of it is on the surface of the body, and we know that it consists of a disordered action of the circulatory powers—at least we know that such disordered action is present. In like manner, we can perceive the tumefaction of a diseased lymphatic gland; but a limb or an organ will oftentimes be deprived of its loco-motive, or perceptive susceptibility, without the eye of the observer, or even the knife of the dissector, being able to detect any difference in the organisation from that of health. When, then, we say a malady is nervous, we imply that the faculty of perception is especially implicated, and, knowing that the nerves are the media of that faculty, we infer that these are its seat and source.

But we are naturally discontented with mere inference, and are anxious for demonstration: and this anxiety has seemed to me occasionally to have introduced into pathology, especially into the pathology of the present day, a somewhat erroneous notion in respect to the origin of some disordered states. Many of us seem hardly disposed to allow that any purely nervous derangement can have place, and are ready to accuse either the vascular organs, or the first passages, with being the occasion of the present mischief, when neither the one nor the other has had to do with producing the state in question; for, however difficult the explanation of the fact, fact it seems to be, that independently of the blood-vessels—that independently of the assimilating organs—that independently of the digestive processes, the nerves may be brought into a condition of morbid being, occasioning an irregularity in feeling and function, which may be named, in strict propriety, a nervous ailment.

True it is that, in consequence of the intimate

connexion in structure and office which one part of the body has with another, an affection of the sentient organisation is very often soon followed by vascular and other disturbance; but, even in that case, the blood-vessels are not the only part to be regarded, either in our estimate of the nature of the disorder, or in the institution of our curative means; it is ever indeed of prime importance to ascertain, as nearly as possible, what share a disordered state of the nerves has had in the production of a disordered state of the circulation. But I am now to speak generally of more strictly nervous derangements.

We may first notice a very curious fact—viz. the loss or suspension of the ordinary perceptive faculty, while every voluntary muscle remains obedient to the mandates of the will. Dr. Haslam has given us an account of a patient, a female, having dreadfully mangled her jaw, by a piece of glass, in an ineffectual attempt to commit suicide, and being without any sensation of pain during the whole process. Dr. Heberden, too, speaks of an individual, who, under the influence of some temporary impression, cut away the whole of his testicle and penis, and who afterwards stated that he had not the smallest recollection of feeling any pain from the process; and how often do we see instances of religious or political enthusiasm absorbing the faculty to such a degree, that inflictions of the most violent kind are borne almost without perception.

'Perhaps,' says an eloquent writer, 'no combination of affections could be feigned, which cannot be matched in faithful medical reports, and the reality exceeds whatever the most fertile fancy could invent in readiness to be affected, in violence, in the whimsical manner in which the symptoms are grouped, and in the rapid changes from one state to another. In this last respect, what is fabled in romances and masks, concerning the power of the enchanter's rods, to induce in a moment the stiffness of a statue, or to restore the spell-bound person to motion, is much exceeded in nature; and it is possible that fiction took the hint from this species of reality, since it always must borrow from one species of reality or another. That the dropping of a hair-pin on the floor should make a person start from her seat, and fix her in a preternatural posture, by occasioning preternatural fixed contractions and relaxations equally preternatural, till she sink into insensibility, from which she awakes into vehement delirium, is hardly credible to those who are conversant only with the healthy, and the sorts of sickness to which the robust are subject.

'On comparing an individual, liable to these sad varieties of being, to the engineer who stands unmoved amid the thunder of a battery, to the seaman who maintains his footing upon the deck or ropes of his vessel, reeling under the shock of the elements, or to the Indian who exhibits the signs, and probably feels the throb of intense delight while the flames are preying upon his flesh, how astonishing do we find the range of human susceptibility to the effects of the powers by which we are surrounded!'

Indeed, almost numberless instances might be adduced, both from modern and ancient authors, bearing upon this point; but it is the fact alone about which we are interested. Now this peculiarity is in a greater or minor degree characteristic of a great many nervous complaints, variously delineated in nosological systems; and there are no persons who at all times have exactly the same measure of local insensibility; the shades varying in degree ad infinitum, without the anatomist being able to state any variety in structure or organisation, upon which the variation had depended, and without there being apparently a particle more or less of blood in the vessels of the part than under circumstances of health.

On the other hand we find in some cases an acuteness of feeling in one part or organ, which is totally inexplicable by any à priori reasoning, or anatomical peculiarities. Haslam (to give one example) speaks of a man in Bedlam who was so sane and rational in all his deportment that he was on the point of being dismissed; but he was detained in consequence of having communicated to Dr. Haslam a secret of importance. 'Never,' says the man, 'venture to walk in a certain apartment, for there is a subterraneous fire under that room which communicates such a heat to the floor that I never walk there without having my feet burnt.' Now in this case there must have been an actual perception of pain in the feet from some unknown condition of the brain and nerves; a condition upon which no light is thrown by any reference to the state, at the time, of the vascular actions; and if we talk of mental peculiarities we are equally gratuitous in our explanatory phraseology—since we know nothing of the manifestations of mind but through the medium of the physical frame.

Another very remarkable affection, to which the sentient organs are obnoxious, consists in the existence of perception to a very acute degree without the power of expressing to by-standers that such perception is present. This constitutes that state which is vulgarly named a trance, and may be looked upon as merely a more than common measure of that affection to which we are all liable, as when we are susceptible of a greater than ordinary difficulty in conveying to others or embodying in language the thoughts and feelings which pass in our own minds, nay our own case. Again, one whole order of perceptions shall be abolished, or for a time suspended, while other functions shall be exercised with even more than accustomed facility; an extreme extent of which state is exemplified in the phenomena of somnambulism or sleep-walking, while in all these varieties of being the arterial pulsations shall not undergo any appreciable change, proving to a demonstration that it is the nervous and not the vascular organisation that has been the especial residence of those peculiarities, whence the alterations have originated.

These facts, with volumes of others that might be adduced, of a similar kind, ought, in my mind, to teach us two lessons. They ought to instruct us in the inefficiency of that pathology and practice, which should be regulated upon no other principles than that of vascular irritation or con-

gestion in blood-vessels; and they ought moreover to keep us constantly alive to the remarkable subordination of the physical to the mental part of the frame. A fact and principle in medical experience and theory which it seems to me we are occasionally at least too much inclined insufficiently to appreciate. If it were nothing but the importance which the knowledge and attention now adverted to would teach of manner in the practice of medicine, that itself in its application would be found of no mean moment. I should, I hope, be one of the last to recommend hypocritical charlatanism, and assumption of superior powers; but when we find that the assumption itself has an effective influence, it ceases to be a dishonorable or immoral act. If then we wish for success, in the administration of medicine, let us in prescribing it be careful to join a mildness of manner, with a confident deportment. This is not as I have said to assume a virtue which we have not, but lawfully to act upon the susceptibility of our patients towards assisting by every means in our power their restoration to health.

While I am upon this head it may not be improper to state a single example of the influence of imagination upon the actual physical condition, which is furnished us by Dr. Haygarth in the pamphlet which he published on the subject of the Pretensions of the Metallic Tractors; in order to show that we might even admit all that these pieces of metal laid claim to in respect of actual effect, and yet notwithstanding maintain the fallacy of their claims to any actual virtue in and of themselves.

It is necessary to premise that, in the trials which Dr. Haygarth records, pieces of stick and iron were employed while the patients invariably supposed themselves to be under the influence of the genuine metallic tractors. The case which I have selected was transmitted to Dr. Haygarth by Mr. Smith of the Bristol infirmary, a man of unquestionable credit and veracity. 'Edmund Williams,' says Mr. S., 'applied to me with an obstinate affection of the urinary organs (stillicidium urinæ). The man was a poor feeble subject, and appeared to be impressed with the idea that he should never recover, that nothing would be of service to him, but he was willing to try every thing. In one minute after the points of the wooden tractors had been drawn in various directions about the pelvis, he said I begin to feel something jumping in my inside, and in three minutes and a half the determination of blood to the capillary vessels of the skin was evident, giving him the sensation of warmth to which he had been long a stranger. On the 27th he reported that his hips had been unusually comfortable and warm: this induced me to persevere, especially as the patient himself had become less sceptical as to the powers of the tractors. The gentleman who assisted me having borrowed the pieces of stick I was obliged to make use of two-penny nails, which had before been used on a similar occasion: these were disguised with red sealing wax, and on this account had the dignified appellation of rouge et noir. In fact it was often necessary to play the part of a necromancer, to describe circles, squares, triangles, and half the figures of geometry upon the part affected, with the small ends of our feigned tractors. During all this time we conversed in the patient's hearing upon the wonderful discoveries of Franklin and Galvani, laying much stress upon the power of metallic points attracting even lightning, and conveying it to the earth harmless. To a more curious farce I never was witness; we were almost afraid to look each other in the face, lest an involuntary laugh should remove the mask from our countenance and dispel the charm. But to return to my patient. In one minute he felt 'a smarting in his loins and warmth of the skin;' in two 'heat increased;' in four the operation ceased when he said the 'skin was very warm:' a bystander asked him if he thought himself mended? he replied, 'He would soon answer his question,' and upon sitting down suddenly exclaimed 'yes, I am better.' It was demanded 'how he knew it?' 'When I used to sit down,' he replied, there was always a spirt of water thrown from me, but now I can prevent it.' The experiment was two or three times repeated, and with the same result: in fact the patient absolutely regained the power of retention in a great measure afterwards.'

On this case the reporter of it makes the following reflections.

It may be asked what physical alteration could so suddenly have taken place in the muscular fibres of the sphincter of the bladder, that, from a state of pallid relaxation, they should again be endowed with the power of performing their office. Permit me in my turn to ask the enquirer what is the primary cause of the purple blush which instantly overspreads the cheek of the guilty when accused? Would it be answered because the vessels are distended suddenly with blood; that will be readily granted as the remote cause, but it is the power which directed that operation which I wish to be demonstrated. We shall be equally involved in the same dilemma, but, the facts being admitted, our inability to account for them signifies nothing.

Such cases as this lead to more important inferences when properly appreciated than that for which the experiments were principally instituted, namely, the detection and derision of a gross system of quackery; they are mainly to be valued in the use that may be made of them in regular aud legitimate and conscientious endeavours to restore health; they serve to evidence that very important principle in the theory of living actions—that mental stimuli are by no means limited in their operation to the sentient organisation and faculties; but that they display an agency decided and demonstrative, upon even the minutest fibre entering into the composition of an animal body.

'It is worthy of observation,' says Dr. Cogan, who has written on the Passions, 'that, in every powerful exertion of the imagination, some change takes place in the body corresponding with its nature. In a keen appetite, upon the thoughts of some favorite viand, the salivary glands are stimulated to a secretion of saliva as preparatory to deglutition. We feel ourselves firm, collected, elevated, upon the timely representation of the firm heroic conduct of others. The blood thrills in our veins, and the skin corrugates

at the description of any thing peculiarly horrible; and, under the strong impression of fictitious danger, the attitude of our bodies attempts to evade it. Full confidence in the mystic power of another places the whole system in a situation most favorable to the effects, which the object of his confidence undertakes to produce. This will explain much of what is real in the pretensions of magnetisers, and the exaggerating disposition of both operator and patient will serve to explain the rest.

I have thus, continues the lecturer, guided by the order of my subject, called your attention to the influence of mental impression in aiding and regulating the agency of physical powers, not with a view to make you contemn, but, on the contrary, for the purpose of inducing you duly to appreciate and properly to apply the virtues of medicine in the cure of diseases.

This fact of mental agency upon physical conditions and powers, while it gives us a clue, as we have seen, to the success of unprincipled pretenders to nostrums, directs us as far as we are permitted by a sense of rectitude of conduct and manliness of character to make the best use of that faith which the subjects of our care are ready to repose in our skill; and confers a dignity and importance on the medical profession beyond that which could be claimed from a mere routine acquaintance with drugs and antidotes.'

It will be hardly necessary to say in addition to the above extracts, and the intimations we have already dispersed among them, for what purpose we have thus collated and compared the sentiments and statements of different authors in respect to the pathology of the nervous organisation. We wish to impress upon the mind of the medical student, while it is his duty to seek every opportunity of investigating morbid structure in connexion with morbid action, that such is the nature of the organised body, and such its connexion with external circumstances, that a great deal goes on in the interior of the frame, of which no possible explanation will ever be given if we wait until the knife of the morbid anatomist unfolds the secret. We wish it further to be understood, that the alteration of structure, which post mortem examination unfolds, is often rather the effect than the cause of the malady which has terminated life; or that, even if such alteration or structural disorder has been the means of severing the thread by which existence is sustained, previously disordered workings of a general kind, and not merely the topical malady, have been in point of fact the main and radical source of the incidental derangement of structure. But on the other hand let us always be alive to the probability of mere topical lesion being equal to the production of an immensity of constitutional derangement; and let us feel grateful to such pathological patience and discernment as that evinced by Dr. Abercrombie, in his endeavours to place medicine as much as possible upon the footing of a demonstrative science.

We now proceed to consider the several genera included by Cullen in his class neuroses.

387. Order 1. Comatose Affections. Comata.—On this order we need add nothing to the remarks which have been submitted on the pathology of nervous affection, of its occasional, and indeed most frequent, connexion with the brain, and on the question of pressure upon or other disordered condition of the encephalon inducing the comatose state. See the remarks just made on the class, and those on the nosology in the third division of the present article.

388. *Apoplexy.*

Symptoms.—The patient in the most common form of apoplexy falls down as with a sudden stroke, which the name imports; he is deprived of sense and motion, unconscious of every thing that passes around him, and as if in a deep sleep, for the most part making a stertorous noise. While sense and motion are thus suspended, the heart and arteries, as noticed in the definition, continue to carry on the circulation. It is not, however, invariably that this apoplectic seizure is thus so sudden or so complete. Sometimes it is preceded by violent pains in the head, sickness of stomach, dimness of sight, paleness of face, vertigo and loss of recollection; this state lasting for some time, at length complete coma supervenes, and the patient becomes equally unconscious as when the attack is more sudden. Sometimes a palsy of one side precedes the coma, and the apoplexy seems to proceed from the palsy, as the palsy in other cases follows the apoplexy.

In which ever way the apoplectic fit commences, there are certain appearances presented during its continuance which merit attention. The pulse at first is commonly small and irregular; but, as the system recovers from the shock, the pulse becomes full and strong, and is generally slower than natural. Respiration is much embarrassed, being always slow and occasionally irregular. In all the severer degrees of the disease, this laborious breathing is accompanied by stupor; and a frequent appearance is that of foam or frothy saliva excreted from the mouth and blown away from the lips with considerable force.

The skin is commonly warm and bathed in a copious perspiration. In the worst cases of the disease a cold clammy sweat has been observed. The face is generally pale, the cornea dull and glassy, and the pupils permanently dilated. The teeth are closely clenched, and the power of swallowing, though seldom wholly lost, is for the most part so much impeded as to oppose the most serious obstacles to the administration of remedies. The bowels are torpid, as is usual in all cases of cerebral oppression, and they resist the action even of powerful cathartics. If blood is drawn from the arm the coagulum is commonly firm, and Sir Gilbert Blane has noticed that it is in most instances covered with the inflammatory crust.

The duration of the apoplectic fit varies from two or three hours to as many days. Thirty hours Dr. Gregory (from whom we principally extract this very correct history) states to be the average duration of those which have fallen under his own observation. Instances indeed are on record of sudden death from apoplexy; but in many of these cases there is reason to suspect that the immediate cause of death was

rather to be found in some affection of the heart, or large blood-vessels in its neighbourhood, than in injury to the brain.

It should be observed that the full paroxysm is occasionally ushered in by premonitory symptoms of more gradual occurrence and permanent character than those above mentioned. There will be vertiginous sensation, loss of memory, the perception of black spots floating before the eyes, faltering in speech, more than usual drowsiness, and indisposition to take an interest in the common affairs of life, and in fine all the indications of cerebral disturbance for some length of time. The most usual times of apoplexy's occurrence is between the age of forty and sixty; the most common times of the year are in the spring or fall, when atmospheric temperature is subject to sudden variations.

Causes.—Certain conformations of the body are considered as predisposing to apoplexy. The apoplectic make, consisting of a short neck, large head, and florid complexion, is proverbial; though some have questioned whether individuals thus constructed and circumstanced are more obnoxious to the complaint than others. Habits of life may increase the tendency to apoplexy without always proving the actual excitants of the malady. These are, full living, the indulgence of wine, sleeping after dinner, and lying in bed in the morning longer than is proper; mental anxiety, intense thought, carelessness as to the alvine evacuations, neglect of exercise, and indulgence in venery.

The principal exciting causes of apoplexy are, the immoderate use of wine and spirits; exposure to cold, so as to check the perspiration; violent exertion of body or mind; very long or loud speaking, especially if much mental exercise accompany it; gout, rheumatism, and cutaneous disorders, translated from the extremities or surface; severe fits of coughing; stooping the body; exposure to hot suns, producing apoplexy in the way of coup de soleil; warm bathing injudiciously used; and the inhalation of poisonous vapors. In respect, however, to the first mentioned sources, there is reason to doubt whether, when they affect the frame violently, and even to the production of death, the effect is not for the most part of a different character from that of the apoplectic seizure.

In respect to the proximate cause of apoplexy, as pathologists sometimes express themselves, or that state of brain which is necessary to the actual induction of the fit, we shall find in this, as in most other affections, that it is various. Intimations on this head have already been thrown out; and we may here repeat, that, although some contend for the necessity of absolute hæmorrhage upon the brain, or at the least for effusion, to produce genuine apoplexy, it should appear that there are several conditions of the cerebral system which at different times constitute the immediate cause, or the actual circumstance of the disorder. Slow inflammation of the membranes; mere temporary fulness of vessel; gradual loss of power in the nervous system, and in the brain, especially as the main portion of the nervous mass; ossification, or other obstructions to some of the vessels, causing too little blood on one part of the brain and too much on another; these, and probably other circumstances and conditions, may occasionally prove quite equal to the production of the apoplectic state. The old division of apoplexy was into sanguineous and serous; the one being constituted of actual blood poured out from vessels, the other of the extravasation of serum. Another division has been suggested of cerebral and meningeal the one consisting in hæmorrhagia cerebri, and always attended or followed by palsy; the other existing in the membranes, not in the substance of the encephalon, and not being accompanied by paralysis. It may be observed of all these distinctions that there does seem some foundation for them, but that none of them are tenable in the abstract way which systematists have assumed them to be. Of one thing we may generally feel pretty certain, that if with a decided attack of apoplexy there is a decided loss in the power of one limb, or one side, a rupture of blood-vessels, or at least a pouring out of either actual blood or serum upon the brain, has been the occasion of the symptoms. And here we may remark, in connexion with the proximate cause of apoplexy, that the circumstances are generally illustrative of the decussation of the nervous system: at what particular part this crossing or interchange of nervous fibres takes place does not seem to be quite a settled point among pathologists; but that it does obtain is rendered evident even by the phenomena of an apoplectic seizure, or a blow upon the head; the resulting paralysis being on the side opposite to the part of the brain in which the lesion is made. It is, however, a curious fact, that this, though a general, is not an invariable occurrence: now and then the injury, or hæmorrhage, or lesion, of whatever kind, and the consequent palsy, are on the same side; which increases the difficulty and perplexity that still accompany all investigations on the subject of encephalic lesion for the purpose of throwing light on the function of the brain as connected with its structure. On a subject which is so exceedingly obscure we ought to receive with great commendation the exertions of industry directed to this point of pathology; which, if they do no other good, are at least calculated to prevent that hasty and erroneous generalisation, with respect to structural function, to which some physiologists have on the other hand proved themselves too prone.

Distinctions.—Was the complaint of which the patient died apoplexy, or epilepsy, or intoxication, or other disorder of the brain? is often a question proposed by curiosity, and sometimes in the course of judicial inquisition. These distinctions are sometimes not very easily traced; indeed one state of the brain often falls into another, and systematic nomenclature, we wish again and again to urge, often assumes a precision which does not obtain in fact. From epilepsy, however, we may generally say, apoplexy is distinguishable by the absence in the latter complaint of that foaming at the mouth and convulsions which characterise the epileptic paroxysm; a secretion of saliva does indeed, as we have above remarked, occasionally attend upon the apoplectic fit, but it is puffed out with the

respiration in a different way from that which is seen in epilepsy; and the more that there is a tendency to convulsive distortion of countenance and limb, and the more that saliva is excreted from the salivary glands, in that proportion does the disorder recede from true apoplexy and ally itself with epilepsy. From hysteria apoplexy differs by the absence in the latter of that sense of constriction about the throat, called globus hystericus; which, in some forms or grades of the hysteric disorder, is so exceedingly urgent. From intoxication the distinction is to be taken by the absence, in apoplexy, of any vinous or spirituous smell in the breath; by the respiration being more stertorous, and by the patient being for the most part more insensible to temporary rousing by shaking or loud talking.

Prognosis.—A person having once been apoplectic is scarcely ever the same person again that he had been prior to the attack, so that in one sense we may say the prognosis is almost without exception unfavorable. Apoplexy indeed, occuring in early life, in a full, plethoric, vigorous individual, and induced by some evident excitation, may be taken as an exception to the rule now laid down; but the exceptions are rare, and apoplexy of old age always leaves either an enfeebled understanding, an impaired muscular energy, or at the least a more than original tendency to its occurrence again.

The favorable signs, in respect to the prospect of recovering from the present attack, are the senses being but little impaired, the breathing becoming more free and easy, the pulse more natural or less jirky and obstructed, warm sweats breaking out, the occurrence of spontaneous hæmorrhage, and hæmorrhage taking place either from the hæmorrhoidal vessels or from the nose.

The unfavorable signs are the protraction of the insensibility beyond the third day, the pulse becoming still more oppressed and hard, fever supervening, though in some cases the re-action of recovery is accompanied by fever, so that Hippocrates puts this down as one of the favorable signs; when, however, fever occurs while the patient remains heavy and oppressed, we should say, the degree of fever is almost the degree of danger. Cold, clammy, and partial sweats are also dangerous prognostics, a dribbling of saliva from the mouth, red heavy appearance about the eyes, and cold extremities, all forebode ill. A dilated pupil is universally allowed to be a bad sign; but we are told, by Dr. Cooke and others, that some of the worst cases of apoplexy are accompanied by a remarkably contracted pupil.

Treatment.—During the paroxysm, the patient, if possible, should be laid in a spacious and airy apartment, and all causes removed that impede respiration; the head, and this direction is not perhaps always sufficiently attended to, should be placed high on the pillow; pillows too, or other supports, should be put under the shoulders, so that there should be as little bend as possible in the neck. All ligatures or tight dress should be as speedily as possible loosened, and some have directed the feet and legs to be put into hot water. Blood is to be withdrawn in greater or less quantity, according to the degree of arterial action that may be indicated by the state of the pulse; if this be not high, and there should seem a collapse of the system, and a state somewhat similar to what surgeons call concussion of the brain, it will be better to defer the bleedings till signs of reaction present themselves; but bleeding should never be deferred in the full sanguineous attack, and where there is every mark of plethora and high action. One or two pounds may be taken at once, and repeated in five or six hours afterwards should the stertor and high action continue. The following day the bleeding may be again repeated if we appear to be gaining a little ground without having gone far; but we must now be fearful of carrying the evacuation too far, lest we induce a collapse, which, under the present circumstances of the brain, would not be likely to be recovered from. It is not here as it is in some forms of active and sthenic inflammation, where faintness is a state of things rather desirable than otherwise; or, at any rate, if we stop the internal flow of blood by the production of faintness, we at the same time may do still more injury to the brain's energy than we have done good. Indeed, than bleeding in apoplexy, nothing can be conceived a nicer point, and more requiring a tact and judgment which can scarcely ever be assisted by abstract precept, but must be guided by circumstance. We have seen patients bled out of insensibility, and again bled into it, by a too free repetition of what in the first or perhaps second instance was good practice. When a large quantity of blood is demanded, it is for the most part best to take it from the arm, especially if there be any want of dexterity in the operator in respect of the jugular vein or temporal artery, for it is not perhaps of so much consequence from what part the blood is taken, as whether you take the proper quantity. Some, indeed, have said that, in point of fact or effect, there is no such thing as local blood-letting. This position does not appear to be correct, but we are often apt to infer erroneously in respect to the immediate depletion of vessels, and causing blood to be diverted away from the channels into which it is flowing.

Purging next to bleeding seems one of the most important items in the treatment of apoplexy; but we are often prevented from getting down any thing of much bulk or substance, by the closed state of the mouth, and the interrupted deglutition. In this case some calomel may be introduced forcibly upon the tongue, or, what gives us a better chance of speedy operation, two or three drops of the croton oil may be introduced in the same manner.

In respect of emetics opinion varies: it has been supposed that the collapsed oppressed state of the system, which they occasion, is likely to prove an impediment to restoring the brain's energy. In most instances however the stomach pump might be employed; and, should the apoplexy have been induced by any poisonous substance taken into the stomach, or should the disorder be one simulating apoplexy from poison or spirituous liquors, we may do a great deal of good; and if that is not the case we cannot have done much harm.

Stimulant enemas, as the following, may be thrown up the rectum.

℞ Vini aloes f. ℥iij.
Aquæ puræ f. ℥x.

Fiat enema.

Take of wine of aloes three fluid ounces, water ten fluid ounces. Mix them and make an enema.

Or the turpentine enemata may be employed.

℞ Ol. terebinth. f ℥iij.
Aquæ menthæ pip. f. ℥x.

Fiat enema.

Take of oil of turpentine three fluid ounces, peppermint water ten fluid ounces. Mix for an enema.

Or a few drops of the Croton oil may be mixed with a small quantity of crumb of bread, and be introduced into the rectum as a suppository.

After bleeding and purging, blisters may be applied to the nape of the neck, or to the calves of the legs; and, should the insensibility continue, it is usual to apply sinapisms of mustard and crumb of bread, made into a poultice with vinegar, to the feet and ancles. It is doubtful, however, whether much good is ever effected in the powerful kinds of apoplexies by these stimulants and counter-irritants, and the practitioner rather has recourse to them with a view of satisfying anxious and distressed friends and relations than with much hope of their proving efficacious.

The head should be kept cool by the application of a spirituous lotion should morbid heat be generated, and nothing is perhaps better for this purpose than a mixture of spirits of wine and water, or, in the absence of it, common gin and water. If we have recourse to a pharmaceutical composition for this purpose, the proportion of seven ounces of the liquor. ammon. acet. with one ounce of the nitric ether, or half an ounce of sulphuric ether, will answer our purpose (see *Phrenitis*).

We scarcely need go into the requisites of treatment during the progress of recovery from the paroxysm. Should febrile heat prevail, saline aperients and refrigerants are to be administered, as in the case of other febrile complaints; the bowels preserved gently open; and, in the instances of threatened collapse or sinking, the subcarbonate of ammonia should be administered, as directed under the head of fever.

'Apoplexy being so very fatal a disease, it is incumbent on the physician, in all cases where he has reason to suspect a predisposition to it, to employ steadily such prophylactic measures as are calculated to avert the danger. A cool spare diet, abstinence from all fermented or spirituous liquors, regular exercise, abridging the usual number of hours allotted to sleep, keeping an open body, and in some instances establishing a drain by means of an issue or seton, are those on which his chief reliance is to be placed.'—Gregory.

It will be necessary, says another author, to enquire into the state of the viscera during the after treatment; if these have obviously been deranged, before the occurrence of the paroxysm, they must be especially attended to; and the stimulants, which it may be thought necessary to administer, require, for the most part to be modified and corrected by that class of medicinals that are termed deobstruent or alterative; which are, in fact, those that by acting gently and generally upon the secretions obviate as much as may be the disposition to these irregular impetuses of the circulation.

389. *Palsy.* Paralysis.—In reference to palsy the reader is requested especially to advert to and recognise the habits of the nervous system, as pointed out in the preliminary extracts from authors on the several kinds, and species, and grades, and complexions, of nervous disorder.

Symptoms.—Palsy is characterised by an abolition or suspension of voluntary power, or of sensation, sometimes of both, preceded sometimes by a numbness and sense of weight in the head, or vertiginous affection; sometimes a sense of creeping, or numbness, precedes the full attack; and occasionally there is a twitching or catching of the member affected. It has been supposed that when paralysis is thus ushered in by nervous feelings, such as those just mentioned, the disease is then in some portion of the nervous system unconnected with the brain; but when it occurs suddenly, or without these precursors, that then the effect has been brought about by some prior condition of the cerebral system.

Causes.—The predisposition and excitants of palsy are for the most part minor degrees of those which dispose to and excite apoplexy. Sometimes, however, as may have been inferred from what has been previously remarked, the paralytic disorder is purely local and independent of the cerebral system, as when it is induced by a diseased condition of the nerve supplying the muscles which become paralysed; at other times a particular poison, as of lead, will bring on palsy without any obvious effect upon the brain; occasionally the disorder is purely sympathetic, as in the instance of paralysis from worms; at times a certain kind of rheumatism will engender paralysis; and it has been already remarked that some pathologists, from the alliance of rheumatism and palsy, have proposed to designate some kinds of rheumatism, paralytic. The direct application too of cold will, under certain circumstances, create a disordered condition of the sentient and moving organs, which would be justly entitled to the appellation of paralysis, and that without occasioning any obvious derangement in the encephalon; so that palsy is at times a sort of minor apoplexy, or a degree of the same disorder, and at other times apparently independent of the brain.

Distinctions.—Palsy is distinguishable from apoplexy by the absence of stertorous breathing, and by the loss or suspension of sense and motion being only partial. The distinction between cerebral and merely sympathetic palsy must be taken from a careful attention to the circumstances of the attack, by enquiring into the condition of the chylopoietic organs, by ascertaining whether there be any reason to suspect the existence of worms, and by learning whether there are any other particulars con-

nected with the attack beside cerebral disturbance.

Prognosis.—That palsy which results from fully formed apoplexy is seldom thoroughly cured; or, if the muscular energies and volition be restored, it is often at the expense of lesion of the intellectual faculties. It has been remarked that when cerebral or apoplectic palsy, if we may so express ourselves, occurs on the left side, the chance of restoration is less than when the right side is affected. When the paralysis is from causes acting upon the nerves only, the parts have been restored occasionally to their wonted sensation and motion by the occurrence of a fever—which by the way has been known to produce a temporary cure, even of idiotcy, or rather total loss of memory; but the condition that had been removed has been found to recur when the fever subsided. A remarkable case of this kind is related in the Edinburgh Review, if we recollect right, quoted from Mr. Tuke, the proprietor of a lunatic asylum. These mutations and suspensions of disordered states, by the intervention of others, are among the most extraordinary and interesting phenomena that are manifested in connection with morbid processes. The unfavorable circumstances and prognosis in palsy are the simultaneous deprivation of both feeling and motion, with a gradual wasting of the affected limb. The palsy we may say that results from an affection of the brain is always likely to be more permanent, and less under the influence of remedial measures, than that occurring as a mere nervous affection.

Treatment.—Should there be much plethoric condition, or seeming congestion of vessels, bleeding and active purgatives will be required, as in apoplexy. On the other hand, if the deprivation of power be rather nervous than cerebral, rather adynamic than apoplectic, stimuli will be called for, such as blisters, electricity, or galvanism, friction, and the several medicinal excitants that are employed to rouse nervous energy, such as mustard seed, horse radish, ammoniated tincture of guaiacum, carbonate of ammonia, valerian, assafœtida, &c.

Prescriptions from Dr. Gregory, Dr. Hooper, and Dr. Uwins.

℞ Infusi cascarillæ f. ʒviij.
Ammoniæ subcarb. gr. v.
Confect. aromat. ℈ß.
Sp. armoraciæ comp. f. ʒij.
Fiat haustus: ter de die sumendus.

Take of infusion of cascarilla eight fluid drachms, subcarbonate of ammonia five grains, aromatic confection ten grains, compound spirit of horse-radish two fluid drachms. Mix into a draught.

℞ Confectionis aromat. ℈j.
Ammoniæ subcarb. ℈ß.
Aquæ puræ f. ℥iß.
Fiat haustus.

Take of aromatic confection a scruple, subcarbonate of ammonia ten grains, water a fluid ounce and a half. Mix into a draught.

℞ Guaiaci pulv. ℈ß.
Tinct. guaiaic ammon. f. ʒi.
Pulv. acaciæ ℈ij
Syrupi croci f. ʒiß.
Aquæ pimento f. ʒxiij
Fiat haustus.

Take of guaiacum in powder ten grains, ammoniated tincture of guaiacum a fluid drachm, powder of gum arabic two scruples, syrup of saffron a fluid drachm and a half, pimento water thirteen fluid drachms. Make into a draught.

Valerian, in the form of ammoniated tincture, is an excellent medicine; or valerian root may be infused in the proportion of a quarter of an ounce to half a pint of water, and half this quantity taken twice a day. It is questionable whether the virtues of valerian may not be too little regarded in the present day; but, upon the whole, we are not to expect a great deal from stimulants of this kind as permanent medicinals. In old cases, where the secretions as well as the nervous energy may be out of sorts, a combination of guaiacum with deobstruents, as in the following formula, may be tried.

℞ Guaiac. resin. ʒij.
Pil. hydrarg. ʒj.
Pulv. digitalis ℈j.
Opii pulv. ℈ß.
Mucilag. acaciæ q. s.
Fiat massa in pilulas xlij dividenda. Suma ij vel iij nocte maneque.

Take of guaiacum two drachms, blue pill one drachm, powder of foxglove one scruple, powder of opium half a scruple. Mucilage of gum arabic as much as will be sufficient to make into a mass, which is to be divided into forty-two pills, two or three to be taken at night and morning.

The nux vomica, the arnica montana, and the rhus toxicodendron, have all been tried in palsy, especially the former, and they unquestionably possess an influence over the nervous system; it may, however, be considered doubtful, whether any of them are gifted with influence of a permanent kind in old standing palsies, and whether the temporary excitation which they occasionally produce may not in some instances prove worse than useless. Certain it is that, when the palsy has connexion with chronic irritation in the brain, there is some danger of stimulating the vascular as well as the nervous system by means of these medicinals, to an extent destructive of our own design in their administration. This objection lies against the voltaic electricity, if unseasonably, or without due care applied; but upon the whole we should say that galvanism under proper regulations promises to be of more service in some cases of old standing palsy than any remedy which has hitherto been proposed. Bath waters, warm sea bathing, vapor baths, with or without medicinal impregnations (and these impregnations are of questionable efficacy) shampooing, and a determined course of friction, seem principally useful when the paralysis partakes of an arthritic, that is, of a gouty or rheumatic character; for in stiffness and want of power over the limbs, connected with these dispositions and states, much good may be effected by a judicious employment of one or more of these several remedial processes; they combine the advantages of exciting hope and in-

spiring confidence, with their more positively physical operation; and the reader will recollect the curious fact, stated in the introduction to the present class of diseases, that supposed metallic tractors, while they were employed under the conception on the part of the patient of their being the real thing, operated a decided and powerful effect upon muscles which refused to be called into action by the common excitants of muscular energy.

In all cases of remedial attempts to overcome palsy we must be careful to keep the secretions active, and not to stimulate the brain to an excess.

The following composition may be employed with much benefit in some cases of chronic palsy, particularly where there is still a disposition manifested to cerebral irritation.

℞ Decoct. aloes comp. f. ℥vj.
Ammoniæ subcarb. gr. v.
Aquæ puræ ℥vj.
Fiat haustus.

Take of compound decoction of aloes six fluid drachms, water six fluid drachms, subcarbonate of ammonia five grains. Mix them into a draught.

The student will perceive, by turning to the nosology, that paraplegia is one of the varieties of palsy pointed out by Dr. Cullen. This name is given to a loss of power over the lower extremities, or, as it is expressed, half the body divided, not as in hemiphlegia, but transversely. Much discussion has taken place in respect of the condition of parts necessary to the production of this species of palsy, when it occurs without an obvious affection of any portion of the spinal chord. Dr. Baillie has brought forward arguments in support of the principle that this is a cerebral palsy as well as hemiplegia; and he has adduced the facts that giddiness, drowsiness, vertiginous affections, &c., accompany it. The probability, however, is, that it may at different times be both cerebral and spinal; that is, that some altered condition of the spinal chord, without being obvious to the senses may prove, occasionally equal to the production of this kind of paralysis without any primary affection of the brain, and that at other times the original cause of the paralysis may be in the brain, and the direction of it to the lower extremities regulated by the particular parts of the brain which may be implicated. Affections of the spinal chord, and its investing membranes, we may here take occasion to say, have been recently investigated with considerable minuteness, and no examination as to structural change is at present considered satisfactory; we mean more especially in reference to nervous changes, that do not take the spinal appendage to the brain, as well as the brain itself, or as it is called by some the cerebral brain into recognition.

The following is an outline lately given by Dr. Abercrombie of the general pathological changes of which the spinal chord is susceptible. For the record of cases illustrating the principles we must refer to the work itself of Dr. A., which is entitled Practical Researches on Diseases of the Brain and Spinal Chord; a work from which we have already made a considerable extract in the introduction to the present class of morbid affections.

1. Acute inflammation of the membranes, or what we call meningitis, of the chord.

2. Inflammation of the body of the chord terminating by ramollissement or suppuration.

3. Serous effusion in the spinal canal.

4. Extravasation of blood in the spinal canal, or spinal apoplexy.

6. Fungoid disease and thickening of the membranes.

6. Induration of the chord.

7. Compression of the chord by new formations within the canal, as tubercles, albuminous depositions, hydatids, and ossifications of the membranes.

8. Destruction of a portion of the chord.

9. Concussion of the spinal chord.

10. Certain affections of the bones of the spine.

We do not mean to say that the above affections of the spinal chord are causes producing, or circumstances in connexion with paraplegia; we merely embrace the opportunity, which no part of the nosology better affords us, of reminding the reader of the connexion between spinal and cerebral ailments, and of the necessity of preserving in the recollection a view of this connexion when the different shapes of palsy are made the subject of pathological enquiry as to their nature and seat and rationale. At the same time let us again remind the student that paralysis of all kinds, and in all localities, oftentimes presents itself without any morbid manifestation of a structural or local kind whatever, and when we take into account that a complete paraplegia of a temporary kind will be consequent upon a few ascarides in the rectum, which will yield with the destruction or expulsion of these animalculæ, we must acknowledge that many changes take place in the nervous system which morbid anatomy cannot discover, but which pathology must carefully collect and appreciate.

The difficulties (says an author whom we have already so many times quoted in the present article) which we have to encounter, in any enquiry into the pathology of paralysis, are greatly increased when the investigation is extended to those cases of general and partial palsy which are to all appearance totally unconnected with any derangement of structure, or function, in the encephalon. That such cases do occur is unquestionable; and it must be left to future enquiries to determine in what manner these apparent inconsistencies are to be reconciled.

In the year 1820 I had an opportunity of seeing an instance of general palsy, of the kind now alluded to, the history of which is fully detailed in the London Medical Repository. The disease ran a very singular course, terminating after the lapse of about eight months in the complete recovery of health. During the whole of this long period, there did not occur one symptom which could warrant me in looking to the brain as the source of the disorder. The vital and natural functions were also undisturbed, nor was there any evidence of disease within the theca vertebralis. It is obvious, therefore, that this disease was in its pathology totally distinct from the or-

dinary forms of palsy. A case very similar in its leading symptoms, but different in its termination, is recorded by Dr. Powell in a paper containing many important pathological views of palsy. We bring forward this case among others in support of the opinion that paralytic affections, both partial and general, often originate in a peculiar condition of the nerves alone; that they are independent of any morbid affection of the blood-vessels of the head: and that they are produced in many instances by cold, and in some by sympathy with particular states of the stomach, or other distant local irritations.

The palsy from lead is the one to which Dr. Cullen particularly alludes in his variety entitled Paralysis Venenata; but, as we shall have occasion to speak of the effects of lead under *Colica Pictonum*, we need not in this place enlarge on this variety.

390. Order 2. Adynamic Disorder. Adynamiæ.—Adynamia is a vague term to apply to an order of diseases, since there are very few affections which the term would not characterise, the strict meaning of it being deficient power. The genera of the order are fainting (syncope), dyspepsia, hypochondriasis, and chlorosis (green sickness).

391. *Fainting*. Syncope.—Fainting is sometimes nervous, strictly so speaking; at other times it is organic, or dependent upon some affection of the heart. 'To maintain the faculty of perception clear and true to the impressions that are made on the external senses, the motion of the nervous power which connects it with those senses must be equable and uniform; and, to maintain the action of the heart in a firm and regular order, it is necessary that the blood should flow into it in an equal and uniform stream; for if its volume be altered from any cause, whether of obstruction, surcharge, or deficiency, its motion will be checked and enfeebled; the brain and respiratory organ will participate in the debility, and syncope be a frequent result. And hence we may account for the fainting which frequently takes place on the commencement and sometimes on the close of venæsection. On tying the arm for this purpose a considerable stream of supply is cut off, and ten ounces of blood flow, in perhaps five minutes, into a basin, which would otherwise have flowed into the heart in the same period of time. The volume of blood is hence diminished, and the heart must collapse or contract itself in proportion. In many habits this is done with great facility, but in others, and especially where there is a feeble supply of motific or irritative power, the contraction takes place slowly and irregularly, and with a considerable degree of flutter, or clonic spasm; and fainting or a temporary failure of sensation is the necessary consequence; during which the alternating systole is very feeble, and the blood ceases to flow at the puncture. This effect is ordinarily ascribed to a loss of the stimulus of distension, and there may be some degree of truth in such an explanation. But that there is something beyond this is certain; because, on removing the ligature from the arm, this stimulus is once more obtained; for the blood, instead of flowing away at the venous orifice, now takes its proper course and flows back to the heart. Yet we see almost as often a syncope produced at this moment, and consequently by a revival of the distension, as well as by an interruption of it. The fact is, that the heart, which by this time has accommodated itself to the diminished volume of the returning current, has now once more to change its diameter, and to expand itself in proportion to the increased measure and momentum of the in-flowing tide; and as a change in its diameter produced a syncope in the former case, a change in its diameter in like manner produces it in the latter.

For the same reason we see swooning takes place when any extensive range of blood-vessels that have been pressed upon by every other means suddenly acquire a power of dilatation; as when a large cavity is formed in the abdomen by the process of tapping for an ascites, or on opening an extensive abscess in any other quarter.

But the flow of sensorial power from the brain may also be suddenly exhausted or checked, or perhaps its secretion impaired; and syncope may ensue from this source, the action of the heart being diminished not primarily but secondarily, or by sympathy with the state of the sensorium. In fainting from entonic passions or emotions, as a sudden shock of vehement joy, the sensorial power is perhaps abruptly expended as also in severe pain. In fainting, under the influence of atonic passions, as fear, or heart-sick grief, this power is unquestionably checked in its regular flow, and probably checked also in its secretion; (it will be observed that the author, whom we are now quoting, speaks of the nervous power as effected through the agency of a secreted fluid, as being indeed a nervous fluid,) as we have reason to believe it is where fainting occurs from a repulsion or retrocession of gout, exanthems, or various other diseases. And to the same cause may be referred those cases of swooning which in some idiosyncracies, or indispositions of body, are well known to take place on exposure to particular odors, as those of cheese apples, of roses, lilies, and other fragrant plants. Where it has followed instantly upon acrid poisons, there can be no doubt that these have induced a rigid or entastic spasm upon the muscular fibres of the heart; and, where the poisons are purely narcotic, the living or instinctive stimulus is suddenly extinguished or carried off, and the nervous system becomes an exhausted receiver.

Syncope then in its simple state, as unconnected with any structural disease of the heart or its adjoining vessels, seems to appear under the following modified forms or varieties:—α. Inanitionis (from inanition). The swooning produced by fatigue, long fasting, or a sudden and excessive discharge of any fluid whether natural or morbid, accompanied with a sense of inanition and great prostration of strength. β. Doloris (from pain), preceded by severe pain or irritation of body; internal, as from poisons, flatulency, or worms; or external, as from wounds, or other injuries. γ. Pathematica (from mental emotion), preceded by an exercise of some sudden and overwhelming passion or emotion. δ. Metastatica, accompanied with a

retrocession or repulsion of gout, exanthems, or other diseases.

The degree and duration of the paroxysms depend upon the peculiarity or violence of the cause, the extent of the sensorial exhaustion, or the nature of the constitution, and hence must greatly differ in different individuals. In some cases it ceases in a few minutes, and the patient, though incapable of speaking, retains enough of perception and sensation to be conscious of his own disorder, and to understand what is passing around him. The pressure and irritation of flatulency, in dyspeptic and hypochondriacal habits, are often sufficient of themselves to produce a fainting of this kind. In other cases the general feeling and understanding fail totally, and the pulse is scarcely perceptible. Occasionally the sensorial power has been totally, as well as suddenly exhausted, and the syncope has run into asphyxy, and even proved fatal

When not assisted by medicine the system recovers itself by the gradual accumulation of sensorial energy that must necessarily take place so long as the living principle continues during such a state of quietism; aided unquestionably by the continued action of the instinctive or remedial power of nature, which is always aiming to repair what is amiss. The process of recovering, however, varies almost as much as that of sinking. Some revive almost immediately without any inconvenience or sense of weakness whatever; while others improve slowly and almost imperceptibly, and require many hours before they fully regain their self-possession. In various cases the head becomes clear as soon as the pulse becomes regular; while, not unfrequently, the recovery is accompanied with a confusion of ideas, vertigo, and head-ache.

As this disease is always attended with an irregularity in the flow of nervous power, and some degree of spasmodic action, entastic or clonic about the heart, the best remedies we have recourse to, during the paroxysm, are antispasmodics and stimulants; and those that are the most volatile are the most useful. Hence the advantage of admitting a free current of cold air, sprinkling cold water over the face, and pouring a little of it if possible down the throat. And hence also the advantage of holding ammonia, the strongest vinegar, or any other pungent odor, to the nostrils. A recumbent position is always advisable as most favorable to an equable circulation of blood; and irritating and warming the extremities by the friction of the hand, or the application of rubefacients, will commonly be found to expedite the recovery, upon the principle that, in a chain of organs united by sympathy or continuity, an impression produced on the one extremity is sure to operate on the other. As soon as the patient is capable of swallowing some spirituous cordial, as a glass of wine or brandy and water; fetid tincture, or the aromatic spirit of ammonia, or of ether, should be administered, and the occasional cause should be sedulously avoided in future.—*Good.*

392. *Dyspepsia.* Indigestion.—To describe the symptoms of dyspepsia would be to run over the whole ground of nervous feelings. The dyspeptic is hypochondriac, has wandering pains over his body, and uneasy sensations about his limbs, as well as immediately in the stomach and connected viscera; his countenance looks dejected; the surface of the body loses its healthy complexion; the secretions and excretions are irregular; the tongue is foul and clammy; and, in a word, the whole system in a state of derangement.

Causes.—The existing causes of indigestion are generally sufficiently obvious. Alternations of temperature, affections of the mind, spirituous liquors unduly taken, the immoderate use of tea, a sedentary life, intemperate study, and in fact all excesses which tend to deprive the system of power will have the effect, in the dyspeptically disposed, of interfering with the digestive process, as well as the more obvious and necessary sources, those of eating too much, or taking food of an improper quality.

With respect to the proximate cause of indigestion, or the circumstances by which it is constituted, it evidently consists, in the first instance, of a disordered condition of the muscular fibres of the stomach, and a disordered secretion from the villous coat of the organ; hence the ingesta, instead of being duly acted upon mechanically, chemically, and, if we may so say, vitally, run into those changes which unorganised matter is obnoxious to; fermentations take place, eructations of gas are the consequence; pains of the stomach are brought on, partly by the irregularity in the fibrous action of the stomach, and partly by the acrimony of its secretion, and of the undigested mass: a general morbid susceptibility is induced, connected with want of muscular energy; this torpor is extended to the duodenum, and to the liver, and to the pancreas,—the functions of these organs are in consequence performed lamely; in this manner the original disorder of the stomach is both extended to other parts, and increased in the organ itself first affected; the cerebral system of sympathetic nerves partakes of the deranged condition, and thus sympathetic grows out of local disturbance, and the whole frame, as we have said, comes to participate in the induced affection.

Dr. Wilson Philip, who has written expressly on indigestion, divides it into three stages; the first, in which the stomach itself is alone or principally injured in the way just pointed out, of mere functional or nervous, and muscular and secretory derangement; in the second stage he supposes an inflammatory condition to have been induced, marked by epigastric tenderness and hard pulse; and in the third consecutive disorders are occasioned, and the dyspeptic becomes phthisical, or otherwise disordered, according to constitutional tendencies or accidental circumstances.

Dr. Paris, Dr. James Johnson, and Dr. Uwins, who have all recently written on disordered digestion, contend that the inflammation assumed by Dr. Philip is for the most part mere tenderness, and they deny that any thing like this regularity of division into stages does in point of fact obtain. At the same time they allow that inflammatory threatenings, and phthisical, as well as other tendencies, should be watched over and counteracted, and he that

should confine his observations to the mere condition of the stomach itself, under circumstances of dyspepsia, would take by far too limited a view of its nature and remedial requisites.

Dr. Mason Good, too, dwells particularly on the necessity of extending our views out from the mere stomach derangement, and taking into account the condition of the intestines, the liver, the pancreas, and the spleen. The debility, and indeed torpitude, of the intestinal canal, is evident, he says, from the habitual costiveness which so peculiarly characterises this affection. Whether this be direct or indirect, intrinsic or sympathetic, as harmonising with the weakness of the stomach, it is not easy to determine; but nothing can be a stronger proof of the great inactivity of the intestinal tube, from whatever cause produced, than the feebleness of its peristaltic motion, notwithstanding the pungency of the acid, and other acrimonious matters, that are so frequently formed in the stomach, and hence so frequently diffusing their asperity over its inner surface.

The imbecility of the liver is equally obvious in most cases from the small quantity of bile that seems to be secreted, or its altered and morbid hue as evinced by the color of the fæces, which in some instances are of an unduly dark, and in others of an unduly light tint, and possibly from the inactivity of the intestines themselves, whose peristaltic motion is in a great measure kept up by its stimulus.

It is highly probable that the pancreas and spleen are both also affected in many cases of dyspepsia. We know that the pancreas pours forth a considerable portion of the fluid which holds the solid part of our aliment in solution; while in most cases of dyspepsia, brought on by a habit of drinking spirituous liquors, the spleen is evidently affected as well as the liver.

Distinctions.—Hypochondriasis and dyspepsia are said by the dividers of disease to be different, inasmuch as the former is a disorder of the nervous system, which only brings the digestive organs into consecutive sympathy, while the latter is a complaint of the stomach originally, and the nervous system is the part secondarily affected. It is also predicated of hypochondriasis that it affects principally individuals of a melancholic temperament, while dyspepsia is common to all constitutions. The student will, with a recollection of these intimations, which have in the course of the present article been more than once given, respecting the nature of medical nomenclature, know how far to care about these niceties of nominal distinction. It is, however, always right both in reference to pathology and practice to endeavour at tracing the first link in the chain of morbid association, or to ascertain the primary locality of affections that are thus located both in a primary and secondary way.

Prognosis.—From mere derangement in the digestive process much is not to be dreaded, unless it continue, and in its protraction come to elicit latent disorders of the frame that only awaited an excitant to develope themselves. Dr. Wilson Philip has argued at length in support of a dyspeptic phthisis, and has replied to others who are a little inclined to speak contemptuously of this designating precision; and it must be allowed that an individual with a phthisical tendency, ready to break out upon any exciting cause, may have consumption establish itself as the result of a stomachic derangement; this last having been formidable and protracted. Organic affections of the stomach, as schirrous pylorus, may also be engendered by the long continuance of dyspepsia; but it must be allowed that these specific diseases often occur during the time when the digestive process is no otherwise interrupted than as a consequence of the disorganisation referred to.

Treatment.—It is especially requisite for the dyspeptic to relinquish with determination and perseverance those practices which have induced the disorder; intemperance of all kinds must be given up, even immoderate studies: indeed than these, connected with the anxiety of mind which frequently accompanies them, there is not probably a more fruitful source of the malady now under notice. It is the position of the body also that partly operates unfavorably under these circumstances. Severe and long continued study, says Dr. Good, who himself was a hard student, protracted as I have known it through ten hours a day for many months, without any relaxation or change of pursuit, must give way to the exercise of walking or riding, and this not occasionally but daily, and to the still better cordial of cheerful conversation. The last is of very great importance, and without it even exercise itself will be of little avail; for the mind, accustomed to a certain track of intellectual labor will otherwise relapse, even while riding or walking, into the same habitual course, be dead to the most fascinating prospects around it, and become exhausted by its own abstractions. And it is to characters of this kind perhaps, more than to any other, that the amusements of a watering place promise ample success; where the general bustle and hilarity, and the voluntary forgetfulness of care, the novelty of new scenes and new faces, and new family anecdotes, and the perpetual routine of engagements that fill up the time with what would be otherwise trifles and frivolities, reverse the mischievous order and monotony of the past, break the sturdy chain of habit and association, and give occasion to the worn out sensory to refresh itself.

Mere change of air, as well as of scene and amusements, is often wonderfully forcible in breaking into the morbid links of the chain of diseased actions, which constitute the worst forms of dyspepsia, and a very short removal, even from one part or outlet of the town to another, will often effect a considerable share of good. I have known, says Dr. Uwins, individuals who have felt themselves vaporish and dull, and dyspeptic, when residing in Westminster, to become, comparatively indeed, conspicuously free from their complaints as soon as they shall have removed to the north-west suburbs; but there is something inexplicatively operative at times in mere change of air, when the new atmosphere may not abstractedly be so salubrious as the one left.

With respect to the medicinal indications, in

dyspepsia, they are obviously to rid the stomach of the offending material, and to get the muscular and secretory tone of the organ into that state of vigor which shall insure against future loads of unhealthy secretions. Emetics are occasionally required, either of ipecacuan or sulphate of zinc, a scruple or half a drachm of this latter often doing the good that the ipecacuan or antimonial emetic refuses to accomplish. Gentle purgatives are also of course requisite; and, when the liver is obviously engaged with the disordered condition, it is right to combine with the purgative material some blue pill, or small doses of calomel. It is right also, when thinking of purgative medicinals, to take into account the morbid susceptibility of the nerves and organs implicated, otherwise, by employing indiscriminately drastic materials to dislodge offending colluvies, we may defeat the object for which we instituted the cathartic process, and add to rather than abate irritation. For the sake of accomplishing this combined intention of allaying irritation, while we produce evacuation, some one of the vegetable narcotics may be advantageously combined with the purgatives, of which few formulæ will be found more efficacious and applicable in most dyspeptic states than the following.

℞ Extract. hyoscyami ʒß.
Extract. colocynth. comp. ʒj.
Hydrarg. submuriat. gr. ij.

Fiat massa in pilulas xxiv. dividenda; quarum sumat æger ij vel iij semel, bisve in die, ut opus erit.

Take of extract of henbane half a drachm, compound extract of bitter apple a drachm, calomel two grains. Mix them into a mass, which divide into twenty-four pills, and let two or three be taken once or twice a day according to circumstances.

Exceedingly small doses of calomel, such as will be found in the above formula, or the addition of only one grain of blue pill to other purgatives, will not seldom prove highly useful to the dyspeptic, whose morbid irritability of stomach would reject, or at least be injured by, larger quantities of mercurials; and some persons, dyspeptics particularly, have an extreme sensibility to mercury, when given in any beyond very minute doses.

Acidities must of course be corrected by one of the alkalies, or magnesia; the last is often exceedingly applicable to dyspepsia, for while it corrects the stomach acidities, it forms a salt with such acidity that is purgative, and when the dyspeptic condition is connected with the tendency to gravel, which is not seldom the case, a tea spoonful of the common or subcarbonate of magnesia, taken about twice a day in a glass of cold water, will do much good.

The more positive alkalies, as of soda and potass, will also prove beneficial in correcting the acidities of the stomach; and for the most part it is best to employ the mild or aërated alkalies, than the caustic or pure.

Acids also will occasionally be found good correctives of stomach disorders, even although the condition which they are given to counteract is one of acidity. But, as remarked by Dr. Good, it is not always from acid formation that the dyspeptic suffers. The eructations, says this author, are often of a compound and very offensive taste, and give to the breath the smell of carbureted hydrogen gas, or rotten eggs; as though the gastric juice were incapable of performing its proper office, and the food were retarded in the stomach till the process of putrefaction had commenced. In this case, instead of avoiding acids, we should recommend a free use of them, from whatever quarter they may be obtained, as they not only tend to correct the fœtor, but to strengthen the stomach. The mineral are the most powerful; and of these the sulphuric is by far the pleasantest; but, in common with the rest, it labors under this disadvantage, that only a small quantity of it can be taken at a time, because of its corrosive quality. It may be advantageously employed as a medicine, but for acidulated diet-drinks it must yield to the vegetable acids. These are of three kinds, native, distilled, and such as are obtained by fermentation. The first are commonly the most grateful, and especially when they exist in the form of fruits; but, as in most of these they are combined with a fermenting power, they are apt in weak stomachs to set free a very large quantity of air, and consequently to produce a very troublesome flatulency, and even promote the ascescent disposition of the organ. The citric and oxalic may be exceptions; and there may also be a few others, but they are not numerous, and where these cannot be procured we must have recourse to the acids elaborated by distillation, or a fermenting process. The last are called vinegars, whether obtained from malt, weak wines, or sugar; and being themselves, when properly refined, very pure and dilute, they are capable, with a little care, of being rendered highly grateful.

The distilled acids of vegetables have not yet been sufficiently tried, to determine whether any of them possess any specific virtue. They were at one time very generally made use of under the guise of tar water, the whole of whose benefits Dr. Cullen ascribes to the acid of the fir with which the tar was impregnated; but I cannot avoid conceiving that some and not a small part of its good effects resulted from the camphorate or terebinthinate principle which was communicated at the same time. Glauber and Boerhaave seem to have been of the same sentiment; and, as the Norway tar is richer in this principle than the American, we are at no loss in determining why Dr. Berkely preferred the former to the latter. This medicine has experienced the fate of every human discovery, whose praise is carried to extravagance; and, from being esteemed good for every thing, it is now esteemed by many practitioners good for nothing, and has sunk into total disuse. But this is to sink it very considerably below its level. There are many complaints for which it has very fair pretensions; and where the taste is not disliked it will be found a useful remedy in indigestions attended with offensive and putrid eructations.

Having thus expressed himself on the subject of tar water, Dr. Good goes on to the mention of

another remedy which is but little employed as an anti-dyspeptic, but of which some have spoken highly. We may observe by the way that this remedy (charcoal) has likewise obtained the reputation of being the best material for obviating some kinds of costiveness; the dose may be from half a scruple to a scruple, repeated three or four times a day.

By way of restoring tone to a dyspeptic stomach, bitters and other tonics are had recourse to, and occasionally with considerable advantage: in their administration however, we must be careful not to induce the habit of dependence upon these kinds of fillips, and we must likewise withhold them when there is much febrile irritation, with hardness and quickness of pulse. In all cases it may be as well to combine them with slight aperients, so as that their too stimulating action may be obviated; and when we have reason to suppose the sluggishness or irregular action of the stomach has extended itself to the liver, the addition of what in the humoral school of medicine are called alteratives may be still further called for. We shall here put down a few formulæ for answering these different indications.

Antacid, and aperient, and cordial, from Dr. Hooper.

℞ Potassæ subcarb. ʒiß.
Myrrhæ contus. ʒj.
Aloes soc. ʒiß.
Croci ʒß.
Aquæ distill. Oj.
Coque ad ℥xij et liquori colato adde
Tincturæ Cardam. comp. ℥iv.
Syrupi zingiberis ℥iß.
Sit dosis cochlearia duo magna bis die.

Take of subcarbonate of potassa a drachm and a half, bruised myrrh a drachm, Soccotrine aloes a drachm and a half, saffron half a drachm, distilled water a pint. Boil them down to twelve fluid ounces, and to the strained liquor add compound tincture of Cardamum four fluid ounces, syrup of ginger a fluid ounce and a half. Let the dose be two table spoonsful twice a day.

Very similar to this is the decoctum aloes compositum of the Pharmacopœia two table spoonsful of which may be taken twice a day. It is for the most part better to add three or four grains additional of soda to that proportion of alkali which the Pharmacopœia orders, more especially if the acidity of the stomach is considerable.

Soap pills with rhubarb, as antacid and aperient.

℞ Saponis duri,
Sodæ subcarbonatis exsic., āā ʒj.
Pulv. Rhei ʒß.
Aquæ q. s.
Fiat massa in pilulas xxxvj dividenda. Sumat iij nocte maneque, vel omni nocte.

Take of Castile soap and dried subcarbonate of soda of each one drachm, powder of rhubarb half a drachm, water as much as is sufficient to form a mass, which make into thirty-six pills, three to be taken every night, or night and morning.

This last prescription will be found exceedingly applicable when affections of the kidneys accompany disordered states of the stomach.

Stomach tonics with gentle aperients.

℞ Infus. quassiæ f. ℥iß.
Magnesiæ sulphat. ʒj.
Tinct. rhei f. ʒiß.
Fiat haustus: bis die sumendus.

Take of infusion of quassiæ a fluid ounce and a half, Epsom salts a drachm, tincture of rhubarb a fluid drachm and a half. Mix into a draught, to be taken twice a day.

℞ Ferri ammoniat.,
Pulv. rhei, āā ʒj.
Aquæ puræ q. s.
Fiat massa in pilulas xxxvj divid. Sumat iij bis in die ante et post merid.

Take of ammoniated iron and powder of rhubarb of each a drachm, water enough to form a mass, to be divided into thirty-six pills; three to be taken forenoon and afternoon.

Deobstruent and stomachic.

℞ Extracti taraxaci ʒß.
Sp. ætheris nitric f. ʒj.
Infus. gentianæ comp f. ℥iß.
Fiat haustus: bis die sumend.

Take of extract of dandelion half a drachm, spirit of nitric ether a fluid drachm, compound infusion of gentian a fluid ounce and a half. Make them into a draught to be taken twice a day.

The above are more particularly called for when there is reason to suppose the liver requires to be stimulated or emulged.

Antacid and aperient and stimulant.

℞ Magnesiæ subcarb. ʒß.
Sp. ammoniæ aromat. f. ʒi.
Aquæ puræ f. ℥iß.
Fiat haustus.

Take of common magnesia half a drachm, compound spirit of ammonia a fluid drachm, water a fluid ounce and a half. Make them into a draught.

A good stomachic under circumstances of a tendency to gouty affection.

When violent pains accompany stomach affection, so as to constitute what in the schools would be called gastrodynia, the oxide, or what is now more properly termed the subnitrate, of bismuth will be found a useful medicament; it may be given in conjunction with rhubarb.

℞ Bismuth subnitrat. gr. vij.
Mucilag. acaciæ f. ʒiij.
Tincturæ rhei f. ʒiß.
Aquæ menthæ pip. f. ℥iß.
Fiat haustus.

Take of white oxide of bismuth seven grains, mucilage of gum arabic three fluid drachms, tincture of rhubarb a fluid drachm and a half, peppermint water a fluid ounce and a half. Mix into a draught.

Than tincture of rhubarb, in small quantities, very few medicinals are more suitable to a dyspeptic invalid. The Chlorine bath, mentioned under the head of chronic hepatitis, may be

employed in obstinate cases with a prospect of good.

When diarrhœa occurs in dyspepsia, five grains of the blue pill may be given at night, and about a fluid ounce of the cretaceous mixture (the mistura cretæ of the pharmacopœia) two or three times a day. A little tincture of rhubarb may be added to the cretaceous mixture, in order to prevent undue constipation following the diarrhœa.

Blisters to the back will sometimes correct a chronically disordered state of the stomach; or with the same view, of procuring a vicarious or metastatic irritation, the antimonial ointment may be rubbed into the hypogastrum every night.

Friction of the surface, warm clothing, cold, warm, or shower bath, according to circumstances are all of occasional use in correcting dyspeptic conditions of stomach. The dyspeptic must be especially enjoined to keep his extremities warm; and he must be urged even against his inclination to walk and ride in the open air. Galvanism under judicious management may be made very useful in some old standing cases of dyspepsia.

[*Note.*—Although we object to the division of Wilson Philip before alluded to, into the first and second stages, or into that which is inflammatory, and into that which is not; yet when much epigastric tenderness manifests itself in connexion with febrile symptoms, it will then especially be requisite to use caution as to the administration of bitters and stimulants, and in their place very small doses of the vinum colchici, of nitre, or even of antimony will be found expedient; the dose of the last requires, when administered as an antidyspeptic medicinal, to be very small, the eighth or tenth of a grain of tartar emetic being often sufficient. The colchicum wine may be given in doses of from twenty minims to half a drachm, and the dose of nitre is from about six to ten grains.]

Respecting diet no very precise rules can be laid down with propriety, inasmuch as the meat of one is the poison of another; but as it might not be expedient to bring this disquisition to a close without some specific regulations on this head, we shall beg leave to extract from Dr. Good his observations in reference to these particulars.

One substantial meal of solid animal food daily is sufficient for a man in full health in a life of ordinary labor. Yet there are many who, without any labor, are from a long habit obliged to take two or even three. But the habit is bad, and cannot too soon be broken through. It follows therefore, of necessity, that, where the stomach is weak, the toil of digesting one full meal of animal food is the most that should be put upon it. This should take place as nearly as may be to the hour of noon, certainly not later than one or two o'clock, so as to occupy the middle of the wakeful period. The animal food should consist of one dish only; and be confined to such as is lightest of digestion, or as the peculiar state of the stomach may call for; for in both these respects there is a considerable difference. Thus shell-fishes do not always agree with weak stomachs, and will sometimes excite great uneasiness, with pyrectic heat, and even throw out a nettle rash, or some other cutaenous eruption. Yet, where they sit easy and are relished, several of them, as the crab and lobster, are found to neutralise acidity in the stomach more readily and effectually than any other kind of animal food: an effect we should little predict, considering that they give out, on a chemical analysis, a smaller proportion of ammonia than the flesh of quadrupeds, birds, or even amphibials. The food of young animals is less nutritive than that of old, but it is, in general, digested with less irritation. Many writers have arranged the different animals that furnish food in tables founded upon their supposed degree of nutriment. But they have drawn them up with considerable variations, in some instances apparently according to their own fancy. I have not space to enter into a comparison of these, nor is it necessary. Those who have leisure for such a study may turn to Dr. Darwin's, which is perhaps one of the best, and which they will find in his Zoonomia. Generally speaking, the tenderest food is that of the gallinaceous birds: then that of the ungulated quadrupeds; among which the stag, or cervus kind, claims the pre-eminence; and to this succeed the ox, sheep, and hare, in the order in which they are here placed. Yet it should be observed that the last, though less nutritive than the preceding, is more easily digested than several of them; as it should also, that the flesh of animals in their wild or native state, though less coveted by a pampered palate, offers a more wholesome and digestible aliment, and is more perfectly animalised than that of animals cooped up and fattened for the table. Below the hare we may place the web-footed birds that are ordinarily brought to market; and below these the oyster and lobster tribes, and lastly the numerous genera of fishes.

The vegetable nutriment should be such as is least disposed to ferment in the stomach, and hence all kinds of new bread, sweet preserves, confectionary, and pastry, must be sedulously avoided; and the crust of bread, toasted bread, and unleavened biscuits take their place. The farinacea, whether seeds or roots, as rice, wheat flour, in the form of light and simple pudding, and potatoes, may be allowed in moderation. Water too is the best beverage; but, where there is great flatulency, a small portion of brandy may occasionally be added. The only condiments that can be conceded are salt and spices: pickles might be admitted where acids constitute a part of the medical treatment; but they are disposed to provoke a false appetite, and hence to weaken the stomach by overloading it.

From fixing the principal meal so near the hour of noon, it is clear that we suppose the day to commence at a very different period from the ordinary regulations of fashionable life; in which the bed is rarely quitted before nine or perhaps ten o'clock, after a night of imperfect and feverish sleep, when the languid idler immediately proceeds to a breakfast of tongue, ham, and eggs in addition to the ordinary materials of this meal, as though he had been already laboring in the field for two hours; and by means of their combined stimulus fills his stomach with a load,

which might indeed do good to the husbandman, but to himself proves nothing more than a mischievous oppression. Yet to this morning toil of the stomach succeeds, at about two o'clock, the ordinary luncheon in a still more solid shape; followed in the evening by a dinner of numerous courses, with high seasoned condiments and a stimulating change of wines; the real business of this vain and frivolous life perhaps not commencing till the better disciplined peasant has begun his quiet sleep: when, roused by a flow of factitious spirits, and primed for gaiety and gallantry, the votary of pleasure, as it is called, sallies forth to join his comrades at the allotted place of rendezvous, and to pass the midnight in hot and crowded ball-rooms, or in orgies of a still more exhausting nature. Of the whole of this career, the only rational part of it is the luncheon a little after mid-day; this may be copied by the invalid before us, as his dinner, but from all the rest we must carefully shut him out. He should quit his bed by six or seven o'clock in the morning in the summer, and by seven or eight in the winter; and after having risen for an hour he may partake of a light breakfast of milk, cocoa, sassafras, or any other aromatic or warm-flavored tea, with toasted bread, the crust of bread, or sea-biscuits, as observed already. The morning may be devoted to such exercises or recreations as may be most agreeable without producing fatigue. To this will succeed the chief meal of the day, upon the plan already laid down; and a light refreshment of the same nature as the breakfast should conclude the daily diet, a few hours before retiring to rest, which should never be later than eleven o'clock. Sea-bathing or the shower-bath, before breakfast, will considerably add to the means of improvement wherever these advantages can be enjoyed, and particularly when the warmth of the season may give them the character of luxuries.

393. *Hypochondriasis.* Low spirits.—This is the next genus to dyspepsia in the nosology, but nothing further can be said of it in connexion with dyspepsia than what has already been advanced. See *Dyspepsia* (distinctions). As far as it is a vesanic, or more strictly mental malady, a remark or two will fall to be made on it in the order of vesaniæ.

395. *Chlorosis.* Green sickness.

Symptoms.—Indisposition to exertion; stomach derangements to such an extent as to excite a desire for some of the absorbent earths; wandering pains; palpitation; and, at length, from a pallid to a green change of countenance and complexion, are the characteristics of chlorosis. Sometimes, indeed pretty frequently, while there is an irregularity with respect to the menstrual discharge, an obstruction indeed of it, the chlorotic female is worried with fluor albus; and this, with other circumstances, adds to her dejection of mind.

Causes.—It usually happens to girls who are of a scrofulous habit; its exciting causes are all such as tend to debilitate and derange. Disappointed love will sometimes engender it.

Distinction.—The obstructed menstruation of chlorosis may be distinguished from that of pregnancy by the absence of that fulness of the whole frame, especially of the breasts, and the want of the dark areola about the nipples which mark the pregnant state. Although, too, there is often sickness, it is not of that regular morning recurrence that is so often the case in pregnancy. Chlorosis sometimes simulates phthisis and often falls into it; but the cough and the regular hectic are wanting where the malady is merely chlorotic.

Prognosis.—Should there be not much verging towards actual consumption, we may generally pronounce of chlorosis that it is remediable, provided the medicinal plans are judiciously instituted and pursued.

Treatment.—'Give steel,' say the older practitioners. 'Give purgatives,' says Dr. Hamilton. Both are highly useful; but, for the most part, this combination is demanded. The stomach is sometimes too irritable for steel without a good deal of address in the management of it. An emetic may in these cases be premised; indeed, emetic operation is not seldom salutary beyond the mere circumstance of discharging the stomach contents. From the sympathy which this organ maintains with the uterus, it will often be found that the excitation of vomiting is desirable in some inactive conditions of the uterine system, as in the case now before us. For a useful combination of iron, with a purgative, see under *Dyspepsia* (the ferr. amm. with rhubarb). The mistura ferri comp. of the pharmacopœia will be found a good formula in most cases of chlorosis, when the stomach can bear it. The tincture of muriated iron is also useful in doses of fifteen or twenty minims. When fluor albus is an accompaniment, the same dose of the tincture of cantharides may be exhibited. Change of air, exercise, especially on horseback, and mental excitation, ought all, when it can be so managed, to constitute ingredients in the curative process of chlorosis. Marriage is one of Dr. Darwin's prescriptions; and this would be more likely, provided affection was insured and circumstances favorable, than any simple article, or any combination of articles, in the whole materia medica.

Order 3. SPASMODIC AFFECTIONS. Spasmi.

395. *Tetanus. Symptoms.*—It is not often, in this country, that tetanus is met with to that malignant and frightful degree that it manifests in tropical climates. The first symptoms, we are told by authors who describe the malady from having been eye-witnesses to it, are a stiffness in the back of the neck, and a difficulty of swallowing; then a pain attacks the breast, which shoots through to the back and shoulders,—the jaws become locked, and the head is forced violently either forward or backward. Much convulsive movement also takes place in the abdominal muscles; the countenance becomes distorted; the tongue is thrust out of the mouth, and these symptoms, with others marking general perturbation, remit and recur for a longer or shorter time, till 'at length one universal spasm rushes upon the patient, and carries him off in its frightful embrace.'

Causes.—Mere heat, or sudden changes from the extremes of heat to cold, and vice versa, will sometimes of themselves be equal to the

production of tetanus; but for the most part these are mere circumstances of predisposition, and the excitant is some local injury,—more especially that of wounds in tendinous structure. The proximate cause has been recently considered a high state of inflammation in some portion, more particularly the upper portion, of the spinal cord. Others have considered the spinal affections, which are discoverable upon dissection at times, to be rather the effect of that violent impulse which is made upon these parts, and which thus brings the vessels of the theca into an inflammatory condition, than that the inflammation itself is primary and essential (see the introductory remarks to the present order).

Prognosis.—Highly unfavorable for the most part. If it occur merely from the heat of the climate, or general derangement, it may terminate favorably; but, when it is the consequence of lacerated tendinous wounds, it is seldom that life does not succumb under the virulence of the malady.

Treatment.—Opium, in exceedingly large quantities, seems to have been the only remedy hitherto discovered at all efficacious in meeting and conquering the terrific force of this frightful advent. A whole ounce of laudanum has been given in twenty-four hours, and indeed there need scarcely be any limit to its administration, as the convulsive affection seems in a manner to swallow it up, and prevent any of the common effects of the drug upon the frame. When lacerated wounds have produced the tetanus, these should be freely divided and laid open; and the wounds may be dressed with matters with which tincture of opium should be mixed; it has been said that dossils of lint, well imbued with laudanum, and put into wounds, will prove preventive of tetanus. Should worms or stomach derangements have ingendered the disorder, pretty considerable doses of the ol. terebinthinæ might be administered with advantage, and it will of course be at all times requisite to take cognizance of the condition of the stomach and bowels; but after all the round of all the known medicinals that, from analogy, might promise to be of some avail, we believe that no reliance is to be placed on any excepting very large doses of opium, continued till the abatement of the spasms.

396. *St. Vitus's dance.* Chorea.—Dr. Cullen's definition is so accurate that nothing need be added in the way of history.

Causes.—The predisposition to chorea seems to be constituted by a mobility of nerve. The exciting causes are irritations in the stomach and bowels, teething, mental affections, and imitation of others.

Distinctions.—Chorea has been said to bear about the same relation to genuine epilepsy that palsy of one side does to complete apoplexy,—and there is something in the analogy. There is, however, this essential and important difference between the two maladies of epilepsy and St. Vitus's dance, that the latter, however violent, is for the most part but temporary, and comparatively with epilepsy very seldom indeed fatal. Chorea, too, seems more influenced by physical remedies than epilepsy; and we have been as satisfied with the actual efficacy of medical management in this complaint as in almost any that could be named, which are in some measure of a chronic character.

Prognosis.—Seldom dangerous, unless the violent agitation fastens upon some vital part, and produces organic disease, such as hydrocephalus. We have never seen but one death from chorea, and then the disorder became hydrocephalic.

Treatment.—Purgatives and tonics are to be administered, one of the best of which is the nitrate of silver; but it is often found necessary to alternate this with the sulphate or oxide of zinc: cold bathing; sudden impression on the mind; this has occasionally both caused and cured chorea.

Epilepsy. Epilepsia.

Symptoms.—Epilepsy is derived from a Greek verb, επιλαμβανω, which signifies to seize upon, and the suddenness with which its attacks are for the most part made is the particular feature of the disorder from which its name is taken. In stating the more prominent symptoms of epilepsy it is perhaps scarcely necessary to observe, that the same variation of circumstances takes place in this as in every other malady that has a distinctive denomination, and that no one account will apply accurately to different epileptics, or can be considered in any other light than as a collective aggregate of the most ordinary occurrences.

The sudden fall of the patient to the ground is considered as the most essential characteristic of an epileptic fit, so much so indeed that the paroxysms of epilepsy have received the vulgar appellation of falling fits; frequently at the moment of the attack a shrill cry is uttered, and the limbs are soon agitated with violent convulsions; sometimes, in connexion with these general agitations, a fixed permanent spasm takes place in one or more of the muscles, and an epileptic is often observed to retain a firm grasp of any thing that he may have had in his hand immediately before the accession of the fit. The countenance exhibits for the most part a terrifying spectacle, from the violent contortions of the muscles of the face; the eyes become prominent and are fixed; sometimes, however, they are so distorted that scarcely any of the colored part of these organs is discernible; the hair often stands on end as in fright; in the great majority of instances saliva issues from the mouth as foam; and this is not seldom mixed with blood in consequence of the vessels of the tongue being wounded by the convulsive action of the jaws: the saliva that issues is at times extremely fetid, as is likewise the case with other excretions. In some instances the urine and semen are discharged involuntarily, and the former is thrown out, as with a jet, to a considerable distance. The contents of the bladder have been observed, it is said, in children, to form a jet of three feet.

Epileptic attacks are very often made without the intervention of any preparatory signs, or warnings of its approach; at other times the disorder is ushered in by antecedent symptoms, similar frequently to those which precede a paroxysm of apoplexy, such as pain in the head,

vertigo, obscure perception of surrounding objects, stammering in the speech, coldness of the extremities, nausea, and other signs of nervous derangement. One particular phenomenon sometimes precedes a confirmed fit of epilepsy, but of which we perhaps read more in authors than observe in practice, notwithstanding that by some it has been regarded as a sine quâ non in epilepsy, it is a sensation of a peculiar irritation commencing in some distant part of one of the extremities, and perceptibly directing its course towards the brain, before the general shock is effected. This feeling has been named the epileptic aura.

The length of time which a paroxysm of epilepsy lasts varies exceedingly; the average period has been stated to be from fifteen to twenty minutes; the return to the natural state is also made at very different times in different individuals, and is likewise very different in the fits of the same individual. Scarcely a vestige is often left of disorder when the patient shall have recovered from the violence of the fit, while in other cases a languor and general indisposition will remain for hours and even for days. The intervals likewise between the accessions is exceedingly various. Epileptic fits fully marked have been known to recur several times in the course of the same day; at other times weeks, months, or even years, shall elapse previously to the repetition of the disorder.

The lunar periods have been thought by some authors, and are generally conceived by the vulgar, to regulate the return of paroxysms; others state that they have never been able to trace with any certainty this supposed connexion, although they have watched the disorder with particular reference to this point.

By the protraction of the complaint, or very frequent recurrence of the paroxysms, the memory and intellectual faculties in general become much weakened in the majority of cases; and, when actual insanity supervenes upon a long continued epilepsy, the distemper is considered of so malignant and confirmed a nature that the public receptacles for the cure of the insane, close their doors against the admission of this kind of lunatics.

The disease in the severe form above described most commonly happens at the season of youth. The epilepsy of infants is for the most part of a much milder nature and remediable character; indeed the fits of childhood which by common consent are denominated epileptic, have often no determinate form or origin.

Causes.—Let the student remark the several causes cited in the nosology. Predisposition to epilepsy is often hereditary; the exciting causes are all those which derange the mobility of the nervous system; such as vehement emotions, affections, or passions. Terror is a common cause of epilepsy. The physical causes are those that exist in the brain, such as slow inflammation, or congestion; tumors, polypi; spiculæ of bone: abscess; hydrocephalus; or those that primarily affect other portions of the frame, such as irritations in the alimentary or intestinal canal, more especially worms; suppressed evacuations, as of the menstrual discharge; repelled eruptions of the surface; difficult and painful dentition. But to the question what is the proximate cause of epilepsy? it is difficult to give a satisfactory answer. If it be said that it is an overladen or overactive condition of the blood-vessels of the organ, it might be objected, why does not such plethora or irritation always occasion this particular form of the disease? Again, the phenomena connected with the sympathetic production of the complaint, as above alluded to, and the habitual occurrence of it when it is permanently fixed as a constitutional disorder, are against the notion of either plethora or vascular irritation being absolutely necessary to the production of epilepsy—though these conditions of the brain do unquestionably occur at times simultaneously with the occurrence of the fit.

Distinction.—The distinguishing features of epilepsy are convulsion of the limbs, in connexion with sopor, and the foaming at the mouth. See *Apoplexy*.

Prognosis.—When the malady depends upon cerebral conformation, or permanent disorder in the brain, it is incurable. It will sometimes leave the person that has been attacked before the age of puberty, at the time when the sexual characteristics appear. When the disorder is sympathetic, it for the most part yields with the yielding of the primary complaint. It often terminates in apoplexy, or madness, or idiotism. An intermittent fever or chronic eruption on the skin has been known to cure an epilepsy.

Treatment.—If it be symptomatic of worms, vermifuges are of course its remedies. If the fits are connected with manifestations of cerebral fulness of blood, bleeding must be enjoined; if, on the contrary, an asthenic condition of the system, and want of cerebral excitement, are the concomitants, stimulants, especially the carbonate of ammonia, are loudly called for; and the practitioner should ever bear in mind the active and passive states in which these convulsive disorders show themselves. The following enema has been recommended:

℞ Tinct. assafœtid. f. ℥ß.
Tinct. opii f. ʒi.
Aquæ f. ℥viij.
Fiat enema.

Take of tincture of assafœtida a fluid half ounce, tincture of opium a fluid drachm, water eight fluid ounces. Make an enema.

During the fit care must be taken to loosen every thing about the patient, especially his neckcloth, and buttons of his collar; thrusting a something, as a piece of wood, between the teeth, will prevent the tongue from being wounded, and is said to shorten the time of the fit. Dashing cold water over the face is sometimes proper and useful. It is always right, as in apoplexy, to let the head be rather high. In the permanent treatment, we must endeavour to strengthen the nervous system, when the disorder is the result of mobility, founded on weakness; the most powerful of the tonics, for effecting this purpose, are the oxide and sulphate of zinc, the medicinal preparations of copper, the nitrate of silver, and the vegetable bitters, or the Peruvian

bark. It will be found expedient often to vary and alternate these medicines, and sometimes advantage will be obtained by their combination.

℞ Argenti nitratis gr. i.
Conf. rosæ gr. v.
Fiat pilula: ter in die deglutienda.

Take of nitrate of silver one grain, confection of roses five grains. Make a pill, to be given three times a day.

℞ Zinci sulphatis gr. j.
Pilulæ galbani compositæ gr. ix.
Fiant pilulæ duæ: ter in die sumendæ.

Take of sulphate of zinc (white vitriol) one grain, compound galbanum pill nine grains. Make them into two pills; to be taken three times a day.

℞ Zinci oxydi gr. iv.
Extracti gentianæ ℈ß.
Fiant pilulæ tres: ter in die capiendæ.

Take of oxide of zinc four grains, extract of gentian ten grains. Make three pills; to be taken three times a day.

℞ Cupri ammoniati gr. ij.
Confectionis rosæ gr. v
Fiat pilula: ter in die exhibenda.

Take of ammoniated copper two grains, conserve of roses five grains. Make a pill; to be taken three times a day.

The sulphate of quinine will not be so likely to nauseate the stomach as the requisite quantities of bark in substance.

While administering these medicines, it will be necessary to attend to the alvine and other secretions, and, if any marks of plethora present themselves, these must be met by local, if not by general blood-letting, even at the time that we are persisting in our generally tonic plan of treatment.

It may be doubted whether much good is effected, in epileptic affections, by the class of medicinals that are called antispasmodic, such as castor, assafœtida, musk, ether, and others. The valerian, however, seems not only antispasmodic, but permanently tonic, to the nervous organisation; and, as such, especially applicable to convulsive and other affections, the origin of which is in pure debility of the sentient and motive powers.

℞ Rad. valerianæ incisæ ℥j.
Canellæ alb. cort. contus. ʒij.
Aquæ ferventis Oi.
Macera per horas duas, dein cola.

℞ Hujus colaturæ f. ʒxij.
Tinct. valerian ammon. f. ʒj.
Fiat haustus: ter in die sumendus.

Take of cut valerian root one ounce, canella alba bark bruised two drachms, boiling water one pint.

Digest for two hours, then strain.

Take of the strained liquor twelve fluid drachms, ammoniated tincture of valerian one fluid drachm. Make into a draught; to be taken three times a day.

The purgatives that are employed in epilepsy ought, for the most part, to consist of those which are warm and stimulating; and in case of the disease depending in females, as it sometimes does, upon uterine irregularities, the decoctum aloes compositum will be found especially serviceable. The dose is from a fluid half ounce to an ounce and a half.

Sea and cold bathing are sometimes beneficial. An emetic, or a large dose of opium, as in intermittent fever, just before the recurrence of the fit, is said to prevent or mitigate it; the attack, however, is, for the most part, too sudden to admit of these expedients.

Many are the reputed specifics in epilepsy, such as the viscus quercinus, or misletoe; the gratiola officinalis; the rhus radicans; the cicutaria, &c. But in the present day scepticism, respecting the virtues of these reputed remedies, increases upon us, and we are disposed to think nothing operative but what has either a manifest agency upon the secretions, or a decided influence in giving tone and energy to the nervous system.

The oleum terebinthinæ, as an antiepileptic, perhaps, came to be lauded on account of its virtue as an anthelmintic; and its continued employment, in doses of about thirty minims, twice a day, in peppermint-water, may prove positively beneficial, when the epileptic disorder is connected, in the way of cause, with intestinal irregularities. But of confirmed epilepsy, arising from hereditary conformation, permanent brain disease, or any other inherent and untangible source, if time may be looked to as a cure, medicine certainly cannot.

Change of climate, and habits of life, may occasionally have operated with radical and permanent benefit.

398. *Palpitation.* Palpitatio.—This arises from the same circumstances and causes as syncope, when it is not an organic affection. See *Syncope*.

Asthma.

Symptoms.—An attack of asthma is often preceded by drowsiness, pain in the head, and a feeling of flatulent fulness about the stomach, with a depression of spirits, and sluggish bowel. —At other times, the disorder, attended by the symptoms marked in the definition, seizes upon the patient at once: this is often in the night, after the first sleep; and it recurs nightly for some length of time. The patient has, for a time, a distressing sense of suffocation, occasioning him to rise from a horizontal to an upright posture, which, with the wheezing, and subsequent expectoration, are truly characteristic of this dreadful disorder. The expectoration generally comes on towards the approach of morning.

Causes.—In the hereditarily disposed, asthma will occur from almost any cause which in others create common derangement; exposure to cold or moisture; violent exercise; mental agitation; suppressed evacuation; receding exanthemata, or retrocedent gout; stomach, or hepatic, or bowel, or uterine, or renal irritation, will all, under predisposition, prove excitants of the disorder.

Distinctions.—It is distinguished from pulmonary inflammation, either of an ordinary or specific kind, by the periodical character of its attacks, the patient in the intervals being free

from disease, by the wheezing, and by the peculiar sense of suffocation. It is seldom too that asthma is attended by those pyrexial or febrile accompaniments that are found in truly inflammatory affections of the chest.

Prognosis.—Generally unfavorable, when confirmed; when it takes place in young persons, and is traceable to obvious causes, a recovery may be expected. Its fatal termination is, for the most part, by the induction of other diseases, such as organic affections of the heart, and hydrothorax. Sometimes, indeed, positive inflammation of the lungs will be the consequence of asthma.

Treatment.—In habits of much plethora and high action, blood-letting is required in the paroxysm; in taking away blood, however, we must recollect the spasmodic nature of the disorder, and its tendency to terminate in hydrothorax. Antispasmodics are often freely admissible, and combinations of these with anodynes prove useful. Assafœtida glysters may be thrown up the rectum.

℞ Spiritûs ætheris sulphurici compositi f. ʒj.
Tincturæ opii ♏vj.
Misturæ camphoræ f. ℥iß.
Fiat haustus.

Take of compound spirit of sulphuric ether a fluid drachm, tincture of opium six minims, camphorated mixture a fluid ounce and a half. Make them into a draught.

One of the most powerful agents, as adapted to the circumstance of asthma, is the stramonium.

℞ Extracti stramonii gr. ß.
Confectionis aromaticæ q. s.
Fiat pilula: ter in die sumenda.

Take of extract of stramonium half a grain, aromatic confection enough to form a pill. To be taken three times a day.

The belladonna, and aconitum, and digitalis, and conium, have been administered with the same intention.

Towards the close of the paroxysm, when expectoration is not free, let expectorant remedies be administered.

℞ Misturæ ammoniaci,
Aquæ puræ āā f. ʒvj.
Tinct. scillæ ♏x.
Syrupi tolutani f. ʒj.
Fiat haustus.

Take of ammoniacal mixture and water of each six fluid drachms, tincture of squill ten minims, syrup of tolu one fluid drachm. Make them into a draught.

The application of a blister to the chest is often highly useful. The bowels must be briskly acted on with the warm and aromatic purgatives; and both in the treatment and the prevention of asthma, but more especially in the latter, the state of the stomach, and first passage, must be sedulously attended to. Dr. Bree treats asthma as a stomach disorder; he cautiously confines the diet to easily digested materials, and gives carbonate of steel, soda, &c., to strengthen the fibres of the stomach, correct the acid fermentation, and alter the internal secretions. In this view, also, he recommends small doses of the mineral acids. Warm clothing is always necessary in asthma. Coffee is sometimes found to abate the violence of the disorder. Regular exercise, both of walking and horseback, should be enjoined: an assiduous care should be taken not to check perspiration. Change of air is often desirable; but there is great irregularity, and often inexplicably so, with regard to the appropriate kind of air for asthmatics; some being benefited by a warm, others by a cold atmosphere; some breathing best in a humid, some in a dry situation; some courting the vivifying air of an open country, others loving rather the smoky atmosphere of a large city. Issues are occasionally of service to old asthmas; and some are in the practice of giving an emetic just before the expected accession of the fit.

399. *Difficulty of Breathing.* Dyspnœa.—Dyspnœa is rather a symptom of other diseases than in itself a malady of a specific kind. Asthmatic and other impediments to free respiration are often obscure in their rationale; sometimes there seems to be a sort of spasmodic stricture in the bronchial cells, without inflammatory action on the one hand, or effusion of lymph, or mucus, or matter, on the other hand; and then the true spasmodic asthma is present; at other times the secretion or effusion is temporary, and the pituitous asthma is formed; then again it is permanent, and permanent difficulty of breathing, or dyspnœa, is produced. This dyspnœa may, indeed, be occasioned by other causes of a more extensive nature, such as adeps pressing upon the bronchiæ, or mal-conformation of the thoracic cavity; in the one case the remedy is obvious, in the other it must be obvious there is no remedy.

400. *Whooping cough.* Pertussis.

Symptoms.—Whooping-cough often exists with very little more than ordinary catarrhal symptoms for two or three weeks; the breathing, however, will generally be found to be more difficult and obstructed than in common cough; at length the whooping sound is heard, which is occasioned by the air rushing through the glottis with unusual force and rapidity, to make up, as it were, for the convulsive and frequently recurring expirations. After the fit or fits are over, a considerable quantity of mucus is brought up, by which the little patient is relieved from his distressing and suffocative sensations, and he returns to his play as if nothing had happened or was again to happen. Vomiting frequently terminates a violent paroxysm, and then, for the most part, the subject of the disorder expresses a great desire for food. But the peculiarity of the complaint is certainly this, that in the intervals of the fits there are no relics of the disorder, until, by the protraction of the malady, the individual becomes worn down, or bronchial inflammation, of a permanent kind, has taken place of the mere spasm by which, in the first instance, the distemper seems to be constituted.

Causes.—Specific contagion. Whether it may arise spontaneously, or whether, under epidemic peculiarities of the atmosphere, it may be made to supervene upon common catarrh, is a doubtful

and disputed point. Its proximate cause seems, as just intimated, to consist of spasm in the first instance, and congestion and inflammation in the course of time.

Distinctions.—The distinguishing peculiarities of the affection are the whooping noise, the complete cessation of the distressing feelings in the intervals of the fits, and the paroxysms ending in vomiting.

Prognosis.—When the disorder occurs after the child has got through dentition, when the strength seems but little impaired, and the tendency to pulmonary inflammation does not manifest itself, expectations of thorough recovery are well founded. The unfavorable concomitants are, early infancy, much appearance of pulmonary congestion; and the occurrence of convulsions; indeed, the bias of the disorder is often towards head affection in young children.

Treatment.—If inflammatory or congestive appearances manifest themselves, put leeches upon the chest or head. Give emetics of ipecacuan and antimony combined; let the bowels be kept free; meet the pyrexial irritation by saline diaphoretics, and the supersaturated liquor ammoniæ acetatis (that is, supersaturated with ammonia), should there be much appearance of sinking. Give hyoscyamus, and conium, and digitalis, and prussic acid, in conjunction or separately, when the cough seems purely spasmodic; occasionally change these from one to the other. When there is much difficulty of expectoration, add a little of the wine of ipecacuan, and the oxymel of squills, to the above antispasmodics. Correct the stomach acidities by carbonated soda or potass. A popular remedy for whooping-cough consists of salt of tartar and cochineal, and it is said to be very efficacious. Apply blisters to the chest, or the tartarite of antimony ointment, with opium. Rub the chest and neck with diluted tincture of cantharides; give small doses of this internally; and when the violence of the disorder is abated, debility only remaining, give tonics, such as Peruvian or Cascarilla bark, or small doses of the liquor arsenicalis. Above all, change of air, which is magically operative in whooping cough, in cases of protracted convalescence, and indeed, it sometimes will prove abundantly beneficial, even during the height and violence of the complaint.

401. *Water-brash.* Pyrosis.

Symptoms.—The fits of water-brash generally recur in the morning: there is sometimes an accompanying sensation, as if the stomach were drawn down towards the back. For the most part, as stated in the definition, the discharge is watery and thin, but it is sometimes glutinous and ropy. The pain is generally increased by an erect position of the body, which occasions the subject of the disorder to stoop forward.

Causes.—It appears to be a peculiar spasm of the stomach, affecting the secretions of the organ; it is sometimes brought on by poverty of diet, and mental anxiety. The lower classes of people, who live much upon food of a farinaceous kind, are very obnoxious to it. It often continues by habit for a long time.

Treatment.—Antispasmodics and absorbents; a plaster composed of equal parts of the emplastrum opii and emplastrum cumini to the epigastrium; the subnitrate of bismuth.

℞ Bismuthi subnitratis gr. vj.
Pulveris rhei, gr. iij.
Tragacanthæ, ℈ß.

Fiat pulvis; bis terve in die sumendus.

Take of the white oxide of bismuth six grains, of powdered rhubarb three grains, of gum tragacanth ten grains. Make them into a powder, to be taken three times a day.

The nux vomica may be tried in doses of five or six grains. Eggs boiled hard, and eaten pretty freely, have put a stop to obstinate pyrosis. The smoking or chewing of tobacco will likewise occasionally subdue it.

402. *Colic.* Colica.—Abdominal pain with a sense of twisting, especially about the navel; vomiting; constipated bowel. It is produced, first by spasm, second by the poison of lead, in which case we have what is called the painter's colic, marked by a gradual accession of the severer symptoms, with pains in the arms and back, the arms eventually become paralysed; third, by protracted costiveness; fourth, by acrid ingesta; fifth, by retention of the meconium in infants; sixth, by stricture in some part of the intestinal canal, occasioning windy collections and eructations; and seventh, by calculous concretions in the bowels.

Distinctions.—From enteritis, by the absence of pyrexia, by pressure in inflammation increasing, while in colicky spasm it sometimes diminishes pain, and by the irregular contraction in the abdominal muscles which has place in colic.

Prognosis.—Favorable when the pain remits or changes its situation; when there is a discharge of wind and fæces, followed by an abatement of symptoms. Unfavorable symptoms are violent fixed pain; obstinate costiveness; sudden cessation of the pain followed by more frequent hiccough, great watchfulness, delirium, syncope, cold sweats, weak tremulous pulse, the pulse becoming hard, and the pain, before relieved, now becoming increased by pressure; in fact, all the symptoms indicating the supervention of inflammation.

Treatment.—To be directed, of course, to its exciting cause. Sometimes it is necessary to have immediate recourse to powerful antispasmodics, whatever shall have been the source of the disorder. Warm fomentations are always admissible, and for the most part conspicuously serviceable; the warm bath; and when we wish for evacuations, and fail in producing them, dashing cold water upon the legs and abdomen, or causing the patient to stand with his naked feet on cold marble, will sometimes relax the spasm which thus obstinately retains the fæces. Give the croton oil, in doses of two or three drops, when common purgatives fail; rub the abdomen all over with castor oil; give large doses of castor oil internally, when the stomach will bear it. This last is especially applicable in the colica pictonum, which requires also small doses of calomel and opium combined, given for some time.

Warm bathing is exceedingly useful in colica pictonum; and in its chronic state, when little besides the paralysis of the arms remains, the use of the Bath waters proves of unequivocal efficacy.

In all cases of colic we should carefully watch the coming on of inflammatory symptoms; and it is partly because inflammation is so easily induced that we must, while using our antispasmodics freely, take especial care that we do not lock up fæcal, or calculous, or any other matter in the intestinal passages. The opiate confection is one of the best forms of administering opium in colicky pains; it is not so constringing as other preparations of this medicine, and its constipating tendency may be guarded against by tincture of rhubarb. Its dose may be a scruple.

The opiate confection deserves to be in more frequent use than it is in the general practice of medicine.

We have been principally indebted to Dr. Uwins and Dr. Hooper for the three or four last sections, having done very little more than add a few remarks on their histories and descriptions, and given a translation of their recipes. The two following sections on colica pictonum and worms we extract unaltered from Dr. Hooper's Vade Mecum.

403. *Of the colica pictonum.*—The colic induced by lead, is more obstinate, and longer protracted, than the same disease brought on from common causes; and frequently terminates in paralysis of the wrists and upper extremities.

Treatment.—Oleum ricini, often repeated, is most effectual in procuring stools, and, with fomentations and warm bath, generally removes the disorder in a few days; afterwards mercury united with opium, to excite slight salivation; alum; electricity; chalybeate and sulphureous waters; sinapis.

℞ Hydrargyri submuriatis gr. ¼.
Extracti opii gr. ß.
Confectionis rosæ q. s.
Fiat pilula; ter in die sumenda.

Take of calomel a quarter of a grain, opium half a grain, conserve of roses enough to form a pill, to be taken three times a day.

℞ Hydrargyri submuriatis gr. ¼.
Sulphureti antimonii præcipitati gr. ½.
Confectionis opii gr. v.
Fiat pilula; ter in die capienda.

Take of calomel a quarter of a grain, precipitate sulphuret of antimony half a grain, opiate confection five grains. Make them into a pill, to be taken three times a day.

℞ Aluminis purificati ℈ß.
Infusi rosæ f. ʒxij.
Syrupi ejusdem f. ʒj.
Fiat haustus; ter in die sumendus.

Take of purified alum ten grains, infusion of roses twelve fluid drachms, syrup of the same one fluid drachm. Make them into a draught, to be taken three times a day.

Colica pictonum is often productive of inflammation of the bowels and peritonæum, when the warm bath, general and local blood-letting, must be had recourse to.

WORMS.—The human primæ viæ are infested by five kinds of worms.

1. Ascaris vermicularis: the small white thread or maw-worm.

2. Ascaris lumbricoides: the lumbricus teres, or long round worm.

3. Trichuris: the long hair-tailed thread-worm.

4. Tænia osculis marginalibus: the solium, or tape-worm.

5. Tænia osculis superficialibus: the broad tape-worm.

The ascarides have usually their seat in the rectum; the lumbrici occupy the small intestines, and sometimes the stomach; the trichurides the cæcum; the tæniæ the whole tract of the intestines, more especially the ileum.

Worms mostly produce symptoms of colic, and very frequently other symptoms, as variable appetite; fœtid breath; picking of the nose; hardness and fulness of the belly; sensation of heat and itching in the anus; preternaturally red tongue, or alternately clean and covered with a white slimy mucus; grinding of the teeth during sleep; short dry cough; frequent slimy stools; emaciation; slow fever, with an evening exacerbation; irregular pulse; sometimes convulsion-fits.

Worms appear more frequently in those of a relaxed habit; those whose bowels contain a preternatural quantity of mucus or slimy matter; in those who live on vegetable food; in the dyspeptic; the eating of unripe fruit is a frequent cause of their production.

They are evolved from ovula that exist in the human body, and in no other situation. For further information on this subject, consult An Attempt to an Arrangement of human intestinal Worms, published by the author in the fifth volume of the Memoirs of the London Medical Society.

Of colica verminosa.—1. The most esteemed remedies against ascarides and trichurides are purgatives of the submuriate of mercury, scammony, aloes, rhubarb, spigelia, cowage, tin; also assafœtida, lime-water, tobacco.

℞ Hydrargyri submuriatis gr. ij—vj.
Pulveris rhabarbari ℈j.
Fiat pulvis ex melle sumendus.

Take of calomel from two to six grains, powder of rhubarb twenty grains. Make into a powder to be taken with honey.

℞ Scammoniæ gr. iij.
Hydrargyri submuriatis gr. ij.
Sacchari purificati gr. vj.
Fiat pulvis ex quovis vehiculo crasso sumendus.

Take of scammony three grains, calomel two grains, purified sugar six grains. Make them into a powder to be taken in any thick vehicle.

℞ Extracti aloes spicatæ,
Extracti tanacæti, āā ʒß.
Olei rutæ ♏ xij.
Fiant pilulæ xij. quarum sumat æger duas nocte maneque.

Take of extract of aloes and of tansey of each half a drachm, oil of rue twelve minims. Make the mass into twelve pills, of which two are to be taken night and morning.

℞ Radicis spigeliæ ʒvj.
Aquæ ferventis O j.
Macera per horas duas.

℞ Hujus infusionis f. ℥xij.
Tincturæ cardamomi f. ʒj.
Syrupi zingiberis f. ʒj.
Fiat haustus nocte maneque capiendus.

Take of Indian pink six drachms, boiling water a pint. Let them stand to infuse for two hours. Then take of this infusion twelve fluid drachms, of tincture of cardamoms and syrup of ginger of each one fluid drachm. Make them into a draught to be taken night and morning.

The dolichos pruriens, or cowage, is best prepared at the late Mr. Chamberlaine's, of Aylesbury Street, Clerkenwell, and sold with proper directions.

℞ Liquoris calcis O j.
Fiat enema omni nocte injiciendum.

Take of lime water a pint. Make an enema to be administered every night.

℞ Misturæ assafœtidæ f. ℥iij.
Lactis vaccini f. ℥v.
Fiat enema tertia quaque vesperi adhibendum.

Take of assafœtida mixture three fluid ounces, cow's milk five fluid ounces. Make an enema to be administered every third evening.

℞ Foliorum tabaci ʒß.
Aquæ ferventis f. ℥x.
Macera, et liquorem frigefactum cola pro enemate.

Take of tobacco leaves half a drachm, boiling water ten fluid drachms. Digest, and when the liquor is cold let it be injected into the rectum.

℞ Limaturæ stanni f. ℥j.
Electuarii e senna f. ℥ij.
Syrupi zingiberis q. s.
Fiat electuarium molle, de quo sumatur cochleare unum minimum quovis mane.

Take of filings of tin an ounce, lenitive electuary three ounces, syrup of ginger as much as necessary to make a soft electuary, of which a tea spoonful may be taken every morning.

℞ Camphoræ ʒj.
Olei olivæ f. ℥ij.
Solve pro enemate urgente ani prurigine adhibendum.

Take of camphor a drachm, olive oil two fluid ounces. Rub them together so as to dissolve the camphor, and let the solution be employed as an enema in case of violent itching at the anus.

A decoction of the geoffræa inermis, or cabbage-bark, is a remedy much used, according to Dr. Wright, in the West Indies.

2. Against the tæniæ most of the drastic purges before prescribed have been resorted to. Madame Noufer's remedy is occasionally used with success. She directs as follows:—

The day before the patient is to take the remedy he is to avoid all aliment after dinner, till about seven or eight o'clock at night, when he is to take a soup made thus:—

Take a pint and a half of water, two or three ounces of good fresh butter, and two ounces of bread cut in slices; add to this salt enough to season it, and then boil it over the fire to the consistence of panada.

About a quarter of an hour after this, she gives him a biscuit and a glass of white wine, either pure or mixed with water; she even gives water alone to those who have not been accustomed to wine. If the patient has not been to stool that day, or is naturally costive (which is not usual, however, with patients in this way), Madame Noufer directs the use of a clyster.

Take a handful of the leaves of mallows, and boil them in a sufficient quantity of water, mixing with it a little salt, and, when strained off, add two ounces of oil.

Early the next morning, about eight or nine hours after the supper, the patient takes the following specific:—

Take two or three drachms of the male fern, gathered in autumn, and reduced to a very fine powder, in four or six ounces of water distilled from fern, or the flowers of the lime-tree.

It will be right for the patient to drink two or three times of the same water, rinsing his glass with it, so that none of the powder may remain either in the glass or his mouth in bed; and, to avoid the nausea which this medicine sometimes occasions, he should chew lemon, or something else that is agreeable to him, or he may wash his mouth with whatever he likes, but he must be careful not to swallow any thing. He may likewise smell to vinegar, to check the sickness; but if, notwithstanding all his efforts, the nausea continues, and he is obliged to throw up the specific, it will be right for him to take a fresh dose of it as soon as the sickness is gone off, and then he should try to go to sleep. About two hours after this he must get up, and take the following:—

Take of the panacea of mercury fourteen times sublimed, and select resin of scammony, each ten grains, of fresh and good gamboge six or seven grains. Reduce each of these substances separately into a powder, and mix them with some conserve into a bolus.

This is to be taken at one or two different times, washing it down with one or two dishes of weak green tea, the patient walking afterwards about his chamber.

When the bolus begins to operate, the patient is desired to take a dish of the same tea occasionally, until the worm is expelled: then, and not before, Madame Noufer gives him broth or soup, and he is directed to dine as is usual after taking physic. After dinner he may either lie down or walk out, taking care to conduct himself discreetly, to eat little supper, and to avoid every thing that is not of easy digestion.

The panacea of mercury is the submuriate; and the male fern is the polypodium filix mas of Linnæus, and aspidium filix mas of Smith.

4. Turpentine has been given in some cases with success. In the year 1795 a letter was put into the hands of the author, from a medical gentleman in the East Indies, which contained an account of a large dose of the oil of turpentine having been swallowed by mistake, and which brought away several worms. In consequence of this, the oleum terebinthinæ was administered as an anthelmintic in the dose of from one drachm to an ounce to several patients with tæniæ; the result was equally uncertain with other purgatives. Of late its use has become more general. The best way to give it is

mingled with syrup, and to direct the patient to take some gruel, arrow-root, or sago, after it. It produces a slight vertigo, and a sense of warmth and heat in the œsophagus and stomach, like to that produced by a glass of brandy; but these are very transient. Three or four evacuations are mostly produced by half an ounce.

405. *Cholera.* Vomiting and purging.

Symptoms.—The characteristic symptom of this sometimes very severe malady is the combination of vomiting and purging of bilious matter, and when the disorder is violent there is extreme sinking and painful feeling about the epigastrium, with spasms of the legs as mentioned in the definition; very great exhaustion of powers; hurried fluttering pulse, heat, thirst, and oppressed respiration. When the attacks are made with malignant violence, a fatal termination is sometimes the consequence, and that within twenty-four hours from the first occurrence of the sickness. In this case death is preceded by cold clammy sweats, very great irregularity in the pulse, and very violent cramps in the legs; hiccough, too, for the most part, precedes death.

Causes.—This is a disorder of the autumnal season, and seems to be occasioned by an acrimony of the bile produced by the combination of heat and moisture, connected in its manifestation with the cold, which, in the autumnal season, often quickly succeeds to heat, and tends to increase the disposition to the internal direction of the secretions, by obstructing the vessels on the surface of the body, or interrupting the irregularity of cutaneous discharge. The autumnal fruits have been supposed to be one main cause of the disorder appearing in the autumnal season; and, as far as these are difficult of digestion (plumbs and cherries in particular), there may be some justice in the allegation; but we very often find persons who never taste fruit the subjects of these violent bilious attacks; and it should seem, as above intimated, that the malady is rather referrible to sudden changes in atmospheric temperature, to cold and damp nights succeeding to hot days, and probably to some sort of specific influence that this combination of heat, and cold, and moisture, may have upon the biliary secretion, in increasing its quantity and imparting to it acrimony. In the tropical climates cholera shows itself with a force and malignity of which we in this latitude know nothing but by history; and this circumstance is in favor of the principle we now intimate as the most probable one to which its source may be attributed.

Distinctions.—Diarrhœa often occurs with some violence from the mere acrimony and overflow of the bile, but if the discharges are not accompanied by vomiting the disorder is without the essential of cholera morbus. In colic, too, and other enteric affections, there is often on the other hand considerable vomiting, but then the bowels are costive, and the disease therefore is different from cholera.

Prognosis.—When the oppression and exhaustion are extreme we may anticipate an unfavorable termination. In this country, however, the disorder does not, as above stated, in the general way put on so much malignity of character and aspect, and if the interference of art be prompt and judicious, the malady usually terminates speedily and favorably.

Treatment.—We are for the most part told by authors that a great deal of diluent drink should be thrown into the stomach, such as barley water, thin water gruel, and linseed tea, in order to lessen the acrimony of the bile, or sheath the coats of the stomach against its morbid influence. We are a little doubtful, however, with regard to the theory upon which the stomach is thus ordered to be drenched, and in the general way should avoid the practice. Opium should be speedily given, and, if the stomach is too irritable to bear it, enemas may be administered of starch in which there is a considerable dose of tincture of opium. The cholera which we meet with in this country will be usually controlled by a grain of opium and a grain of calomel given in the form of a pill; and, whether it is on account of the specific influence which the calomel as mercury has upon the liver, or from any other cause, certain it is that its combination with opium will often occasion the latter to stay on the stomach and assist in subduing the violence of the vomiting. Five grains of blue pill, with a grain, or half a grain, of opium, may be employed with the same intention and effect. A small draught, in which from ten grains to a scruple of opiate confection is rubbed down with some mint water, will sometimes be received by the stomach in spite of its irritability. Warmth applied externally, in the way of fomentation, to the epigastrium and abdomen generally, will often prove very serviceable, and sometimes the discharge of bile will be checked by the application of a blister either to the epigastrium or the back. The external application of a liniment, in which tincture of opium is mixed, as in the following formula, may also be advisable in these and some other cases of irritable stomach; indeed, external applications are not perhaps used and appreciated to the extent they deserve.

℞ Linim. camphoræ comp. f. ℥iss.
Tinc. opii f. ʒij.

Fiat linim. in ventriculi regionem fricatione sæpe applicandum parvâ quantitate.

Take of compound camphor liniment a fluid ounce and a half, tincture of opium two fluid drachms. Make them into a liniment; a small quantity of which is to be rubbed on the stomach frequently.

When the extreme irritability of the stomach has somewhat abated, and from the first in ordinary cases, tincture of rhubarb may be administered in small quantities. The following formula will be found, in many cases of sickness which should hardly amount to the violence of cholera, to be exceedingly beneficial; indeed, we have passed season after season, and have had public establishments to take care of, without the necessity of much more in the way of an immediate medicinal for ventricular complaints of the kind now referred to.

℞ Tinct. rhei f. ʒiij.
Confect. opii gr. xv.
Aquæ menthæ sat. f. ℥iss.

Fiat haustus.

Take of tincture of rhubarb three fluid drachms, opiate confection fifteen grains, simple mint water a fluid ounce and a half. Make them into a draught.

In the extreme exhaustion of the violent cases of cholera fifteen grains of opiate confection mixed with the same quantity of aromatic confection, and eight or ten grains of subcarbonate of ammonia, rubbed down into a draught with water, will often prove signally beneficial.

We have just said that the cholera of Britain is a mild disease, in the majority of cases, compared with that which is met with in the Indies. Of the frightful force with which attacks of bilious disorder are made in the east, and of the rigorous measures required to meet and subdue them, an opinion may be formed by the following masterly account taken from the Study of Medicine by Dr. Mason Good.

The rapid or sudden fatality of the disease (the Indian cholera), in its severest onsets, is very singular. Even Sonnerat affirms, 'that the patient was frequently carried off in twenty-four hours.' But, in the later epidemy of 1817 and 1818, this term was wonderfully abridged. 'In the second, and very fatal visitation,' says Mr. Orton, 'of the epidemic experienced by Brigadier-general Pritzler's force, I am informed that vomiting, purging, and spasms were very frequently, in a great measure if not entirely absent: all the powers of the system failing at once, and death commonly ensuing in three or four hours from the attack.' Several instances were heard of at Hoogly, and other places, of natives being struck with the disease whilst walking in the open air; and who, having fallen down, retched a little, complained of vertigo, deafness, and blindness, and expired in a few minutes. Mr. Gordon gives a history of many cases of this kind. At Bellary, a tailor was attacked with what was supposed to be cholera, and instantly expired, with his work in his hands, and in the very attitude in which he was sitting.

The dissections in this presidency seem to have shown even a more extensive range of visceral effusion, congestion, and extravasation than those in Bengal. Not a single thoracic or abdominal organ was to be traced unmarked by vascular rupture, or turgescence of black-blood, or unstampt with some other morbid appearance; the stomach and liver, however, were chiefly affected, and the urinary bladder was always shrivelled. The blood, when drawn from the arm, was found to coagulate very loosely, and sometimes not at all: and the arterial and venous blood were of a like purple hue.

Of the dreadful spread and havoc of this cruel Asiatic scourge, we may form some idea, from the report to the Medical Board at Bombay, by George Ogilvy, esq., secretary. The population in this district alone is calculated at from 200,000 to 220,000; the total number of ascertained cases amounted to 15,945; giving a proportion of seven and a half per cent. Of these cases 1294 sick had been without receiving medicine, or medical aid; and there is reason to believe that of these every individual perished. Mr. Ogilvy, indeed, expressly asserts that it was not ascertained that any case had recovered in which medicine had not been administered: while it is gratifying to learn, on the other hand, that, among those who had received the advantages of the judicious and active plan concurrently pursued, the proportion of deaths was reduced to 6·6 per cent., an alarming mortality still, but a marvellous improvement upon the natural course of the disease. In other parts of India, indeed, the deaths, under the same plan of treatment, seem to have been still fewer: for Dr. Burrell, surgeon to the sixty-fifth regiment at Seroor, out of sixty cases, makes a return of only four deaths; and Mr. Craw, on the same station, asserts, that, on an early application for relief, the disease in his opinion 'is not fatal in more than one in 100 cases.'

The curative plan, pursued with so much success, consisted in bleeding, according to the strength of the patient; calomel in free doses of from fifteen to twenty grains in a dose; with one or two grains of opium, repeated, if necessary, every four, three, and in some cases every two hours, till the urgency of the symptoms abated: to these were added a liberal use of the most diffusible stimuli, as the spirit of nitric ether, ammonia, camphor, hot arrack-and-water, mixed with spices and sugar, camphor-mixture, essential oil of peppermint, the hot-bath, stimulant embrocations; and sometimes the antimonial powder in doses of five grains given in conjunction with the calomel.

We are informed of a fortunate blunder in one instance, capable of being laid hold of and applied with great practical advantage. 'By mistake, twenty grains of calomel and sixty minims of laudanum were given at an interval of less than half an hour. The patient was inclined to sleep; nothing more was done; and in two hours and a half he was as well as ever he was in his life.'

Many of the cases proved successful without the use of the lancet: but, from a return of Dr. Burrell, the hazard of omitting it, whenever blood could be made to flow, seems rather unjustifiable: for according to this return out of 100 patients eighty-eight were bled, and twelve not; of the former, two died, being one to forty-four; of the latter, eight, being two-thirds or nearly thirty to forty-four. It is altogether idle therefore to depend upon stimulants alone, and to boast of their power to subdue the disease without active evacuants in the beginning of the curative process, as Hufeland and other writers on the continent appear to have done, without a sufficient knowledge of the real nature of the disease; if, indeed, it be this species which they have undertaken to describe, of which there is great reason to doubt.

Of the remote cause of this extraordinary malady we know nothing. That it is an epidemy, and of a most malignant character, is unquestionable; but whether dependent upon an intemperament of the atmosphere, or upon specific contagion, is by no means ascertained. The first was the most obvious mode of accounting for it, and that which was earliest adopted; but by many practitioners it has been rejected, for the following reasons. The disease, instead of spreading from a centre to a circumference, or following the

course of the wind, or of the sun, or obeying any other meteorological power, marched by a chain of posts, often in direct opposition to all kinds of atmospherical influence, and in the immediate track of human intercourse. 'It prevailed,' observes Sir Gilbert Blane, in his remarks upon Mr. Corbyn's letter, 'to a degree equally violent at all seasons of the year: in regard to temperature, from 40° or 50° of Fahrenheit to 90° or 100°; in regard to moisture, during the continuance of almost incessant rain for months, to that dry state of the atmosphere which scarcely leaves a vestige of vegetation on the surface of the earth.' To which I may add, that it often fought its way in the very teeth of the most powerful monsoons, and left untouched various districts that bordered on its career, and whose less salubrious features seemed to invite an acquaintance with it. It appeared also and vanished in all the changes of the moon, and in all states of atmospheric electricity: and at sea as well as at land. Mr. Corbyn, indeed, gives an account of its having made an attack upon the Lascars of an Indiaman, in its passage from England to the Cape of Good Hope, in 1814; and that too in the month of January, when the weather was intensely cold.

It has, hence, by many pathologists been supposed to have been propagated by a specific contagion: and in support of such opinion they have endeavoured to show, that it appeared in no town or district where a direct communication had not been maintained with some place in which it was prevalent. In this endeavour, however, they do not seem to have been successful. Nor is it easy to reconcile the suddenness of its appearance and disappearance with the laws of contagion, so far as we are acquainted with them; a subject we shall have occasion to examine at large, when treating of fevers. Mr. Allardyce, surgeon to his majesty's thirty-fourth, informs us, that in this regiment the disease appeared on the 21st of September, and committed dreadful ravages before night. On the 25th it abated remarkably, and in three days more entirely vanished. In like manner, the severe attack which was experienced by the Bengal and Madras troops at Nagpore, occurred at the end of May 1818. On the 10th of June, the rains appeared with great violence, when the epidemy abated, and immediately afterwards ceased. Neither is the idea of a contagious propagation reconcileable with the escape of the great body of persons exposed to the influence of the disease, considering that, from its not being apprehended to be contagious, no means, as is usual in other cases, were employed to avoid the infection.

The state of the atmosphere, as described by Mr. Allardyce, did not differ materially from that in Nagpore. The disease made its attack in close and sultry weather, and vanished after thunder storms and heavy rains. But we can draw no conclusion from these phenomena; since it seems to have shown itself quite as frequently and fatally after a long succession of rain; and, as already observed, sometimes in very cold and dry weather. The remote cause, therefore, of this mysterious scourge remains yet to be ascertained, and affords further proof, if indeed proof were wanting, of our general inacquaintance with the nature and economy of epidemics.

With the exception of the plague, there is no epidemy on record that seems to have been so strikingly marked by violence and irregularity of action, and especially by a rapid exhaustion of living power; the patient, as we have seen, often expiring within twelve hours from the attack, and sometimes sooner.

The first characteristic feature that occurs to us, on a review of the disease, is the total absence of the bile from the whole range of the alimentary canal in every case, while this fluid was as generally found in abundance in the gall-bladder; and, perhaps, the next is, the turgid, and, in some instances, the ruptured state of the liver from the quantity of blood with which it was distended. The general battery of symptoms appears, therefore, to have been opened by a spasmodic constriction of the bile-ducts; for, without such an obstruction, we cannot account for an exclusion of all bile from the intestines. From this point, as from a centre, the spasmodic action seems to have spread in every direction, and under a clonic or entastic form to have seized upon almost every organ; preying with greater violence according to the greater degree of debility, and hence, perhaps, of irritability of the system; into which law, we are to resolve it, that the natives, supported by a less rich and nutritive diet than Europeans, suffered more severely, and died more frequently. The stomach and intestines, generally speaking, first participated in the spasm of the bile canals, and hence the griping pains, the nausea, and violent commotions, which spread from the one to the other.

In all cases of nausea, from whatever cause, we see the brain and the surface of the body peculiarly diminished in their energy; whence the skin, to the remotest extremities, collapses beneath a deadly chill, and the heart sinks with insupportable languor. In the ordinary course of sickness the nausea subsides, and the general organisation recovers its balance, or it terminates in full vomiting, which excites a universal re-action. And where any such re-action occurred, in the disease before us, it was hailed as a favorable change; and hence the wisdom of the stimulant plan so frequently had recourse to by the medical staff for the purpose of producing a revulsion. But, where this was not accomplished, the living power, feebly recruited from its fountain from the first, or not recruited at all, became exhausted in every organ apace, the strength failed, and hope gave way to despair. While the general mass of blood, thrown back by the contraction of the vessels of the surface upon the deeper and larger organs, produced effusion, congestion, and extravasation, wherever they yielded most readily; and hence chiefly in the liver, which in hot countries is almost always in a debilitated state. In the midst of these accumulated evils, the spastic diathesis, instead of being subdued or even checked, became, by the very resistence it met with, more forcible and aggravated. Every organ successively or simultaneously submitted to its torturing cramp; the heart

was fixed and incapable of propelling the blood through the arteries; the muscles of respiration were incapable of expansion, the lungs were collapsed, and suffocation was threatened every moment.

None of the natural secretions took place; the bladder was shrivelled and empty; the bile, while in the gall-bladder, became discolored and dark; there was no fluid, or only a morbid fluid, in the pericardium, and the intestines were no longer lubricated with the refreshing moisture of health. But, while these secretions were put a stop to, others took place in different organs from the mortal struggle of those organs themselves, and chiefly where the struggle was severest. And hence those morbid fluids, and other materials, exhibiting almost every degree of consistence, which were found in the intestinal canal, and often ejected by the mouth and anus; varying from the nature of chyle, thrown back perhaps, by a retrograde spasmodic action of the thoracic duct, to the nature of that mucous and unctuous matter which the intestines are sometimes capable of forming even under other circumstances.

I have said that the living power, during the whole of the melancholy contest, seems to have been recruited very feebly from its fountain, or not recruited at all. The latter appears to have been the case in the island of Ceylon, where the disease raged with even more violence than on the Indian continent, and the patient very frequently expired in twelve or fifteen hours from its attack. A dissection of those who perished thus early in this quarter has put us into possession of some interesting facts, varying in a few particulars from those that occurred on post-obit examinations in the island of Bombay, and which will, I trust, uphold me in making this remark. The brain was in these cases chiefly the congested organ, the liver sometimes appearing to have no congestion whatever; and hence the inactivity produced in the brain by the nauseating state of the stomach must have been greatly augmented by oppression. Consentaneous herewith, we are told by Dr. Davy, that, in some of the cases which he dissected in this region, there was a flaccidity of all the muscular parts, as in animals killed by electricity or hunted to death. There was also a tenderness of the muscular fibres; while antecedently to death, as in many of the Bombay cases, there was no difference in the color of the arterial and venous blood, and no instance of a buffy coat on the blood that was drawn; which in reality was so loose and uncoagulable that, when venæsection was necessary, the vessels were opened with the greatest caution from the difficulty of restraining the blood afterwards.

In all these cases there can be little doubt that the supply of the living power from the brain was spent profusely, and soon altogether exhausted: in some instances, indeed, nearly momentaneously; like the effects produced upon the animal frame by a stroke of lightning, a violent blow on the stomach, or any other accident that occasions instant death by a total and immediate discharge of the vital energy.

In other cases, the oppression on the brain, produced by congestion, seems to have put an end to the conflict before the living power had completely failed, and while it was still acting with irregular accumulation in various organs: for, in these, the muscles of the extremities, and even of the face and lower jaw, were observed to move in a convulsive manner, and sometimes to be drawn into tremulous knots, fifteen or even twenty minutes after death had closed the scene. So the heart of the traitor, when extirpated after he has been beheaded, from a like accumulation of sensorial power, has been seen to palpitate, and even to leap up for several times in succession after its removal from the pericardium.

Commonly, however, the living principle seems to have been exhausted more generally and progressively; and the muscles, and indeed most of the organs, freed from the tetanic power that at first constringed them, to have been gradually relaxed and flaccid: and hence that comparative absence of pain that occurred so frequently a short time before death, with the flow of a cold sweat over the surface of the body, and of bile into the smaller intestines.

I have thus endeavoured to follow up and explain the different symptoms of this complicated disease, many of which appear at first sight to be incongruous with each other and of difficult reconciliation. And we may hence see how well calculated the plan of treatment pursued by the different medical boards was to meet them, and may trace the ground of its success. The grand objects before them were: to equalize the flow of the living power; to counteract the spastic action so common to the irritable diathesis of hot countries; to guard against the danger of congestion in the vital organs; and to restore the natural secretions of the system. The great danger of congestion was guarded against by bleeding; spasm and irritability were opposed by powerful narcotics; and the full and repeated doses of calomel were admirably calculated to act upon the secernents and restore them to their proper functions, and especially when united, as was occasionally the case, and perhaps always ought to have been, with antimonials. All this was sometimes accomplished rapidly, and the disease ceased in a few hours. But if from the violence of the attack, or from any other cause, it could not be accomplished at all, such violence could not long be resisted; and the patient in a few hours, or at the utmost in two or three days, fell a prey to its fury.

We may also be enabled to see, from the general history before us, why the present species of cholera, or that accompanied with general spasmodic contractions, should occur more severely in the hotter climates of India, or indeed of any other torrid region, than in the more temperate ones of Europe. Cholera is peculiarly characterised by a tendency to spastic action: but hot climates have a peculiar tendency to excite a general spastic diathesis, and to develope this diathesis in some degree or other in all diseases; whence, more especially, the frequency of tetanus upon slight wounds of the extremities, or an exposure of them to sudden chills: and hence, from the co-operation of

these two causes, the graft of a spastic disease upon a spastic temperament, the effect must be of a highly multiplied aggravation. It is well known, however, that this spastic temperament, though common to such climates, is by no means equally common to every inhabitant: and hence again we see a predisposing cause existing in some cases, which does not exist in others, and are able to trace out something of the reason why the epidemy should not have been able to fasten upon every individual with equal ease.

It still remains, however, to be ascertained, besides inquiring into the nature of the remote cause, why this disease should have been so much more severe as well as so much more frequent within the last six or seven years, than in former periods; as also, why an affection of the liver, or of the bile-ducts, should be capable of exciting so extensive a chain of influence on the nervous, rather than on any other system.

Whilst revising this sheet for the press, Sir James M'Grigor has informed me, that the disease in the Mauritius did not appear till after the arrival of a ship on its coast from Ceylon, where the epidemy was raging; some of the crew of which were seized with it on their passage, though all were well at the time of sailing. As a single fact, this is not sufficient to prove contagion; but, in the present uncertainty of the subject, it is a fact worth treasuring in mind.'

406. *Diarrhœa.* Looseness.

' *Symptoms.*—This in some causes a sort of minor cholera, and according to its sources is or is not accompanied with much pain and irritation.

Causes.—These act either on the body generally, or upon the part or parts affected. Cold checking perspiration is a very common source of diarrhœa; mental agitation occasionally produces it. Dentition is a most frequent cause of looseness in the bowels, and sometimes metastasis of other complaints upon the internal membrane of the intestines, or upon the liver, will excite the disorder. Indigestion is a frequent source both of costiveness and looseness; indeed the former disease never exists to any extent, or lasts for any time, without thus in one way or other disordering the bowels. Sometimes, and indeed very frequently, and often when it has not been suspected, an erythematic inflammation of the mucous membrane of the bowels will be the occasion of diarrhœa: indeed a degree of the same affection which when more violent or confirmed will arrest secretion, causes constipation and becomes positive enteritis. In many cases a mere superabundance of bile will be productive of the malady, and occasionally a deficiency of that secretion will be followed by looseness.

Distinctions.—When the complaint is merely looseness, and is not attended with the discharge of hard scybalous fæces mixed with blood and mucus, and exciting tenesmus, it is positively and properly diarrhœa from whatever cause originating. To the disease, in the form just mentioned, we should apply the term dysentery.

Prognosis.—Diarrhœa if judiciously managed usually terminates well; if imprudently interfered with, dysenteric and inflammatory ailment may be the result, and the malady may then become tedious, intractable, and dangerous. See *Dysentery.*

Treatment.—The management of diarrhœa demands considerable attention as to its exciting and proximate cause. A gentle emetic will sometimes prove its best remedy when it shall have been excited by any thing of an irritating nature taken into the stomach; and even some old diarrhœas, which continue from habit, will be best counteracted by the administration of an ipecacuan emetic, which breaks into the series of morbid action constituting the complaint. When obstructed perspiration has produced the complaint, small doses of antimony and opium or ipecacuan and opium, will be its best remedies; to this last medicine the blue pill or very small doses of calomel may be added.

℞ Pulv. ipecac. comp. gr. v.
Hydrarg. submur. gr. ß.
Syrupi aut. mucilag. acaciæ q. s.
Fiat pil.: bis terve in die sumenda.

Take of compound powder of ipecacuan or Dover's powder five grains, calomel half a grain. Make them into a pill with mucilage or syrup; one to be taken two or three times a day.

When the diarrhœa seems merely to proceed from a laxity of the intestines, or their exhalant vessels, astringents will be called for, such as kino catechu, alum, or logwood.

℞ Tinct. catechu f. ʒi.
Aquæ cinnam. f. ℥iß.
Fiat haustus.

Take of tincture of catechu one fluid drachm, cinnamon water a fluid ounce and a half. Make them into a draught; or a fluid drachm of tincture of kino may be used in place of the catechu.

The chalk mixture, (mist cretæ of the pharmacopœia,) is an excellent medicine for a diarrhœa connected with acidity; and it is therefore a very useful formula for children's complaints; in these, however, we must be careful to give either small doses of calomel or hydrarg. cum creta; or, where much intestinal irritation is present, castor oil, in order to prevent the cretaceous medicine from proving too precipitately astringent or absorbent; for, although it may be often necessary to check the diarrhœa of infants, we must be cautious against doing it too hastily or completely, since it is often the consequence of nature's efforts to lessen the general or local irritation, which without this induced looseness might prove considerable and fearful. Where much pain is attendant upon diarrhœa, the opiate confection, as just advised under the head of cholera, will often effect a good deal of benefit; and it may be combined with still smaller doses of tincture of rhubarb, than there mentioned. The aqua calcis, taken in the dose of a few ounces with an equal part of milk, is recommended occasionally in protracted disorders of the bowels. When there is a tendency to dysenteric irritation, the simauroba bark in infusion with a small quantity of tincture of rhubarb may be administered. In the treatment of all kinds and forms and degrees of diarrhœa, warmth to the external surface, and to the feet especially, is demanded. Opiate liniments as advised under the head of cholera, or

in long standing cases opium and antimony to the surface in the form of ointment, may be adopted. When there is reason to suspect that the villous coat of the intestines has become the seat of small ulcerations, very small doses of calomel and opium, say a quarter of a grain of each, will be useful; and with this plan may be conjoined the administration of small doses, likewise of the copaiba balsam. Ten minims or fifteen taken two or three times a day, rubbed down with mucilage of acacia or yolk of egg.

407. *Diabetes.*

Symptoms.—Dryness and harshness of the skin, emaciation, weariness and indisposition to exertion, constipated bowel, urgent thirst, frequently a voracious appetite, with œdematous swellings of the ancles, and febrile irritation of a hectic character, are the usual symptoms of diabetes, beside its main characteristic, that of a large flow of urine, which is sweet to the taste, and has the odor of hay. There is also, for the most part, when the disease has been of long standing, an excoriation at the extremity of the penis. Of true diabetes (or diabetes mellitus, as it has been called to distinguish it from the complaints in which, as in the hysteric disease, there is a large flow of limpid urine), it is necessary to remark this hay-like smell in the urine, which is sometimes so marked as to be discoverable in the odor of the patient's body. Dr. Latham, who has written on diabetes, mentions this particular, and in a very candid way. He tells us that a patient called upon him, for whom, after having made some enquiries, he prescribed some medicine, under the notion of the patient being a mere dyspeptic; but, as he turned from him to go out of the room, this peculiar odor struck him as proceeding from the man's body; he recalled him in consequence, renewed his investigations with this clue to guide him, and found the individual laboring under a confirmed diabetes.

Causes.—A long course of diuretic medicine has been said to produce diabetes; it is for the most part, however, brought on by poor living, accompanied by spirituous liquors. It is more common in Scotland, and in the north of Ireland, where the poorer class of people live principally upon oats or potatoes, than it is with us. The water brash is likewise, as we have said, more common under these circumstances and localities, and an analogy has indeed been supposed between these two diseases. Occasionally the disorder is produced by exposure to cold, or brought on by mental anxiety; and sometimes its occurrence does not seem at all traceable to any circumstance of obvious excitation.

In respect to the proximate cause of the malady, or the actual condition of organs as its procuring cause, opinion differs. Some have supposed it to have particular reference to the lymphatic system; others have traced it to some morbid state or action of the liver. The stomach theorists have referred it to defective digestion and assimilation: while others have looked upon it as a depraved condition in the secretory power of the kidney. There are difficulties attendant upon all these hypotheses. Certain it is that dissections of those who have died of diabetes have usually shown the kidneys to be considerably affected; but whether this altered structure, and probably, by consequence, altered action, is the result of the malady, or its primary circumstance and absolute essence, does not seem very easy to settle. Then, again, the digestive and assimilating organs would seem to be implicated, on account of the extreme emaciation; but those pathologists who maintain that the disorder is one of the kidneys, and of the kidneys alone, remark that the emaciation is to be accounted for by the discharge of so much saccharine matter daily; and they urge that the stomach, the liver, the pancreas, and the spleen, are found for the most part in a healthy state, as far as structure is concerned, while, on the other hand, the kidneys are highly disorganised, sometimes exhibiting a high measure of vascularity, at other times much enlarged, and of a paler color than natural. It should be observed that the urine of a diabetic patient is not merely different from that of a healthy individual in thus being laden with sugar, but that it is at the same time destitute of the urea and ammoniacal and earthy phosphates that are found as ingredients in healthy urine.

Prognosis.—Very unfavorable. It may indeed be doubted whether a confirmed case of diabetes, that is, one which had existed for any considerable length of time, was ever radically and permanently cured. We remember some remarkable cases in the Edinburgh Infirmary, which were under the care of Dr. Hope, at that time clinical professor, and two of which were dismissed as cured, and their cure deemed manifestations of the good resulting from Dr. Rollo's plan of treatment, which we are immediately to mention. These two individuals returned soon to the infirmary, there died of diabetes, and dissection proved the kidneys in a high state of disorganisation. And we are told by Dr. Uwins, in his recently published work on disorders connected with indigestion, that he was favored with a communication some time since, from Dr. Buxton, to the following effect:—that he, Dr. B., had used the meat diet in five instances of confirmed diabetes; that he had found a rapid, a decided, and a beneficial effect in all. But that he had not known it cure in one example. 'All the patients,' he says, 'who employed this meat diet, soon became fatter and stronger, and made less water materially, and that of a less diabetic quality than before, and the amendment appeared most conspicuous in the worst cases; but the disorder ultimately proved fatal in all.'

Treatment.—Diabetes, like hydrophobia, has been endeavoured to be subdued by almost all the remedial plans which ingenuity could devise, or mere empirical feeling suggest. Diaphoretics have been employed with the very natural expectation of possible good, by diverting from the kidney to the surface of the body. Astringents have been tried, and tonics, and chalybeates, under the notion of restoring tone to the kidneys and the organs of assimilation. Large doses of opium have been thought of, and experimented upon, and this in some instances with decided effect of a temporary kind. The tincture of cantharides, from the specific influence which this medicine has upon the kidneys, has been un-

availingly used. Horse-exercise, daily friction of the surface, and rubbing the whole exterior of the body over with oil, under the impression that this might prevent the cutaneous absorbent from taking in moisture from the atmosphere. Large blood-lettings, in order to abate the conjectured inflammation of a chronic kind going on in the kidneys; the warm balsams, more especially the copaiba, from the known effect that these substances have upon the urinary organs; and, lastly, a complete abstinence from all vegetable diet and spirituous liquor, and putting the patient entirely and exclusively upon meat as food, and at the same time giving hepatised ammonia, or carbonate of ammonia as medicine, have all been tried, and almost all of them with immediate and temporary, but not, we fear, with radical and permanent, benefit.

'We are informed, however, by Dr. Ferrier, that he has actually cured three confirmed cases of diabetes by a combination of cinchona, uva ursi and opium, taken three times a day, in the proportion of a scruple of each of the former to half a grain of the latter; and that, from the great success he had met with from this medicine, he found it unnecessary to try Dr. Rollo's plan. The doses were taken with lime water, which was also directed for the patient's common drink;' and which probably might have had a very considerable share in effecting the recovery.

Dr. Rollo's plan, beside enjoining a thorough abstinence from vegetables, was that of administering hepatised ammonia in doses of three or four drops, gradually increased to the production of giddiness, or pills containing about four grains of the subcarbonate of ammonia, to be given about twelve in the day; the skin is to be at the same time anointed with prepared lard; at night antimonial wine, with opium, is to be given; an ulceration of about the size of half-a-crown to be formed over the region of each kidney, and the bowels to be kept free by aloes and soap.

[*Note.*—We might here mention several other changes which the urine undergoes in its chemical composition and essential characters, particularly in reference to its proportionate quantity of urea: but as this subject is at present undergoing minute investigation by the labors of animal chemists, more especially by Dr. Prout, we have thought it better to defer the more particular notice and discussion of these points, till we come to speak more specifically and particularly of the composition of urine, in the article PHYSIOLOGY. Its chemical analysis is also examined under the head of *Urine*, in the article CHEMISTRY.

408. *Hysteria.* Hysteric disease.

Symptoms.—The definition is very accurate in respect of the main symptoms, but hysteria brings in its train such a numerous assemblage of symptoms, that to describe them would be to go almost the whole round of sympathetic, or, as they have been termed, simulative or mimositic maladies. The suffocative feel noticed in the description is often accompanied by a hurried or oppressed respiration, by distressing flatulence, and sometimes a feeling as if, could the pent-up wind be removed or expelled, every thing would go on well—the fear of death is remarkably characteristic of the hysteric disorder in its heigh. of manifestation, and the patient does often for a time lose consciousness, and to bystanders the appearance of life. On the day previous to penning this account, we have seen an hysteric patient, who had just recovered from one of these fits of syncope, and who described his sensations (for in this case the patient is a male) as highly distressing, and scarcely bearable during the progress of recovery. Shedding tears is remarkably characteristic of hysteria, and often gives much temporary relief to the sufferer.

Causes.—Nervous mobility is the predisposing cause of hysteria; and it is excited by all causes of irregularity, such as irritation from undigested food or from worms; alternations of temperature; crowded heated rooms; late hours; mental agitation; a diet either immoderately full, or too abstemious: some indeed talk of it as they do of every thing else as the result of irritation in the digestive organs exclusively; but we often see persons the subjects of the affection who are exceedingly regular in respect of diet, never experience any inconvenience from their meals, and are altogether without any manifestation of digestive disturbance. That the cerebral and sympathetic nerves are affected is obvious enough, but then it is not the stomach or its appendages that in these cases are implicated, except in a secondary and incidental manner. The ancients used to imagine the seat of the disorder to be the womb, and the globus hystericus, or suffocating ball, or sensation as if of a ball rising up in the throat, or more properly speaking the wind-pipe, was supposed to be an actual something rising from the womb—hence the name hysteria; but this idea is of course in the present day abandoned, although the disorder itself has very often a most manifest connexion, sometimes primary and sometimes in a secondary incidental way, with uterine conditions.

Prognosis.—For the most part favorable, unless when it depends upon some organic affection, as an inflamed or otherwise disordered brain; and, even then, it is not from the hysteria, however violent, that danger is to be apprehended, but from those affections which may have produced it.

Distinctions.—Epilepsy and hysteria are nearly allied; but the latter, even in its most violent forms, is without the foaming at the mouth and horrible convulsions characteristic of the former, while an epileptic has not that feeling of suffocation, or globus hystericus, which the hysteric subject has. Hysteria too is usually a disorder of females, though not as we have just said invariably.

Treatment.—Ascertain whether the disorder is sympathetic upon stomach or bowel, or uterine irritation, and if so, give purgatives and anthelmentics. If there be much plethoric fulness, and especially if the mobility of the system seem to have connexion, with fulness about the blood-vessels of the head, bleed from the arm, or apply leeches to the temples, or behind the ears. If a foul stomach is suspected, an emetic may be administered. In cases of costiveness, Dr. Thomas tells us that he has seen very speedy

and effectual relief obtained by administering the following enema:—

℞ Ol. terebinth, f. ʒiij.
Mucilag. acac. f. ʒß.

Misceantur benè simul in mortario et adde decocti avenæ, f. ℥xi.

Fiat enema.

Take of oil of turpentine three fluid drachms, mucilage of acacia half an ounce. Mix them well together in a mortar, and add thin gruel eleven ounces, for a clyster.

Antispasmodics may be given by the mouth, as soon as the patient is found capable of swallowing, but perhaps there is not so much to be expected from this class of medicinals as some imagine. One of the most useful medicinals of the nervous class appears to us to be valerian, which may be administered in the form of the ammoniated tincture, a tea-spoonful two or three times a day, or given as an infusion, in the proportion of half an ounce of the root to a pint of boiling water, and a wine glassful of this infusion taken two or three times a day.

When dyspeptic symptoms are present, especially should there be an accompanying acidity, the combination of magnesia and ammonia, as mentioned under gout, may prove of great service.

When it has been ascertained that merely morbid sensibility, and consequent mobility of the nervous system, is in fault, the metallic tonics may be administered; and one of the best is the nitras argenti, which may be commenced in doses of half a grain two or three times a day, and carried up to the extent of two or three grains. The oxides and sulphate of zinc, and the ammoniated copper, or ammoniated iron, may also be administered with the same view of lessening the sensibility and mobility of the nerves.

We have all along spoken of those symptoms that are common to the hysteric form of disease as simulative of formidable affection, rather than in themselves formidable; they are in common language nervous; and, although as real to the sufferer as those attendant upon organic disorder, are nevertheless essentially different, and require to be recognised as such by the practitioner. In a work recently published on nervous and digestive derangements, one section is devoted to the prominent marks of distinction between those affections which have most to do with the nerves, and those which rather implicate other parts of the frame, and we cannot have a better opportunity than the one now afforded us, of incorporating the section of the work alluded to in this article.

The maladies, says the author from whom we extract, which have been the subject of disquisition in the preceding pages are those, for the most part, of the sympathetic kind, as opposed to actual or structural disorders; and it may not be improper to add a cursory remark or two to those which have already been made respecting the particular features of distinction traceable between affections which are thus rather nervous than organic, or which are disorders of action rather than disorders of structure.

One of the most prominent circumstances of distinction between the one and the other may be taken from the pulse; for, in the fugacious and simulative affection, you will not find the arterial beats of that uniform and steady quickness which is characteristic of topical disturbance influencing the general frame. It is curious, indeed, to observe how the pulse of a nervous patient shall vary with varying circumstances. I have just seen a lady in the Kent Road, about whom there was some little reason for hesitation as to the extent to which the liver might have become implicated in the general derangement that was pervading the system: I felt her pulse, and found it, at my first coming into the room, quick and irritable; but, as it wanted that peculiar hardness or wiriness of character that marks topical inflammation, I hoped that, when the patient should become a little familiarised to the formidable appearance of two medical men standing by her bed-side, the temporary ruffle of the circulation would subside; and the event proved me to be right in my anticipations. I left the person in question with a pulse beating fifteen strokes in a minute less than when I first felt them; and I left her with a feeling, in a great measure founded upon the particular referred to, that although there was some measure of liver disease, it was not so formidable and extensive as I should have inferred it to be had the pulsations continued, from the first to the last, of a uniform celerity.

It is a curious fact that, when an actual affection of an organ takes place, the individual who is the subject of it often becomes less nervous, as it is called, or timid and apprehensive, than he was before; and the quickness of the pulse, which forms one of the characteristics of the new disorder, is not by any means regulated, as it was before, by the feelings and fears of the affected; and in this case there will be none of that momentary hurry and eventual calmness that, in the way just intimated, marks the mimositic as opposed to the real disorder. The term, by the way, real disorder, it is hardly proper to employ; for the malady is as actually existent in one case as it is in the other; and that physician knows very little of the laws which regulate the sentient organisation, who shall consider an ailment a matter of fancy, because it has no tangible essence or structural character.

With celerity there is, for the most part, a hardness of pulse when the blood-vessels are more engaged than the nerves, or when the general irritation is an index of some local disturbance of an inflammatory or irritative nature. This change in the pulsations, from a healthy condition, is indeed scarcely recognised by some physicians; and the late Dr. Heberden used to avow his carelessness about pulse beyond the mere number of its beats. 'If your patient,' says the author just named, 'has a pulse which regularly beats more than 100 in a minute, I should infer, that the affection of which he is the subject is somewhat dangerous; but I cannot go along with some individuals who talk of this and of that kind of pulsation as indicating the kind and measure of disorder.'

Others, again, profess an almost total disregard of number, and confine their observations,

and deduce their inferences, from mode almost alone. My own opinion on this head is intermediate; and although I consider the kind of pulsation an important point of recognition, and although I can find topical and inflammatory affection attended with hardness as well as celerity, and the more symptomatic and fugacious disorder without this same wiry character; yet I must confess that I cannot follow some of my professional brethren in all their apparent nicety of observation. In this respect, however, there is confessedly a good deal of difference as to tact. The late Dr. Gregory, of Edinburgh, used, I recollect, to say in his lectures, that he could seldom detect the fluctuation of dropsy which was so evident to others who might be in attendance with him; and we must, therefore, ascribe the difference of sentiment with regard to pulse, in a great measure, to the varied power of the individual of perceiving the varieties. At the same time, some may probably affect to have, or cheat themselves into the supposition of having, more delicacy of perception than is positively the case, —just as some would profess to feel, or fancy they felt, more pleasure in musical sounds than they actually do, merely because the want of the pleasure might be thought to imply a general deficiency of sentiment or taste.

The state of the spirits is another circumstance which will materially assist the decision, when assistance is wanted to judge between functional and organic disturbance. Those who have much fear about them have, for the most part, less cause for fear; and, when individuals tell you that they feel a presentiment that they shall die of disease in the lungs or the heart, you may generally conclude that their gastronymic system of nerves requires more correction than the condition of the organ about which their apprehensions are so much upon the alert. I have already, indeed, intimated, that, with the coming on of organic malady, a firmness and fearlessness of mind very frequently accompanies it. The late Dr. Reid, in his essays on nervous affections, tells of 'a lady who had, for a long time, been a miserable victim to the vapors, but who was completely cured of this complaint by the supervening of another which was more immediately alarming, and which precluded, indeed, the possibility of much longer life. No sooner,' continues the narrator, 'was the new disease ascertained to be an aneurism of the aorta, and the necessary result of that complaint was explained to her, than all her nervous feelings vanished, and she even bore the announcement of her inevitable fate with calmness. Hypochondriasis,' he adds, 'may often thank calamity for its cure.'

The countenance, in general, of a person laboring under organic disorder, is very different from one whose complaint is merely simulative or sympathetic; and the difference, like that of the pulse and the spirits, principally consists of the greater permanency and steadiness, as it were, of alteration from the physiognomy of health in the one case than in the other. There is, in the subject of organic disease, a continued sharpness and fixedness of feature which is very observable, and which the merely nervous patient is without; and when the stomach, but more especially the liver, happens to be the residence of the organic disorder, this fixed cast of countenance is accompanied by a peculiar anxiety of expression, or rather perhaps, I should say, of despondent indication. The term anxiety should rather apply to the physiognomy of a person with merely sympathetic malady; but then it is changed with the changing feelings that pass through his mind. I think it likely enough that an observant spectator would have perceived a marked change in the marked countenance of the late ruler of France, from the time that the general perturbation, of which he was the subject, resolved itself into a fixed point, and he became the subject of a topical and organic complaint.

It should be remarked that, when dyspeptic conditions are the occasion of the disorder, the precise nature of which we are desirous to learn, there is often a muddiness or dirtiness, as it were, of the skin, owing to the secretions of the surface being in sympathetic connexion with what is going on in the interior. Dr. Saunders, I think, in his treatise on liver complaints, speaks of this condition of the surface as peculiar to the dyspeptic or hypochondriac, who feels as if his skin constantly required washing; but this is a very different condition of the surface from that which is the indication of organic malady, accompanied by the sharpness and fixedness of feature just alluded to.

Emaciation, for the most part, accompanies organic malady, more especially if the organ affected be connected at all with the assimilating process; but, even in pulmonary affection, you find the patient sensibly losing his flesh and strength, while he himself is less sensible of the change than the hypochondriac sufferer, who feels himself rapidly wearing away, and is surprised that the change is not so observable to by-standers as he should suppose it would be.

When perspirations accompany fixed and organic disorder, they are more regular in their recurrence; they assume more of the hectic shape; they break out in the morning, and are, for the most part, rather confined to the upper part of the body; they are of a colliquative cast, as it is called; that is, they seem as if the frame were melting away under them, while the perspirations of the sympathetic complainant, although often profuse, are not so steady with respect to time, not so certain as to the part of the body upon which they break out, nor of so melting or dissolving a character. This distinction, indeed, more strictly applies to pulmonary affection; but it may be extended, with some qualification, to many others.

The pains of organic and sympathetic disease are remarkably different; and the difference relates partly to the locality of the affection, and partly to the state of nervous susceptibility of the patient. When the substance of an organ is implicated, and is wearing away under the malign influence of structural malady, the individual shall, at times, be scarcely conscious of pain at all, while the pain produced by nervous susceptibility, being called into actual consciousness, will prove, though perhaps transient, while it does last, comparatively severe.

The shivers, or rather rigors, which accompany disease, are very different in their aspect and character, as they shall be the indices of nervous or inflammatory affection. In the former case they will be fugacious and uncertain; in the latter fixed and regular.

Flatulent feelings and expulsions of wind are remarkably characteristic of nervous or sympathetic disorder; of the inflammatory or organic they are much less so. We may not, perhaps, subscribe to the medical axiom, ubi flatus nulla inflammatio; but, for the most part, where there is much of flatus, there is little of formidable disease.

When the seat of the disorder may be such as that you can make pressure on it with your hand, you will often find merely spasmodic or nervous ailment mitigated by the pressure; while if inflammation be going on, however slow and insidious, the patient's countenance, though he may not wish to acknowledge it, indicates that you occasion pain by the pressure. This is especially observable when our investigations are directed to the existence or not of liver affection, for here we press upon substance uninterfered with by bony parietes. In the case of chest affection, we must be guided by general distinctions, occasionally assisted by the ear, the ear itself being assisted by the stethoscopical instrument lately invented by our ingenious neighbours, the French, and brought into considerable use in this country. Although a little over forty I hope I am still young enough to listen to any suggestions by which a promise is made of forwarding the progress of medical science; and I do not feel inclined to deny, that the naked ear may be thus occasionally assisted by this artificial method of concentrating and conveying sound: but after all the ear is of much less use to us in medical investigation than the eye and the touch; and I am inclined to think that some of the boasted stethoscopical discoveries are like the salt on the bird's tail,—not made, till you have pretty well made them out by other means.

In a word, the sympathetic, or nervous, or mimositic patient, is always ready with his complaints: he will tell you of feelings about his eyes, of ringing in his ears, of pain in all parts of the head; and from the head he will traverse, with his bewailings, the whole topography of his body down, literarily ad calcem; he will call his physician back, after having detained him some half hour or longer, to add to his catalogue of miserable items, or to ask 'what he shall eat, or what he shall drink, or wherewithal he shall be clothed;' while, on the contrary, you are often obliged to force from the other individual what you do get in the way of information, and he is quite as glad as is the medical attendant when the time of the visit is over.

Hydrophobia. Canine madness; dread of water.

Symptoms.—A dread of water is perhaps rather erroneously considered as a characteristic of this dreadful malady; for there is no other fear of it than that which arises from the patient's finding himself incapable of swallowing it, without producing most distressing convulsions about the pharynx; the mere sight indeed, or even the hearing of water dropped, will occasionally bring on this horror and dread; but then it is produced almost involuntarily and necessarily from the recollection of previous suffering. The commencement of the disease is attended with extreme anxiety and general timidity, accompanied by a sense of suffocation, by intolerance of light and sound, by a secretion sometimes of saliva from the mouth, and by a remarkable susceptibility to the slightest motion or agitation of the surrounding air. Epilepsy and very violent hysteria are the diseases which more resemble hydrophobia than any thing else; it is not long since that we witnessed an extreme case of the latter disease which so much simulated hydrophobia, as to lead to the suspicion that the subject had been bitten by a rabid animal. It was in the last mentioned particular that the resemblance was so near, that, namely, of extraordinary agitation produced by the slightest agitation of the air about the patient. Towards the close of hydrophobia more frightful manifestations are presented, and the subject of it often dies within twenty-four or forty-eight hours from the attack.

Causes.—It should appear that the disease may arise spontaneously in the animal that imparts the disease, and it is mostly confined to the dog and the cat; but that, for its production in the human species, the matter must be received by the rabid animal, and must enter the blood-vessels; so that if some of the saliva should accidentally get on the skin, without penetrating it, there is nothing to be feared. It may be remarked that a degree of the disorder may be produced by a highly irritated dog or cat which is still not irritated into actual madness; and the apprehensions of the bitten would be calculated to establish the simulated malady; but although the symptoms in these cases might for a time resemble real hydrophobia, (and the imagination itself will work up this condition,) yet the termination in the one and the other case would soon prove the difference. With respect to the time which the virus may be latent in the system without coming into actual operation nothing certain has been ascertained. Thus much is certain that weeks and months have elapsed between the infliction of the injury and the production of the disorder.

In regard to the proximate cause of the malady, it has in this case, as well as in tetanus and other violent affections of the nervous frame, been endeavoured to be proved that some spinal, or tracheal, or cerebral inflammation, has been the immediate result of the poison's influence, and that the external showings of the distemper have depended upon these local inflammations; but the extreme irregularity in morbid appearances after death are seemingly inconsistent with these theories; and it is perhaps more correct to infer that the primary action of the virus is rather upon the nervous organisation, and that these congested and inflammatory conditions are consequences rather than causes of the general perturbation.

Prognosis.—In the highest degree unfavorable: indeed it is doubtful whether any real case of hydrophobia has ever yielded to any medicinal trials. We have conversed with a medical prac-

titioner of respectability in Hertfordshire, who affirms that he once saw the actual symptoms of hydrophobia arrested by the employment of a ouack medicine which has gained celebrity in that part of the country, and which is supposed to be constituted of very large doses of meadow saffron; but even in the face of such evidence we cannot help being sceptical when we hear all around us of the constant failure of all trials.

Treatment.—Of this then of course nothing need be said, excepting that excision of the bitten part ought to be had recourse to as soon as possible, and during the absence of a person who should be equal to this incision, a tight ligature ought immediately to be made round the limb between the bitten part and the brain; for it seems that this may for a time be preventive of the reception of the poison into the system.

On the subject of incision and prevention, we may be permitted to extract the following remarks from Dr. Thomas.

As in rabies, when once manifested in the system, the power of medicine and all human skill have failed in most instances, our views should be early directed to prevent the accession of the disease; and for this purpose the most effectual is excision of the wounded part, with free ablutions and scarifications. Immediately, therefore, on the infliction of the bite, or as soon afterwards as possible, ablution with water and soap should be had recourse to, and be continued until professional aid is procured. On the arrival of the surgeon, a free and complete excision of the bitten part is to be made, taking care to carry the knife to a sufficient depth, so as to ensure its complete removal. The excised part, being removed, ought carefully to be examined to see if there is any place in the piece through which the dog's teeth appear to have passed; and, in case there is, the excision ought to be carried still deeper than before. Should the knife, on a close examination, appear to have entered the wound made by the dog's teeth, it may be adviseable to recommence the operation with a clean knife, lest the other should be contaminated by its having entered the wounded parts, and by which the sound ones might become inoculated with the canine virus.

The sooner that the wounded part is extirpated after the accident the better; but it will be right to do it even at the distance of several days, rather than that the person should be debarred of the chance which excision affords, as there is great reason to presume that the canine poison does not enter the system so quickly as a variety of others are perceived to do. This conclusion we are somewhat authorised to draw, as in several well-attested cases, many weeks, nay months, have intervened between the accident of being bitten, and the appearance of the disease. If the bite be of long standing, and the wound consequently cicatrised, and there be a certainty that the animal by which it was inflicted was really rabid, it should immediately be laid open, cauterised, and caused to suppurate.

Dr. Darwin observes, that if the patient is bitten in a part which could be totally cut away, as a finger, even after the hydrophobia appears, it is probable it might cure it, as he suspects the cause still remains in the wounded tendon, and not in a diffused infection tainting the blood. Hence there are generally uneasy sensations in the old cicatrix before the hydrophobic symptoms commence.

Even in cases where assistance has not been requested until the consequent disease has already appeared, I am of opinion that the wounded parts should be excised: for if the excision of the part, in which the virus of small-pox, syphilis, or any similar disease is deposited, after the local action has evidently commenced, prevents absorption, and consequently the complete formation of the general disease; what reason is there for supposing that the same effect would not result from this operation, at the same period, in the case of the bite of a rabid animal; if the poison enters the system by the absorbents.

After excision, ablution is again to be performed with a solution of volatile alkali in water, and, when the flow of blood begins to cease, suction with the cupping-glass may be resorted to. The alternate employment of ablution and the exhausted receiver may be continued for some hours. Having proceeded thus far, caustic, such as the argenti nitras, or potassa fusa, may be applied to the wound, so as to produce a slough in the first instance, and afterwards a purulent discharge for some weeks. By this mode of treatment many persons have been known to escape the disease; while others who have been bitten by the same animal, and who neglected these means, have become affected.

It sometimes happens that the wounded or bitten part is so situated as not to admit of excision, or from the timidity of the patient he cannot be persuaded to submit to the operation. Under this dilemma we must be content to have recourse to a careful and persevering ablution, and afterwards to scarification and cupping, bathing the parts with warm water to promote a free flow of blood, in order to assist in washing away any remaining particle of the poison. With respect to the fluid to be employed at first in the ablution, a weak solution of volatile alkali, in the proportion of one part of the alkali to four of water, may be as proper as any we can use. With this solution, which is fully capable of dissolving the saliva, the wounded part should be freely washed, and injections with a syringe forcibly be made into the wound. After this, water may be substituted to assist in washing away any remaining particles of the canine poison. Having washed the wound for a considerable time, it may be touched with caustic, the argenti nitras, or the potassa fusa. Ligatures above and below the wounded part have been recommended during the ablutions by Dr. Percival, when they can be put on.

The bitten part must be destroyed to the bottom, by repeated applications of the caustic. To assuage the inflammation caused thereby, the wound is to be dressed for some time with poultices, and afterwards with acrid dressings and hot digestives, to remove the eschar, create a discharge, and drain the injured parts. Where there has been any delay after the accident, the wound should thus be kept open for two or three weeks, or even longer.

From some experiments made by Dr. Linke of Jena, with the saliva taken from a mad dog after it was dead, and that had bitten other animals with a fatal effect, the external application of a strong solution of white arsenic in water, to wounds besmeared with the poison, appears to have been attended with the happy effect of destroying the virus, and of preventing the disease from taking place. The remedy seems therefore worthy of further trials in wounds made by rabid animals.

Under the head of animal poisons it is mentioned that the external application, as well as the internal exhibition of the liquor ammoniæ, was found on many trials entirely to do away the injurious consequences arising from the bite of the cobra de capello, a snake of the most venomous kind, and productive of symptoms pretty similar to those arising from a rabid animal. The same remedy would, therefore, seem worthy of a trial in cases of hydrophobia; but as there would be great difficulty in administering caustic volatile alkali in a state necessarily diluted with some mild bland liquor, where the increased sensibility of the fauces and the dread of liquids are so strongly felt, we might convey it into the stomach in the manner practised by Mr. John Hunter, and hereinafter mentioned, or we might mix the volatile alkali with crumbs of bread, and form the mass into pills, or a bolus. (Stomach pump.)

In addition to these modes of prevention, it has strongly been recommended to commence, very speedily, a course of mercurial unction, which is to be continued regularly, and to be applied in a considerable quantity at once, so as to occasion some degree of salivation; to expedite which the submuriate of mercury may be given internally night and morning, and warm-bathing be used occasionally. Mercurial fumigations may also assist.

With the design of exciting a rapid salivation, in hydrophobia, Dr. Darwin has suggested that one grain and a half of the hydrargyri oxymurias dissolved in half an ounce of rectified spirit may be given frequently to the patient with a prospect of advantage. From a paper by Mr. Addington of West Bromwich, inserted in the Contributions of Medical Knowledge published by Dr. Beddoes, it appears that a similar mode is adopted by him for the cure of gonorrhœa virulenta, and that he has cured hundreds in a very short time in this manner, without the least disagreeable consequence. He directs us to proceed as follows: three grains of hydrargyri oxymurias are to be dissolved in one ounce of rectified spirit. Half of this mixture is to be taken undiluted at going to bed; it produces a copious salivation for an hour and a half, or longer, during which the patient spits about a quart. Some aperient salts are to be taken on the second day after this operation, and on the evening of that day he is to repeat the draught, and the salts on the day but one following.

Dr. Thomas Reid, in a pamphlet which bears the title of Observations on the Application of warm and cold Sea-bathing, recites a case which strongly attests the preventive effects of mercury. He makes mention that a man, a woman, and several dogs, were bitten by a supposed mad dog, who was soon after destroyed. A fortnight after the accident, he saw them; the woman was slightly wounded in the little finger, a black scab remained on the puncture: she had great pain in the arm, shooting up to her head, particularly in the night, with disturbed and frightful dreams, and great depression of spirits. The man had been bitten in the hand also, but had not so much pain. He directed mercury for them in the manner published by Dr. James. In a few days the symptoms abated; and, as the woman's mouth was sore, she desisted from using it. The pain, however, returned very soon, greatly augmented and affected her head; she resumed the medicine, and every symptom vanished; they both remained perfectly well. Had any return of the disease taken place, he is certain he should have been informed of it.

Dr. Reid further mentions, that the same medicine was given to dogs; but by some accident one of them was forgotten, and took none; he became raving mad the thirtieth day, and in that state he had him shot; all the other dogs remained well, except a small lap-dog, which died of the salivation. Neither the man nor woman supposed the dog to have been mad, until they began to take the medicine; the mind had therefore no influence in producing the symptoms that ensued.

These facts seem well authenticated, and strongly attest the good effects of mercury, when used at an early period. During the actual presence of the disease, its inutility has been proved in numberless instances. Dr. Mosely has, indeed, recorded a case of recent hydrophobia, and timely discovered, which was successfully treated by exciting a rapid and plentiful salivation by means of an ounce of strong mercurial ointment rubbed into different parts of the body at four frictions within forty-eight hours.

Dr. Richard Pearson, of Birmingham, in his Treatise on Hydrophobia, offers it as his opinion, that if the disease has ever been cured by mercury, it has been in consequence of a counter-impression communicated to the whole system, and not in consequence of the salivation; for a salivation is a constant symptom of the disease, so that if it were curable by a flow of spittle, it would cure itself. This seems, however, a vague mode of reasoning.

410. *Insanity.*—We now proceed to treat of that order of maladies which Dr. Cullen considers mental or vesanic, in contradistinction to those which are merely nervous. The qualification with which this peculiarity of disorder is to be admitted will be commented on as we proceed; meantime we announce our intention of treating madness in a manner somewhat different from that which we have adopted in reference to other affections; and we shall conclude the genera amentia, melancholia, and mania, under one division. Oneriodynia will afterwards fall to be noticed separately.

In endeavouring to define insanity, we meet with difficulties which are peculiar to itself, since there is a want of an entire coincidence in sentiment respecting the precise standard of mental health; and, until such standard be agreed on by universal consent, the deviations from it cannot of course be easily pointed out with that

decision and accuracy which correct definitions demand.

By one writer, 'an erroneous judgment and irrational conduct,' have been described as the essentials of insanity. In this definition, however, it is immediately seen that a fixed point of rationality and rectitude is assumed, which we have just stated does not exist in the common consent of mankind.

The same objection lies against that announcement of mental alienation which makes it consist in the want of correspondence between the estimate and real value of things.' 'If every one,' says Dr. Darwin, 'who possesses mistaken ideas or puts false estimates on things, were liable to confinement, I know not who of my readers might not tremble at the sight of a madhouse.' Even the objector, however, to the above definition admits too much. As there is no standard of rationality in the sense the above definition assumes; so, in strictness of language, there is no admissible difference between false and true with respect to our 'estimate of the value of things.'

The miser locked in his solitary closet, and lost in the contemplation of his golden stores, is regarded as insane by the youthful voluptuary, who has no other notion of the value either of specie or paper but as they furnish him with the means of sensual gratification; with the latter, however, the former is equally in his senses, provided he act, as indeed he necessarily does, in conformity with his inclinations, or, in the words of the definition upon which we are commenting, 'his estimate of the value of things.'

Neither will Darwin's own definition bear the test of rigid scrutiny. 'Madness,' says this author, 'is an excess of action in the sensorial power of volition.' In this account we must necessarily include the late emperor of France. Where is the man whose volitions were more in excess, during the zenith of his power and splendor, than Napoleon Buonaparte? Yet, however desirable to Englishmen it might always have appeared that this extraordinary individual should as soon as possible be put out of harm's way, we surely never could have desired his confinement on the score of his being a maniac.

Again, it is not the volition, but the influences operating upon the mind to engender the volition, which form the criterion of the healthy or deranged condition of the understanding. 'Madness,' says a modern author, with equal force and propriety, 'is not a disease of action, but a disease of motives to action.'

In that very entertaining section of the Zoonomia which is devoted to the subject of mental hallucination, we find it stated that a gentleman ordered his servants to be all stripped before him in order to examine them. In consequence of this procedure he was confined as a maniac; and, after much persuasion, he was prevailed upon to tell the medical attendant that he had got the itch, and that he had determined to examine all his domestics separately and minutely in order to ascertain from which of them he had contracted it. At the time, however, of this transaction, there was not a spot to be seen on the individual's hands, or on other parts.

Now in this case the hallucination consisted not in the volition to satisfy the particular conceit, but in the conceit itself; it was a derangement rather of sensation than volition, or, more strictly speaking, the complaint was constituted by strength of passion, rendering the ideas of conception more prominent than those of perception; and, by consequence, producing a volition which, although wild and incongruous in reference to former feelings and associations, was in conformity and consistency with such as at the time prevailed. In like manner, if conceiving, or in other words believing, myself to be too bulky to pass through a door-way, like the late Dr. Watts, I will, or order, its dimensions to be increased, neither are my volitions inordinate nor my reasonings incorrect; nor are they so, if, like the mad philosopher in Rasselas, actuated by the consciousness of possessing power over the elements, I will and command the thunder to roll, the lightning to flash, and the rain to fall. 'He does not,' says a modern author, 'reason falsely, but more properly furiously deceives himself; who, fancying himself to be Jove, hurls Jove's thunderbolts,—Non malê ratiocinatur, sed potius furens decipitur, qui Jovem se credens Jovis fulmina jaceret.

Dr. Mead makes madness to consist in 'increased strength of imagination.' But by this enunciation the poet, or the man of inventive genius, is classed with the insane, and Shakspeare and Milton are made to stand highest in the list of maniacs. 'The strength or increase of any power of the mind,' says Haslam, 'cannot constitute a disease of it. Strength of memory has never been suspected to produce derangement of intellect, neither is it conceived that great vigor of judgment can operate in any such manner. On the contrary, it will readily be granted, that imbecility of memory must create confusion, by obstructing the action of other powers of the mind; and that, if the judgment be impaired, a man must necessarily speak and generally act in a very incorrect and ridiculous manner.'

Dr. Arnold, who has written very largely on the topic now under discussion, divides insanity into ideal and notional: the first he defines that state of mind in which a person imagines he sees, hears, or otherwise converses with, or perceives persons or things, which either have no external existence to his senses at the time, or have no such external existence as they are then conceived to have, or, if he perceives external objects as they really exist, has yet absurd and erroneous ideas of his own form, and other sensible qualities.

Notional insanity, he says, is that state of mind in which a person, hears, sees, or otherwise perceives, external objects as they really exist, as objects of sense, yet conceives such notions of the powers, properties, designs, state, destination, importance, manner of existence, and the like, of things and persons, of himself and others, as appear obviously and grossly erroneous or unreasonable to the common sense of the sober and judicious part of mankind.

With respect to the first of these distinctive delineations of the constituents of insanity, it may be observed that the definer, although neare

correctness, perhaps, than some others, seems to suppose that false perception implies an absolute and abstract difference in the object perceived; and as to the second division it is obviously in some sort objectionable, upon the same principle upon which we have ventured to object to some other definitions, namely, that it assumes a test of notional rectitude, which neither does nor can exist. How absurd do the notions which the miser entertains of the nature and value of money, appear to the majority of mankind! and yet we cannot with any propriety attach the imputation of madness to either the notions themselves or the resulting conduct. Indeed the ad absurdum extreme of Dr. Arnold's position, respecting difference of opinion as constituting insanity, would make the much talked of remark of the Bedlamite to be as sensible an assumption, as ever was put into language; who, upon being questioned as to the why and wherefore of his confinement, replied, 'The reason, Sir, is this; I conceive the whole world to be mad—the world, returning the compliment, supposes me to be in the same predicament, and, the many being more powerful than one, here they have locked me up.'

In what then, to return to our query respecting definition, in what does insanity consist? In our remarks on one of Dr. Darwin's examples of mental hallucination we have stated that strength of sensation or passion, rendering the ideas of conception more forcible than those of perception, gives birth to incongruity of association, and consequent incoherence of gesture, speech, or action. Of this disordered association, then, is insanity formed; by incoherence of conduct is it displayed; and by the intensity of the prevailing sentiment or passion has it been produced.

We would therefore define madness, intensity of idea causing imagination to be converted into actual belief; and it will now be our endeavour to illustrate and defend this position, as well as to point out what we conceive to be the practical importance of thus considering the line of demarcation between mental health and disease, to be mainly, if not absolutely and entirely, made up of difference of belief or persuasion.

Suppose an individual to be present at a theatrical representation. Let his imagination be warmed, and his passions excited by the scenes which are presented to his senses. Let him follow with ardor the fortunes, and engage with interest in the events, connected with the principal personage of the drama. Still he has no belief in the actual existence of the fictitious character—or at least his belief, if it does exist, is merely momentary. Otherwise he would not applaud the faithfulness of representation in the actor, but the passion which the actor feigns. Again, our individual admires the beauty and fidelity to nature of the scenery, but he does not therefore suppose himself transported to the actual place which the scene represents. In other words his heightened conception or imagination still stops short of the pitch of overpowering his perceptions. Suppose, however, that the vividness of the representation should hurry the feelings and exalt the fancy to such a degree of intensity, as to break into, and in a manner overwhelm, the usual order of perceptive ideas; the spectator would now be carried above the reach of reason or of truth, he would actually, as a modern writer expresses it, see Alexander and Cæsar before him in the persons of his old familiars, a room illuminated with candles now comes to him to be the plains of Pharsalia, or he believes that his walk to the theatre has been a voyage to Egypt, and that he lives in the days of Antony and Cleopatra.

Allowing then the correctness of this assumption, respecting the essentials of insanity, we might say in other words that it is delusion more transient, or more permanent, more partial, or more general; the imagination having overwhelmed the perceptions, and the understanding having fallen prostrate under the violence of the conflict.

Vividness of imagination, then, although in itself a condition of mind very far different from madness, may come at length to be productive of positive insanity, and hence we find that the principal sources of mental derangement are those influences which, so to say, seize upon and hurry away the conception, leaving at a distance, and in a debilitated, confused state, the remaining faculties and functions of the mind.

But it may be said that there are many instances of mad actions, which seem to be the result rather of ungovernable impulse, than of false conception. There is a sort of insanity, it will be urged, in which the subject of it commits actions, and expresses feelings, which he at the time knows to be immoral and irrational. Now here appears to be the stand which it behoves both the moralist and the metaphysician to make against the admission of that laxity of sentiment which goes to the destruction, not only of the land-marks of distinction between sanity and madness, but of every principle of right and wrong. 'I am aware that such an action is not consistent with the dictates of virtue, but still I am goaded on to its commission, by an absolute necessity or irresistible impulse,' is a plea that might be instituted for every sin against conscience or better feeling, and might stand as a legitimate apology for the most flagitious crimes whether public or private, selfish or social, political or moral. And, indeed, something like this defence has been set up in favor of actions which in one view of the case are acts of criminality, in another deeds of madness. Dr. Darwin gives us the following recital as an instance of insanity. Mr. ——— a gentleman of polished manners, who in a few months after destroyed himself, said to me one day, 'a ride out in the morning, and a warm parlour, and a pack of cards in the afternoon, are all that life affords,' and, as he was weary even of these enjoyments, he had determined to put an end to his existence. He was persuaded, says Dr. D., to have an issue on the top of the head, as he complained of a dull head-ache, which, being unskilfully managed, destroyed the pericranium to the size of an inch in diameter; during the time this took in healing, he was indignant about it and endured life, but soon afterwards shot himself. Now if we admit such cases as these to be cases of madness, at what point shall we cease to deplore, and

begin to condemn. Is not the distinction between virtue and vice of the most unfounded and visionary nature? and is not the implication and punishment of guilt in all instances not only cruel but absurd? Inferences like these have indeed been adduced in some recent publications of a very acute and logical cast, and they are conclusions which cannot fail of being drawn from those premises that predicate organisation as the ultimatum of every thing intellectual and moral.

But still it will be urged that many cases do often occur, and those of the most melancholy character, which both feeling and philosophy would command us to put down to the score of actual and positive irresistibility, rather than refer to a vicious and voluntary compliance with the dictates of passion. We hear often, it may be said, of most affectionate parents conceiving and actually perpetrating the murder of their offspring. The hand of the loving husband has been known to be lifted up against the wife of his bosom. The wife has sought to extinguish the life of her husband. The man marked for morality, and even distinguished for religious sentiment, sometimes plunges the dagger of destruction into his own breast. The individual noted for delicacy of conversation and correctness of conduct will, under some circumstances of disease, even revel in the dreadful luxury of loose and licentious language and demeanor.

It must indeed be allowed, that the distinction between criminality and madness in these cases of impulse, apparently beyond control, is one of especial difficulty and nicety, and requires much and very minute attention to every peculiarity and bearing of the individual case; it must, moreover, be admitted, that as it relates to the individual a correct opinion is sometimes almost impossible; and feeling of course would always point to the merciful side in dubious instances; especially as so little is in our power with respect to an accurate estimate of other interior states from external indications visible to us. In all the examples of the kind of insanity now under notice, the subject of it, during the actual commission of the act, upon the degree of criminality of which we may be called upon to decide, has verily conceived or believed himself, for the time being, to be acting according to the necessity of things; it being in his lucid intervals only that the maniac feels a consciousness of the deed that he had contemplated or executed. While the hallucination is actually upon him he believes that he is obeying imposed laws, or acting under the influence of superior mandates. But let it be recollected that nothing of this kind can be brought forward in favor of mere gusts of passion, or even of many cases of self-destruction, which last, as in the instance just cited from Darwin, are sometimes inflicted with a deliberate calculation, and dreadful venture, as to present circumstances and future states; and have, therefore, no more legitimate title to the excuse of insanity, than has the act of the gamester, who, with a dread resolve growing out of incipient despair, offers his last stake, and thus voluntarily reduces himself to wretchedness and beggary.

We repeat, however, that it is actually necessary to take into account that changes take place in the sentient part of our organisation which often are only visible in their effects, while the changes themselves are as truly physical as had they been fully demonstrated; and while we think it right, both upon moral and physical grounds, to check the extension of insanity into an unjustifiable lax degree, we should be erring still more on the other side in looking upon self-destruction indiscriminately as an immoral act. On the very day that we are penning these remarks, we have seen in the daily papers a melancholy account of suicide in one of our first poets and a most virtuous man—we speak from personal knowledge—and who does not recollect with sympathy and melancholy regard, the names of Romilly, Whitbread, and Castlereagh?

In these cases, we say, there is evidence of bodily disorganisation, or some effect beyond the mere motive of avoidable passion; and, we repeat, that in all cases of mental aberration, whether indicated by act or feeling, some change in the corporeal structure is properly presumable.

The bodily disorganisation, that we presume thus to be invariably connected with mental disease, may be primary or secondary; that is, the condition of the corporeal frame may be either such as that the common excitants shall be sufficient to occasion the derangement, or the exciting power or powers may be applied with such intensity as more positively to operate the change in question: although in this last case it may be supposed that there is, in the majority of instances, at least a predisposition thus to be affected by extraordinary excitations.

There is one fact which would go to prove, if proofs were wanting, the bodily affection in mental disease which we now contend for: and that is the remarkable and almost instantaneous mutation which is sometimes made of more obviously corporeal, for more strictly mental disorder. Take the following affecting recital from the works of Dr. Mead, in illustration of this particular:—'A young lady, about eighteen years of age, was attacked with a spitting of blood and cough, which, although active treatment was pursued, was soon succeeded by hectic fever, night perspirations, and every symptom indicative of a rapid, and menacing a confirmed, consumption. Death indeed stared her frightfully in the face. The anticipation of the event struck the patient with horror in respect of futurity, and the consequence was a state of furious mania. In the mean time her bodily condition began to amend, the fever and sweats subsided, the spitting was arrested, and every thing promised a complete recovery. From a condition of high mental agitation she now fell into melancholy; and this was in the course of three months succeeded by calmness and composure of mind; but, alas! with the return of her reason, her bodily complaints likewise returned, and this fine young creature very shortly died of actual consumption of the lungs.'

Still more remarkable however is the fact, that disorders of the body will sometimes have

effect of locking up as it were, and concealing from view the mental energies for a long series of years; and when it is asked respecting a paralysed individual where is the immortal mind which was wont to animate the features, and guide the conduct of this man, now reduced to a state of mere animal vitality, we might appeal to instances, and they are not a few, in which, just prior to the period of the total extinction of the living principle, the soul seems to come out from its hiding place, and to cast a parting glance at the surrounding scene. Who has not dwelt with agonising delight upon the transcendantly beautiful representation by Mrs. Opie, in her inimitable work entitled the Father and Daughter, where she makes the return of reason in the distracted parent to be the signal that all is about to close with him, as far as this world is concerned? and the delineation is no less true to nature than it is impressive and affecting. Not long since we heard from a respectable physician, of the Society of Friends, of an intelligent and most respected individual of that society, who had been deprived of his faculties for years by a stroke of palsy, nay, to use our friend's words, 'who had been for this long time in a state of drivelling idiotcy, but who, for some days previous to his death, was restored to the full possession of his rational powers; he summoned his astonished family around him, delivered to each of them his parting advice and benediction, and then calmly resigned himself to a peaceful death.'

In a pamphlet published some time since, by Mr. Tuke, we meet with the recital of a most singular case, bearing upon the point of that vicarious and alternate visitation of disease of the body and mind, to which we have just alluded.

'A young woman,' says Mr. T. (we extract from the Edinburgh Review), 'who was employed as a domestic servant by the father of the relater, when he was a boy, became insane, and at length sunk into a state of perfect idiotcy. In this condition she remained for many years, when she was attacked by typhus fever; and my friend, having then practised medicine for some time, attended her. He was surprised to observe, as the fever advanced, a development of the mental powers. During that period of the fever, when others were delirious, this patient was entirely rational. She recognised in the face of her medical attendant the son of her old master, whom she had known so many years before; and she related many circumstances respecting his family, and others which had happened to herself in her earlier days. But alas! it was only the gleam of reason; as the fever abated, clouds again enveloped her mind. She sunk into her former deplorable state, and remained in it till her death, which happened a few years afterwards.'

But it has been above remarked, that the accompanying bodily affection in cases of mental derangement may be secondary; that is, it may be induced by the violent action of the cause which may have induced the insanity itself. In this last case, we have moreover said that, although the excitation is from without, it is fair to presume upon some interior condition of the physical frame, different from its ordinary tone and tenor. Dr. Ferrier, it is well known, has aimed at tracing the belief in ghosts to accidental impressions, made upon the mind of the believer, under certain states of the body, which have thus proved of sufficient force to cause the belief and supposed sight of spectral images; but which, happening to impinge as it were upon this same body, under different circumstances, would have passed unheeded, or, at furthest, would have been regarded merely as the freaks and flittings of fancy. Whether this ingenious speculatist has substantiated his data to the extent contended for, we may leave to others to determine. In the mean time we will relate a case, which, although of foreign occurrence, stands already recorded in two accredited publications of our own country; and for the authenticity indeed of which, the respectability of the original narrator may be taken as a sufficient pledge.

'A student of Jena, about sixteen years of age, having a weak and irritable nervous frame, but in other respects healthy, left his apartment during twilight, and suddenly returned with a pale dismal countenance, assuring his companion that he was doomed to die in thirty-six hours, or at nine o'clock in the morning of the second day. This sudden change of a cheerful young mind naturally alarmed his friend; but no explanation was given of its cause. Every attempt at ridiculing this whimsical notion was fruitless; and he persisted in asserting that his death was certain and inevitable. A numerous circle of his fellow students soon assembled, with a view to dispel these gloomy ideas, and to convince him of his folly by arguments, satire, and mirth. He remained however unshaken in his strange conviction, being apparently inanimate in their company, and expressing his indignation at the frolics and witticisms applied to his peculiar situation. Nevertheless, it was conjectured that a calm repose during the night would produce a more favorable change in his fancy; but sleep was banished, and the approaching dissolution engrossed his attention during the nocturnal hours. Early next morning he sent for professor Hufeland, who found him engaged in making arrangements for his burial; taking an affectionate leave of his friends, and on the point of concluding a letter to his father, in which he announced the fatal catastrophe that was speedily to happen. After examining his condition of mind and body, the professor could discover no remarkable deviation from his usual state of health, except a small contracted pulse, a pale countenance, dull or drowsy eyes, and cold extremities; these symptoms, however, sufficiently indicated a general spasmodic action of the nervous system, which also exerted its influence over the mental faculties. The most serious reasoning on the subject, and all the philosophical and medical eloquence of Dr. Hufeland, had not the desired effect; and though the student admitted there might not be any ostensible cause of death discoverable, yet this very circumstance was peculiar to his case; and such was his inexorable destiny that he must die next morning, without any visible morbid symptoms,

In this dilemma, Dr. Hufeland proposed to treat him as a patient. Politeness induced the latter to accept of such offer, but he assured the physician that medicines would not operate. As no time was to be lost, there being only twenty-four hours left for his life, Dr. Hufeland deemed proper to direct such remedies as prove powerful excitants, in order to rouse the vital energy of his patient, and to relieve him from his captivated fancy. Hence he prescribed strong emetics and other medicines, and ordered blisters to be applied to both calves of his legs. Quietly submitting to the doctor's treatment, he observed that his body being already half a corpse all means of recovering it would be in vain. Indeed, Dr. Hufeland, on repeating his visit in the evening, was not a little surprised to learn that the emetic had but very little operated, and that the blisters had not even reddened the skin. The case became more serious, and the supposed victim of death began to triumph over the incredulity of the professor and his friends. Thus circumstanced, Dr. Hufeland perceived how deeply and destructively that mental spasm must have operated on the body, to produce a degree of insensibility, from which the worst consequences might be apprehended. All enquiries into the origin of this singular belief had hitherto been unsuccessful. Now only, he disclosed the secret to one of his intimate friends, namely, that on the preceding evening he had met with a white figure in the passage, which nodded to him, and in the same moment he heard a voice exclaiming, 'The day after to-morrow, at nine o'clock in the morning, thou shalt die.' He continued to settle his domestic affairs; made his will; minutely appointed his funeral; and even desired his friends to send for a clergyman, which request, however, was counteracted. Night appeared—and he began to compute the hours he had to live, till the ominous next morning. His anxiety evidently increased with the striking of every clock within hearing. Dr. Hufeland was not without apprehension, when he recollected instances in which mere imagination had produced melancholy effects; but, as every thing depended upon procrastinating or retarding that hour in which the event was predicted, and on appeasing the tempest of a perturbed imagination till reason had again obtained the ascendancy, he resolved upon the following expedient: having a complaisant patient, who refused not to take the remedies prescribed for him (because he seemed conscious of the superior agency of his mind over that of the body) Dr. Hufeland had recourse to laudanum combined with the extract of henbane; twenty drops of the former and two grains of the latter were given to the youth, with such effect, that he fell into a profound sleep, from which he did not awake till eleven o'clock on the next morning. Thus the prognosticated fatal hour elapsed; and his friends waiting to welcome the bashful patient, who had agreeably disappointed them, turned the whole affair into ridicule. The first question, however, after recovering from his artificial sleep, was 'What is the hour of the morning?' On being informed that his presages had not been verified by experience, he assured the company that all these transactions appeared to him as a dream. After that time he long enjoyed a good state of health, and was completely cured of a morbid imagination.'

This very curious example of the influence of the imagination upon both the mental and bodily condition of being, may be considered as instructively interesting in several points of view. In the first place the possibility is established of a bodily affection originating in a mental cause; and it forms, therefore, an insuperable obstacle to the admission of that postulatum which demands that every thing which we are accustomed to consider and to call mind be placed to the account of organic operation as its source. Without the addition or subtraction of a particle of matter to the frame, actual disease, we see, may both be induced and suspended; and, if the presumed predisposition to fall into such disease be admitted as evidence of organisation having to do with the effect, this kind of argument ceases to be applicable to the point of the disorder's cessation, which it will have been remarked took place with the rapidity of a charm, when the prevailing fancy upon which it depended was proved to the patient to have no foundation in fact.

In the second place, the example just adduced may serve to show the impropriety of opposing with the weapons of reason or ridicule those fantasies, and feelings, and convictions, which however ungrounded in the abstract, and in fact, have nevertheless a certain sort of truth in them as it refers to the individual influenced. Prove, if you can, and as professor Hufeland by a dexterous ruse in the present instance did, that maniacal illusions are illusions; but never attempt to convince a madman, or even a nervous invalid, against the evidence of his own senses and feelings.

Lastly, it may be observed that the fulfilment of alleged predictions in respect to events supposed to be communicated in a supernatural way, by no means proves the verity of these pretensions, since the conceptions themselves may come to operate the circumstance predicted, and thus a mere physical incident would be apt, by the generality of judges respecting events of this nature, to be set down as a visitation from the world of shadows. The much-talked of death of the late lord Lyttleton, for example, is sufficiently accounted for by mental and physical causes, without looking for its explanation to an especial interference of divine providence. The Horatian maxim in respect of poetry, not to introduce superior agency unless the occasion obviously demands it, is especially applicable when philosophy is concerned; and, while we reject the sceptical tenets of necessity as conducting to error in principle and mischief in effect, let us as carefully close our ears against the calls of superstitious credulity to enlist ourselves under her blood-stained banners.

We may be permitted to add a few words more on the sources and preventives of nervous affections: of nervous affections, we say; for, inconsistent as at first sight it may seem with the limitations proposed respecting the essentials of insanity, we would express it as our conviction

that there is a certain kind of truth in the strongly expressed axiom of a modern author, that 'every nervous disease is a degree of insanity;' in other words, when fancies are substituted for realities, absolute sanity can never be predicated: there is a certain degree of delusion present, or a belief in the existence of things that have no other entity than in the mind of the recipient and sufferer.

Let us again be indulged while briefly illustrating our meaning by examples. Two individuals shall be on the bed of sickness, both of whom shall complain of an equal degree, although of a different kind of disorder, and the complaint shall virtually for the time be of the same measure in either; but in this consists the difference that the illness of the one is positive—of the other, so to say, negative; or, in other words, the loss of power will be only susceptible of very gradual restoration by the due employment of physical agents in the first; while the latter, though apparently equally feeble and helpless, only requires the proper kind of stimulus to be applied, and the complaint will immediately disappear as if charmed away by the power of magic. After what has been stated, in a preceding part of the present paper, it will not surely be suspected that we mean to insinuate there is not actually a bodily disorder in the one case as well as in the other; all that we wish to infer is the difference of the two states supposed; the one being frequently vincible by mere mental excitants, the other necessarily under the control only of physical agents.

Dr. Reid, in his treatise on Nervous Ailments, has given the history of a very instructive case, under the title of Real Evils a Remedy for those of the Imagination. This, with a very curious but well-authenticated case from Dr. Mead, we shall in the first place take the liberty of laying before our readers, and then add a few observations on the practical advantages which might be made of such occurrences.

'Some years ago,' says Dr. R., 'I knew a lady who had been for a long time a miserable victim to the vapors, but who was completely cured of this complaint by the supervening of another, which was more immediately alarming, and which precluded indeed the possibility of much longer life. No sooner was her new disease ascertained to be an aneurism of the aorta, and the necessary result of that complaint was explained to her, than all her nervous feelings vanished; and she even bore the announcement of her inevitable fate with a calmness which is seldom exhibited under such trying circumstances. The near prospect of death, instead of overpowering, seemed to brace anew the relaxed energies of her frame; and, what is worthy of remark, so far from being during her subsequent days, selfishly absorbed by her real, as she had before been by her imaginary ailments, she interested herself almost continually and exclusively about the happiness of others; and in proportion as she became more amiable she became less wretched.'

The case of Dr. Mead is as follows:—'An academic became so deeply imbued with imaginary fears respecting his health, that, after having taken to his bed for some time, he at length insisted that he was actually dying, and ordered the passing bell of the church which was contiguous to his house, to be tolled for his departure. It was in a catholic country. He had been himself accustomed when a young man, for the sake of exercise, to ring this same bell, and by this practice having acquired a connoisseurship in the art of tolling, he found himself displeased with the manner in which the present performer executed his task; and, thus irritated with the man's bungling, he sprang out of bed, and with his own hands showed him the manner in which he would have it done. He then returned to his bed bathed in perspiration, and was ever afterwards free from complaint. Vitam autem reddidit iste labor et convaluit.'

Now, although it is not very often that the actual distinction between nervous and other complaints shows itself in so marked a manner as in the above recitals, yet common and every day occurrences are degrees of the same evidence; and these more conspicuous instances of actual capacity, combined with imaginary inability, might be made to serve, if properly applied, a very useful purpose.

A combination, it will be allowed, of mental and physical impulses, is for the most part operative in the production of every grade of mental and nervous derangement; and thus we have it sufficiently explained why these derangements become more numerous in proportion as we recede from simple and rustic, and advance to social and refined habits. Every augmentation of our enjoyment supposes, by a law of nature, an increased susceptibility to suffering; and when the surface of impression is thus constantly, as it were, beaten out into increased expansion, by the multiplication and successively new conjunction of existing agents, it is not surprising that life thus rendered more artificial and more complicated, becomes in the same ratio more obnoxious to disgusts and derangements. It is a remarkable fact, that in savage life even intense passions, such as love and religious fervor, do not operate as they do with us, a deterioration of the understanding beyond mere fallacy of judgment, and consequently irrational conduct in immediate reference to the subject of the prevailing sentiment. And why is this? Palpably because the movements of the mental and bodily frames of the savage are, so to say, regulated by less complicated machinery, and therefore less likely to be irregularly excited. 'In proportion,' says an eloquent writer, 'as man emerges from his primeval state do the furies advance upon him, and would seem to scourge him back into the paths of nature and simplicity.'

Having thus briefly discussed the question respecting the essentials and sources of insanity, we now proceed to treat the subject somewhat more medicinally, and shall consider the history, prognosis, and treatment of madness, upon the plan which we have generally pursued in the present article.

Symptoms.—'The coming on of madness is marked,' says Haslam, 'by restlessness. Insane patients first become uneasy and incapable of confining their attention; they neglect their accustomed employment; they get but little sleep

they are loquacious and positive on any subject that may be started; soon after they are divested of all restraint in their declaration of their opinion of those with whom they are acquainted; their friendships are expressed with fervency and extravagance; their enmities with intolerance and disgust. They now become impatient of contradiction, and scorn reproof. For supposed injuries they are inclined to quarrel and fight with all about them. They have all the appearance of persons inebriated, and people unacquainted with the symptoms of approaching mania, generally suppose them to be in a state of intoxication. At length suspicion creeps into the mind, they are aware of plots which had never been contrived, and detect motives which were never entertained. All this may exist without the perceptions and associations being sufficiently disturbed to constitute actual madness; at last, however, the succession of ideas becomes too rapid to be examined; the mind becomes crowded with thoughts, and indiscriminately jumbles them together: insanity is established. Patients under the influence of the depressing passions will exhibit a different train of symptoms. The countenance wears an anxious and gloomy aspect; they retire from the company of those with whom they had formerly associated, seclude themselves in obscure places, or lie in bed the greatest part of their time. They next become fearful; and, when irregular combinations of ideas have taken place, conceive a thousand fancies, often recur to some former immoral act which they have committed, or imagine themselves guilty of crimes they never perpetrated; believe that God has abandoned them, and with trembling await his punishment. Frequently they become desperate, and endeavour with their own hands to terminate an existence which appears to be an afflicting and hateful incumbrance.'

Causes.—The causes of insanity are numerous, and the predisposition to run into the insane state is very often indeed connate; although this fact has been attempted to be denied or explained away by several modern authors—as by Brown, Adams, Hill. The hereditary nature of the complaint is not however so absolute and unnecessary as has been, on the contrary, conceived by others; and much family apprehension is often established upon a false foundation in reference to this particular. The exciting causes of madness are physical, mental, and moral; such as inebriety, pride, and the feelings and emotions of whatever nature and kind are calculated in their indulgence to derange the intellect; but the very passions and emotions themselves prove that the business is half accomplished before the specific excitation has been applied. Madness sometimes makes its way into the system through the medium of other more decidedly corporeal complaints; and sometimes, as we have seen, it in a manner dislodges and supersedes these; and it often comes upon a person without any obvious reason either of predisposition or excitement.

The mental causes adduced by Arnold are intense application to business, or study; passions of various kinds; too great activity of imagination, and imbecility. His enumeration of bodily causes is—internal, seated in the brain; external, acting mechanically on the brain. Causes acting on the body generally, and through it upon the brain, either directly, sympathetically, or by translation.

Distinctions.—A great deal has been said of the necessity of distinguishing between melancholia and mania; but these distinctions are scarcely traceable, inasmuch as the fury of maniacal excitement very often passes into the abstraction of melancholy; and in this case, as in other disordered manifestations, we must be careful of not giving rise to the idea of any essential or abstract difference in the essence of disease, merely by inventing terms. Hypochondriacism, or that state which is as it were between sanity and insanity, the completely absorbed state of the melancholic, and the high ravings of the maniac, will be manifested by the same individual. And, as far as bodily and mental disorder must be considered as establishing a distinction, we have already more than once said that the most purely mental affection must in one sense be corporeal, that is, it must be attended with some change in the bodily condition, whether that change be visibly structural, or only cognizable in its effects. When indeed the functions of the stomach are obviously deranged, and such derangement obviously regulates the mental aberrations, the word hypochondriasis may, if you please, apply in the way of distinction from melancholia, which often commences, pursues its course, and becomes confirmed into complete insanity, without appearing to have any thing to do with chylopoietic conditions.

Prognosis.—With regard to prognosis, Dr. Cox, who enjoys ample opportunities for minute observation, tells us that the chances of recovery are against those madmen in whom the disposition can be traced to lunatic ancestry. 'When the causes are manifestly corporeal, a favorable termination may be expected. When the subjects of hallucination vary, and the mind is not obstinately fixed on one topic, hopes may be indulged. The insanity subsequent to parturition is generally curable, if the curative attempts be rational, which is not always the case.' It deserves, however, to be noticed, that the intellect in this case is subject to a second derangement from the same exciting sources, just as abortion has a tendency to recur after it has once happened. 'Palsy, hemiplegia, and diseases of this class supervening, may be reckoned among the unfavorable occurrences.' In these cases the unhappy patient often becomes decidedly, and beyond recovery, fatuitous. 'Patients,' says Haslam, 'who are in a furious state, recover in a larger proportion than those who are depressed and melancholy.' When the furious state is succeeded by depression, and after this shall have continued a short time the violent paroxysm returns, the hope of recovery is very slight. Indeed, whenever these states of the disease frequently change, such alternations may be considered unfavorable.'

Dr. Darwin well observes that, 'when an individual becomes insane who has a small family of children to solicit his attention, the prognosis is very unfavorable, as it shows the maniacal hallucination to be more powerful than those ideas

which usually interest us most.' And Haslam further states, 'that in those instances where insanity has been produced by a train of unavoidable misfortunes, as when a father of a large family, with the most laborious exertions ineffectually struggles to maintain it, the number who recover is very small.' It may be added that, in proportion to the length of time the malady may have lasted, is the hope enfeebled of ultimate recovery. After the disorder has lasted for more than a year, the chances against restoration are great.

The statements of proportionate recoveries from insanity show much discrepancy. The most favorable we have seen is that of Dr. Burrows, who remarks that, if curative attempts are pursued with judgment, eighty-one cases out of 100 may be expected to recover. Of quite recent ones ninety-one in 100; and of old cases thirty-five in 100.

In respect to appearances of the brain, of the liver, and other viscera, when examined after death, there are scarcely any kind of morbid changes which have not at different times been seen; but no certainty of inference has yet been deducible from these appearances, inasmuch as they are by no means regularly conformable with what might, à priori, be expected from analogy, and from the witnessing of other cases. The very same appearances, it has been remarked, have exhibited themselves after the most opposite disorders; and Haslam expressly states, that even the general texture of the brain of maniacs, independently of partial lesions, shows an unnatural firmness, or morbid flaccidity, without any apparent reason why it should be so. Dr. Arnold has been at the pains of collecting from Bonetus, Morgagni, and Haller, their several statements of organic lesion, as of hardened and thickened membranes, turgidity of blood-vessels, water in the ventricles, different conditions of the pineal gland, bloody spots in different parts of the brain itself, purulent matter in its substance or ventricles, enlarged plexus choroides, dilated carotids and jugulars, dryness and hardness, or softness of its texture, adhesions of the dura mater to the frontal bone, and many other conditions of the brain itself, and accompanying disorganisation of the abdominal, and even thoracic, viscera; and although it is inferred, from a collation of all this evidence, that in disorders of the mind the brain and its connexions are usually affected, yet it is at the same time allowed that nothing of regularity obtains; and it is further uncertain how much that is seen has been cause, and how much consequence. It behoves us farther to say, in reference to morbid appearances, that the phrenological pathologists are pursuing the investigation, under the assumption that the multifarious kinds and characters of mental derangement are explicable upon the particular portion of the brain that shall have been affected. Thus excitation and delusion on one particular point, may be supposed especially to implicate that part of the encephalon which is occupied in the development of the particular passion or sentiment affected. Should future investigations confirm this principle, a great deal of what has been hitherto considered anomalies and inexplicable may be expected to be unfolded. And we think it right here to state, that one of the medical officers of a public institution for the insane has told us, that his observations harmonise with the tenets of those physiologists to whom we now allude.

Treatment.—In regard to the treatment of the insane, it should ever be preserved in recollection that an important distinction obtains between high excitement of the mind and augmented vascular action. Natural enough it is to conclude, that, in cases where we are called upon to witness the ravings of maniacal fury, a large detraction of blood from the vessels of the head is the solum remedium, the obvious and only resource. It is possible, however, for a state of the most dreadful irritation and excitement of a maniacal kind to exist and be expressed, without the blood-vessels being at all brought into that kind of state which would seem to demand bleeding, and where bleeding, indeed, will be likely to rivet and protract, rather than to mitigate and shorten, the course of the malady. It is a remarkable fact that the blood of a furious maniac for the most part exhibits, when drawn from its vessels, a state very different from that of inflammation; there is often not the smallest vestige of inflammatory buff; and it is in these cases that bleeding often does much more harm than good. We would by no means wish to assert that we consider that proposition as of universal application which objects to venæsection in mania, but we do at the very best think it problematical whether had the practice never been had recourse to, even in any one single instance, there would not have been less mischief occasioned than has been produced by its injudicious and erroneous employment. Blood-letting is principally indicated when the malady has been evidently induced through the medium of some bodily disorder; as when the catamenia have suddenly ceased after parturition, and mania has immediately succeeded; when there is much hardness, and evident velocity, about the pulsations, it is sometimes necessary to take blood, either from the head by leeches, from the neck by cupping, or from the arm by venæsection: and this demand is more especially imperious when the vascular irritation has obviously existed prior to the mental excitement.

Purging may be considered a practice of much more unequivocal and general admission than that of sanguineous depletion. With that fashionable theory we do not accord which attributes all maniacal derangement to visceral torpor and obstruction; but these obstructed states must undoubtedly have an occasional and very material influence upon the state of the mind; and such is the connexion and sympathy between the brain and stomach, that this organ and its connected viscera very often, indeed, come to be affected, in consequence of the encephalic derangement, in such a way as to render obvious the necessity of intestinal evacuations. It is impossible to lay down any rules with regard to the mode of administering purgatives which shall apply to all cases. Suffice it to say, that the saline and antiphlogistic remedies of this class seem especially indicated when much vascular irritation accompanies the maniacal derange-

ment; and that, when the hallucination is rather connected with torpor in the stomach, the vessels, and the general system, drastic cathartics are more particularly called for. Calomel is sometimes given in connexion or alternation with aloetic medicines with much benefit. But it is not possible to lay down any more than very general rules to be acted upon by the experience and good sense of the prescriber. Suffice it then to say, it is not merely a recognition of the principle that purgatives are useful, which ought to regulate the practice in these cases; but the practitioner ought to be aware of the necessity of combining, alternating, suspending, increasing, and diminishing the kinds and doses of these medicinals with an attention very different from that of mere empirical routine.

Warm bathing is another remedial process sometimes abundantly applicable and of signal utility. Attention to the cutaneous discharge is an important principle in the treatment of mental disorders; and it is in a great measure by increasing and regulating this discharge, that the practice of warm bathing proves beneficially operative.

A practice at least as old as Celsus has recently been revived under the assumption of novelty, and has been lauded as highly efficacious; it is that of causing the insane person to sit in a hot-bath with the water up to his neck and pouring cold water from a height on his naked head while in the bath.

Of the various medicinals of the nervous class we confess a considerable degree of scepticism. Camphor, opium, henbane, foxglove, nightshade, have all been lauded and derided in their turns, as they have been employed by different physicians and under different circumstances. In those cases of temporary insanity, as connected with bodily disease, in which we have found it necessary to empty the blood vessels, the immediate administration of pretty considerable doses of opium has appeared to us to be of vast advantage; but we must confess the experience we have had of any other medicinals, of the above stated kind, has not been satisfactory as to their respective virtues. In the supplementary report of the state of receptacles for the insane, there is a remarkable and well attested account of the very great powers of digitalis in calming the fury of a maniac; and an author of practical eminence delivers his opinion of this medicine in the following terms:—'Where the derangement is accompanied, and in a degree regulated, by an accelerated circulation without any other symptom of pyrexia, I have found foxglove extremely applicable. Indeed, says Dr. Cox (the author to whom we allude), I am of opinion that no case ought to be abandoned as incurable, till it has been submitted to a trial of this powerful medicine. I had a patient (he says) whose system was kept saturated as it were by digitalis for weeks in succession, whose mental wanderings seemed regulated by the state of his pulse; when the pulse was at ninety he was constantly furious, at seventy perfectly rational, at fifty melancholy, and at forty half dead. This man was at length perfectly cured by such a dose of this remedy as kept the pulse pretty uniformly about seventy.

Partly upon the same principles with digitalis, Dr. Darwin has recommended, and Dr. Cox extensively employed, rotatory motion to the extent of inducing vertigo and nausea. Haslam ridicules this practice. We repeat that all these expedients are at the best but of questionable utility. Mr. Hill, in his treatise on insanity, speaks in very high terms of emetics, especially of those composed of equal parts of tartarised antimony and sulphate of copper, according to the formula of Marryatt; and he orders these to be given every third morning for weeks together. There is so much appearance of practical good sense about Mr. Hill's book that we should be disposed to listen with some attention to any of his suggestions; but we should incline rather to the purgative than the emetic practice; always, however, recollecting the propriety of the tonic plan of treatment in connexion with purging, when a decidedly asthenic state of the system is present.

A few words remain to be said on the moral management of madness. To reason with a madman is said to prove ourselves in the same predicament with our patient. By a judicious and skilful management, reason, however, has sometimes been recalled from its wanderings, and replaced in its appropriate seat. M. Pinel, in his late work on Mental Derangement, records a curious instance of the cure of insanity, which is by no means destitute of instruction. In the Bicetre of Paris one of the lunatics supposed that his head had been taken off by the guillotine and that a new one had been fixed on his shoulders; a convalescent from lunacy conversing with this individual artfully turned the conversation upon the miracle of St. Dennis, who was said to carry his head under his shoulders and kiss it as he walked along. The insane individual appealed to his own case in order to prove the possibility of the fact, when the narrator of the story with a burst of laughter suddenly exclaimed, why how you fool could St. Dennis kiss his own head? was it with his heel you blockhead? Pinel states that this difficulty starting upon the mind of the deranged man actually operated his recovery.

Another mode in which maniacal hallucination has been dispelled, is that of indulging the sufferer in his erroneous conceptions, as in the following case related by Boerhaave.—'A counsellor at Paris retained his urine lest he should deluge the city, till his friends raised a cry of fire, and prevailed on him to lend them his assistance towards extinguishing the flames.' Vanswieten mentions the case of a man who conceived that his legs were made of glass, till the maid servant threw a block of wood upon his shins, which excited pain, and with it such indignation, that, forgetting the transmutation of his limbs, he pursued her to take revenge. Thus convinced the conceit left him, and, by proper exercise, he perfectly recovered.

The following case is from Dr. Cox, and similar cases in kind, if not in degree, are falling daily into the hands of the medical practitioner The use which may be made of them is this; that by a justifiable acquiescence in the reality of alleged feelings, the physician may oftentimes be more successful in dispelling such hallucina-

tions, than by endeavouring the hopeless task of convincing his patient of the mere imaginary nature of his sufferings. 'Mr. ———, aged twenty-five, of a fair complexion, though dark hair and eyes, of exemplary morals and most amiable manners, was fond of anatomy, and had dissected some few animals; very desultory in his studies, but had read some medical authors with much attention, and was in the constant practice of quacking himself. Though no apparent alteration took place in his countenance, yet he constantly complained; and all his attention was confined to his health, which at length actually rendered him incapable of any exertion, either bodily or mental. After the repeated and anxious enquiries of his friends, it was discovered he believed himself affected with syphilis, contracted not by any unfortunate connexion, but from sitting on the same seat with an infected person. Deaf to all reasoning and attempts to prove the impossibility of the disease being propagated in such a way, his case was referred to some medical man of whom he had read or heard; and he, being previously instructed, pronounced it venereal, sent a prescription which very soon dissipated the absurd idea, and restored him to himself, his friends, and his family.'

To revive former impressions, and thus to break the chain of diseased association, will sometimes be an advisable attempt. On this account, and with this view, it will of course be important to ascertain the previous habits, tastes, feelings, propensities, and occupations of your insane patient. 'In a military maniac,' says a modern author of much acumen, 'I once witnessed the notes of a shrill pipe managed with some address first awaken the attention, then occasion interest, as was obvious by his animated looks, and beating time; at length, by varying the air according to the observed effects, produce the most pleasing sensations. It at length brought back some very impressive recollections, created entirely new trains of thought, and seemed to correct the errors of intellect. Though he had not left his bed for weeks, nor spoken a single word during that time, and had been supported entirely by force, he now arose, dressed himself, and without any other remedy but gentle tonics, returned to his former habits of neatness and rationality; advancing gradually to perfect recovery.'

But we might occupy a great number of pages were we to go over the records of individual cases, in which either by design, or by accident, a forcible impression upon the imagination or feelings of maniacs, had succeeded in dispelling the deranged idea, either for a time or for a continuance. The reader is not to suppose that we mean to assert that this task of curing insanity, by these means, is of easy accomplishment; but it is always right of course to be armed at all points, and to make accidental occurrences subservient to practical instruction.

With regard to the question of confinement, and personal restraint, it is difficult to say any thing which shall apply universally. Certain it is, as a modern author has stated, that nothing is more calculated to make a man mad, than the idea that he is thought so by others; on the other hand, however, we feel convinced that incipient insanity has often been prevented from breaking out into overt acts, and from becoming confirmed and irremediable, by an early and judicious personal restraint. We recollect hearing Dr. Aikin say, that some of the most valuable articles in his biography were penned in a mad house, and that the gentleman who wrote them was so convinced himself of the necessity of his own confinement, that when he found himself conscious of approaching insanity he voluntarily submitted himself to the custody of keepers, and the regime of a mad-house, before the malady had come to such a height as to deprive him of the power thus to exercise his will. We must confess, for ourselves, that in the generality of cases in which we found the marks of insanity pretty fairly made out, even before the malady should have become thoroughly established, we should rather incline to give our probatum for placing the individual under those circumstances which would prevent the possibility of his inflicting injury either upon himself or others; and which, we are convinced, although it may bear the appearance of cruelty, is often, on the contrary, the height of mercy. We do not say that we would consign every nervous or melancholic man to the stigma of madness and the confines of a mad-house; nor, we hope, is it at all necessary for us to say, that every thing in the shape of restraint or control, beyond what is necessary to the well-being both of the patient and those about him, is to be deprecated as equally absurd and inhuman. 'It has been recommended,' says an author to whom we have more than once referred in the present paper, 'by very high authority, to inflict corporal punishment upon maniacs with a view of rendering them rational by the impression of terror; what success may have followed such disgraceful and inhuman treatment, I have not yet learned, nor should I be desirous of meeting with any one who could give me the information. If the patient be so far deprived of understanding as to be insensible why is he punished? such coercion, setting aside its cruelty, is manifestly absurd; and, if his state be such as to be conscious of the impropriety of his conduct, there are other methods more mild and effectual.'

411. *Night Mare.* Oneirodynia.—It is rather curious that Dr. Cullen should have classed this affection under the head of vesanic disorders, which is only thus entitled to a situation among these ailments from the circumstance of the imagination being morbidly excited in them. The oneirodynia of nosologists is divided into active and passive; in the first the irritative and imaginative ideas excite the patient to walk in his sleep; the second is characterised by a sense of oppression upon the breast, as if a heavy load were lying upon and threatening the individual with suffocation.

Dr. Darwin in his Zoonomia introduces the following ingenious observations on the subject of sleep, which were transmitted to him in a letter from Dr. Currie; and we shall here transcribe them with the comments of Dr. Darwin, and the further remarks of the latter on the subject of night mare.

'Though rest in general perhaps renders the healthy pulse slower, yet, under certain circumstances, the contrary is the truth. A full meal without wine, or other strong liquors, does not increase the frequency of my pulse, while I sit upright, and have my attention engaged. But if I take a recumbent posture after eating, my pulse becomes more frequent, especially if my mind be vacant, and I become drowsy; and, if I slumber, this increased frequency is more considerable with heat and flushing.

This I apprehend to be a general truth. The observation may be frequently made upon children; and the restless and feverish nights experienced by many people after a full supper are, I believe, owing to this cause. The supper occasions no inconvenience whilst the person is upright and awake; but when he lies down and begins to sleep, especially if he does not perspire, the symptoms above mentioned occur. Which may be thus explained in part from your principles. When the power of volition is abolished the other sensorial actions are increased. In ordinary sleep this does not occasion increased frequency of the pulse; but, where sleep takes place during the process of digestion, the digestion itself goes on with increased rapidity. Heat is excited in the system faster than it is expended; and, operating on the sensitive actions, it carries them beyond the limitation of pleasure, producing, as is common in such cases, increased frequency of pulse.

It is to be observed that, in speaking of the heat generated under these circumstances, I do not allude to any chemical evolution of heat from the food in the process of digestion. I doubt if this takes place to any considerable degree; for I do not observe that the parts incumbent on the stomach are increased in heat during the most hurried digestion. It is on some parts of the surface, but more particularly on the extremities of the body, that the increased heat excited by digestion appears, and the heat thus produced arises, as it should seem, from the sympathy between the stomach and the vessels of the skin. The parts most affected are the palms of the hands and the soles of the feet. Even there the thermometer seldom rises above 97° or 98°, a temperature not higher than that of the trunk of the body; but three or four degrees higher than the common temperature of these parts, and therefore producing an uneasy sensation of heat, a sensation increased by the great sensibility of the parts affected.

That the increased heat excited by digestion in sleep is the cause of the accompanying fever, seems to be confirmed by observing that, if an increased expenditure of heat accompanies the increased generation of it (as when perspiration on the extremities or surface attends this kind of sleep), the frequent pulse and flushed countenance do not occur, as I know by experiment. If, during the feverish sleep already mentioned, I am awakened, and my attention engaged powerfully, my pulse becomes almost immediately slower, and the fever gradually subsides.'

From these observations of Dr. Currie it appears, that, while in common sleep the actions of the heart, arteries, and capillaries, are strengthened by the accumulation of sensorial power during the suspension of voluntary action, and the pulse in consequence becomes fuller and slower; in the feverish sleep above described the actions of the heart, arteries, and capillaries, are quickened, as well as strengthened, by their consent with the increased actions of the stomach, as well as by the stimulus of the new chyle introduced into the circulation. For the stomach, and all other parts of the system, being more sensible and more irritable during sleep, and probably more ready to act from association, are now exerted with greater velocity, as well as strength, constituting a temporary fever of the sensitive irritated kind, resembling the fever excited by wine in the beginning of intoxication; or in some people by a full meal in their waking hours.

On waking, this increased sensibility and irritability of the system ceases by the renewed exertions of volition; in the same manner as more violent exertions of volition destroy greater pains; and the pulse in consequence subsides along with the increase of heat. If more violent efforts of volition are exerted, the system becomes still less affected by sensation or irritation. Hence the fever and vertigo of intoxication are lessened by intense thinking; and insane people are known to bear the pain of cold and hunger better than others; and, lastly, if greater voluntary efforts exist, as in violent anger or violent exercise, the whole system is thrown into more energetic action, and a voluntary fever is induced, as appears by the red skin, quickened pulse, and increase of heat; whence dropsies and fevers with debility are not unfrequently removed by insanity.

Hence the exertion of the voluntary power in its natural degree diminishes the increased sensibility, and irritability, and probably the increased associability, which occur during sleep; and thus reduces the frequency of the pulse in the feverish sleep after a full meal. In its more powerful state of exertion it diminishes or destroys sensations and irritations, which are stronger than natural, as in intoxication, or which precede convulsions, or insanity. In its still more powerful degree the superabundance of this sensorial power actuates and invigorates the whole moving system, giving strength and frequency to the pulse, and a universal glow both of color and of heat, as in violent anger, or outrageous insanities.

If, in the feverish sleep above described, the skin becomes cooled by the evaporation of much perspirable matter, or by the application of cooler air or thinner clothes, the actions of the cutaneous capillaries are lessened by defect of the stimulus of heat, which counteracts the increase of sensibility during sleep, and the pulsations of the heart and arteries become slower from the lessened stimulus of the particles of blood thus cooled in the cutaneous and pulmonary vessels. Hence the admission of cold air, or ablution with subtepid or with cold water, in fevers with hot skin, whether they be attended with arterial strength or arterial debility, renders the pulse slower; in the former case by

diminishing the stimulus of the blood, and in the latter by lessening the expenditure of sensorial power.

The night-mare is an imperfect sleep, where the desire of locomotion is vehement, but the muscles do not obey the will; it is attended with great uneasiness, a sense of suffocation, and frequently with fear. It is caused by violent fatigue, or drunkenness, or indigestible food, or lying on the back, or perhaps from many other kinds of uneasiness in our sleep, which may originate either from the body or mind.

Now, as the action of respiration is partly voluntary, this complaint may be owing to the irritability of the system being too small to carry on the circulation of the blood through the lungs during sleep, when the voluntary power is suspended. Whence the blood may accumulate in them, and a painful oppression supervene; as in some hæmorrhages of the lungs, which occur during sleep; and in patients much debilitated by fevers.

Great fatigue with a full supper and much wine, I have been well informed by one patient, always produced this disease in himself to a great degree. Now the general irritability of the system is much decreased by fatigue, as it exhausts the sensorial power; and, secondly, too much wine and stimulating food will again diminish the irritability of some parts of the system, by employing a part of the sensorial power, which is already too small, in digesting a great quantity of aliment; and in increasing the motions of the organs of sense in consequence of some degree of intoxication, whence difficulty of breathing may occur from the inirritability of the lungs.

This explains an apparent paradox, why people who are feeble digest their dinners best if they lie down and sleep, as most animals do, when their stomachs are full. Yet many weak people sleep very uneasily after a large supper. If the debility of the patient be not very great, and the dinner he has taken be moderate, the suspension of voluntary action during sleep prevents the expenditure of so much sensorial power, which may be employed on the actions of the stomach, and thus facilitate the digestive process. If the patient be further exhausted as in the evening, or his debility greater, and sleep ensues after a copious or stimulating supper, so much sensorial power will be exerted on the actions of the stomach for digestion, that the circulation of the blood through the lungs will be impeded from the diminished irritability to external stimuli, and the absence of volition, as in the incubus, and somnus interruptus.

M.M. To sleep on a hard bed with the head raised. Moderate supper. The bark. By sleeping on a harder bed the patient will turn himself more frequently, and not be liable to sleep too profoundly, or lie too long in one posture. To be awakened frequently by an alarm clock.'

The cause of sleep walking or active oneirodynia, is exceedingly obscure. An ingenious essay published some time since (if we recollect right, in one of the volumes of Transactions from the Dublin College of Physicians) endeavoured to establish the phrenological datum of separate faculties and localities of the brain from the phenomena presented by the sleep walker; the doctrine advocated in the paper was this, that the waking condition of one part of the cerebral mass in connexion with the torpid state of the others impels to sleep walking from the circumstance of those faculties being still locked in sleep which if awake would correct the impulse of the one awake and put it under the ordinary control of regular condition.

One very remarkable feature in sleep walking is the accuracy with which things are accomplished, demonstrably without the exercise of those perceptions which we are accustomed to think absolutely necessary to be in exercise for the accomplishment of the purposes effected; it would seem as if the whole sentient power were for a time accumulated in one organ, and that thus a person, by becoming all ear or all touch, made up as it were for the want of other senses. We know, indeed, that this law in some measure obtains under circumstances of permanent suspension or abolition of one of the senses; the nervous power which would have been expended in the exercise of this or of that sense is directed into one which still remains unimpaired, and the latter becomes in the same ratio acute; thus magnitude and form are judged of by a blind man, through the organ of hearing, and an individual being without, or having lost, his sight is often able to determine the number of persons present in a room, merely by the acuteness of smell. Habit and exercise we are aware explain a good deal of this law, but they do not wholly; and the sleep walker, as we above intimated, appears to illustrate it in a remarkable manner. As a matter of curiosity, and with a view to exemplify the above positions, we shall extract the following interesting accounts which Dr. Beddoes has copied in his Hygëia from foreign publications; and remarkable, or inexplicable as they appear, they are too well authenticated to allow us to doubt of their truth.

'In the Encyclopedie, under the article SOMNAMBULE, there is an observation which shows a remarkable suspension of one series of affections, while others, the most intimately connected with them, were going on. The archbishop of Bourdeaux was at college with a student subject to walking in his sleep. On planting himself from curiosity in the student's chamber, so as to ascertain his motions, he observed the young man sit down to compose sermons, which he read page by page as he committed them to paper, if it can be called reading when no use was made of the eyes. On being dissatisfied with any passage, during the recitation, he crossed it out and wrote the correction with much accuracy over it. The writer of the article saw the beginning of a sermon in which was the following amendment. It stood at first ce divin enfant. On revisal it struck the student to substitute adorable for divin. So he struck out the former word, and set the latter exactly above it. But, remarking that the article ce could not stand before adorable, he very nicely set a *t* after ce, and it then stood, cet adorable enfant.

To satisfy himself that the somnambulist, in all these operations, made no use of his eyes, the archbishop held something under his chin, suffi-

cient to intercept the view of the paper on which he wrote. But he wrote on without being interrupted by this obstacle in the way of his sight. To discover how the night-walker knew the presence of objects, the archbishop took away the paper on which he wrote and pushed other papers under his hand. Whenever they were of unequal size the student was aware of the change; but, when they were equal, he wrote on, and made corrections on the spots corresponding with his own paper. And it was in this way that possession was gained of some of his nocturnal lucubrations. Among other manuscripts, which the archbishop put into the hand of the encyclopædist, are musical pieces written with tolerable exactness.

One night, having dreamed that he was beside a river into which a child had fallen, he went through all the actions tending to its rescue, and with teeth chattering, as from cold, asked for brandy. None being at hand, a glass of water was given him instead. But he immediately remarked the difference, and with greater impatience demanded brandy, saying he should die if none were given him. Brandy was therefore now brought. He took it with pleasure, and said, as he smelled to it, that he found himself already better. All this time he did not awake, but, as soon as the paroxysm was over, lay down on his bed and slept very composedly.

In some cases the susceptibility of visual impressions has undoubtedly remained, because the somnambulist has been sensible to some present objects of sight, though not to others. This partial attention seems clearly to have existed in the case described in Darwin's Zoonomia, since the patient drank tea, when it was set before her, and smelt to a tuberose, which last action might however have arisen from accurate recollection of the place where it stood. In the remarkable instance, frequently observed and described at large by Porati, the same circumstance occurred. A young man in his employ, of the name of Castelli, who had often before suffered from nervous affections, took a candle and lighted it. Instead of going to bed, as was supposed to be his intention, he went down stairs, reached a book from a shelf in his master's study, and began to read. Porati several times desired him to go to bed, but received no answer, upon which he took away the light. Castelli upon this got up, and opened the window, observing—it is cloudy, we shall have rain to day. The master now replaced the light, and Castelli immediately walked up to it, and began to read aloud. The people of the house collected round him, but he observed no one. They called to him, but he did not hear. The light being again removed, he got up, rubbed his eyes, and said 'I am not well; I must go out into the air.' He accordingly went into the apothecary's shop belonging to his master. Here, other methods having been fruitlessly tried to rouse him, some spirit of hartshorn was held to his nostrils, when he immediately sank to the floor and fell into convulsions. After some minutes he had a tetanus, or universal spasm of his muscles, which by degrees relaxed, and he slept. Presently he awaked, as out of a sound sleep, but knew nothing of what had passed.

Another time he fell asleep in the shop, but had continued only a short time in that state, when he opened his eyes, muttered a few words lighted a candle, went into the study and began to read. He was at this time studying French, and had to translate a passage out of the Italian. He ceased reading, took up the dictionary, and made his exercise, as well as if he had been awake.

They snuffed out his candle, when, without noticing other candles that were burning in the room, he went into the kitchen and struck a light, by which he rekindled his own candle and set to his task again. It was snuffed out again. He shut the window, as supposing the wind had blown out his candle, which he lighted anew; when Porati blew it out. He now grew impatient. He stirred the embers, took some matches in his hand, and said—'Is that fire, or is it not?' He lighted the candle and went into the study, where he took a dispensatory, examined by it some plants that stood ready for distillation, and found one right after the other. Porati now spoke to him about the plants. He immediately heard and answered as rationally as if he had been awake. He then fell asleep, soon awoke, and was sent to bed

On another occasion a remark he made, on a book which he was reading, excited in one of his comrades a suspicion that he was feigning. To ascertain this, the comrade held the flame of a candle to his hand, but he did not withdraw it. Next morning he complained of a pain in the place, but did not know how it came

He was repeatedly observed not to know any person or thing but what coincided with his passing train of ideas. When he went into the shop, if faulty recipes were brought to him, he would soon detect the error, but did not know the persons who brought them, though they were his own comrades, but took them for servants who came for medicines. He often tried to light a candle at a lamp standing under a glass bell, of which he was not aware; and it was observed that he could not distinguish two powders of which one had a strong smell and the other was without any. It was accidentally discovered that the waving of a fan threw him into a quiet sleep, and this expedient was frequently employed to stop him when he attempted to do what his master did not wish. The effect of the moving air was to arrest him suddenly, upon which he would sink down and sleep a short time, but his paroxysm went on afresh afterwards.'

We must be better acquainted with the rationale of function, and know more of pathology than we now do, before we can explain these and other curious and remarkable susceptibilities and peculiarities of the sentient and percipient organisation. They must, however, be considered as objects of considerable interest; and perhaps future pathologists may come nearer to a free exposition of their theory than at present is generally conceived to be possible.

412. Class 3. *Cachexia.*—The disorders which should be properly included under this head, would be those which according to the doctrines of the humoral pathology, and according, indeed, to vulgar phraseology and opinion, are considered

indications of a bad habit, as it is expressed, which means, if it means any thing, that the humors of the body, instead of being what they ought naturally to be, have undergone some change either in their physical or chemical condition, which is inconsistent with a state of absolute health. Thus should a wound, instead of healing kindly and regularly, show an indisposition to come to this favorable termination, without any thing in the character of the wound itself, or in exterior circumstances, to account for the tardiness; or should a chronic eruption break out on the surface of the body without being excited by imparted virus, or independently of any pyrexial irritation, the individual subject to such complaints and conditions would be considered in a bad habit of body.

But these vague sort of explanations do not satisfy the pathological precision of present times, and we look for something more satisfactorily explicative than this terminology supplies. It must, however, be confessed, and we have already intimated the same thing in the proem to the present article, that the physiognomy and character of some chronic disorders is not easily explained upon any other hypothesis than those which the humoral doctrines present to us. As, however, these cachectic disorders are for the most part disorders of the assimilating and absorbing functions, it will be consistent with what we have already done in reference to the pyrexial and nervous classes of ailments, to engage in a preliminary sketch of the more prominent and primary disorders to which the absorbents, as a distinct system are obnoxious; a distinct system, however, we should hardly say; for, as it has been expressed by a modern author, 'whilst we thus survey detached portions of the animal economy, and examine the disorders to which each part is principally subject, it must be confessed that nature has not left them independent of each other. Nay, so far is she from having established an empire within an empire, that, with astonishing contrivance and unity of design, she has made each part subordinate to the rest; and hence it is that, if one is principally affected, the other sympathise and are drawn into action by consent.'

This idea is beautifully expressed by Hippocrates, when he compares the body to a circle in which we can find neither the beginning nor the end, and then remarks that the same observation will hold good respecting its diseases.

Yet, adds our author, notwithstanding the efforts of nature to relieve herself are thus combined, they require for the sake of distinctness to be separately viewed, and, to cure diseases, attention must be turned towards the system chiefly affected, whether the arterial, the nervous, or the absorbent. And it is under this feeling that we now engage in considering generally the pathology of the absorbents.

It is well known that the celebrated Brown, as we have indeed before observed, attempted so great a simplification of vital powers and diseased habits, as to place every thing to the account of one principle pervading the frame, which he named excitability; but, were there no other error in his system, this single fact would be sufficient to subvert it from its foundation, viz. that different parts of the frame are under the distinct influence of different impulses. Thus those agents which excite one series of actions in the body will at the same time suppress others; for instance, nausea, or inaction of the stomach, occasions a temporary augmentation of the powers of absorption. The known varieties, too, of constitutional susceptibilities are all at variance with the above principles. While then we avoid falling into the vulgar errors connected with and derived from the humoral pathology, we must at the same time recollect that in different individuals, and at different periods of life, there is immense variety of kinds as well as degrees of susceptibilities and excitants.

Dr. Heberden observes, and it is a curious as well as important fact in the animal economy, that the lymphatic glands of the neck, groin, axilla, and mesentery, are more especially subject previous to the period of puberty to disordered action. At the time of puberty the pulmonary organs are principally obnoxious to disease, and in more advanced life the uterus and breast in females, and the prostate and other excretory glands in males, are the seats of morbid affection. Now these facts are susceptible of something like the following explanation. We have already stated that the evolution of organs is different at different stages of life. In infancy, and previously to the development of sexual peculiarities, those lymphatics and absorbents are chiefly called into action which are concerned more properly and especially in the growth of parts. To the head, the mesentery, and the extremities, is the blood now directed in a greater proportion; the deposition of calcareous matter forming bone is at this period proceeding with rapidity. Absorption is necessarily required and effected in the same ratio; and, in those constitutions which are characterised by constitutional laxity in the fibres of the exhalant and absorbing vessels, disease will most readily appear in these parts, which are now subject to the greatest degree of irritation.

The lungs at the age of puberty, as is indicated by the alteration of the voice and other circumstances, undergo a very material change. The osseous portions of the extremities and of the head being now rendered nearly complete, the growth and changes of these parts proceed more leisurely and tardily; the principal impetus of the blood is directed into other channels, new determinations (as it is technically expressed) arise, and constitutional excitement is directed from the parts above mentioned to the lungs. Hence the very frequent occurrence of pulmonary disorganisation at the time when the constitution is about to assume fully its sexual character; and hence the more usual appearance of a tendency to such disorganisation in those habits which are called scrofulous.

Individuals of such temperament are in after life subject to diseases of the organs above mentioned, in consequence of all weak parts being made more than ordinarily obnoxious to organic derangements by the abstraction of their accustomed stimuli. The breasts are no longer excited to the secretion of milk, the offices of the prostate

gland and seminal vessels cease, the uterus does not now acknowledge its former stimulus; and these organs, always more or less liable to disordered action, with difficulty resume their original state of inactivity without falling into actual and positive disease.

That condition of absorbent disturbance and derangement which constitutes the disease named by authors tabes mesenterica, as the source and origin of so many others, demands to be primarily considered.

Tabes mesenterica, or mesenterica atrophy, is characterised by the following symptoms. A prominence and hardness of the abdomen, with sometimes irregular and knotty protuberances, with an emaciation of the limbs, and a paleness of the countenance, unless when it is lighted up with a hectic flush. The bowels are extremely irregular, now constipated, and now in a state of more than healthy looseness: the stools, however, are never of a good appearance and consistence, they consist of slimy and mucous matter in place of proper fæculent discharges; the temper of the little invalid (for this is a disorder of infancy) is made peevish and fretful; when the malady arises to any height the child moans piteously, and cannot be brought to notice surrounding objects. It seems to be wrapped up in itself and in its complaints. After the state has continued some time, the limbs will not only be flabby and feeble, but they will become of a rickety deformity, and the patient is invariably taken off its legs, as the persons about children are in the custom of expressing themselves.

Now with a recollection of the functions and office of the lacteal absorbents and glands, and with a small knowledge of the physiology of adjacent organs, the rationale of the above mentioned appearances does not appear very difficult to trace. The tumefaction of the abdomen has some connexion with retained matter in the intestines, but is more especially connected with a disordered condition of the mesenteric glands. It will be proper here to observe, that this glandular enlargement is not, as might be supposed, occasioned by a mechanical obstruction to the passage of chyle, but is dependent upon a disordered action of the glands themselves. There is in fact less than the ordinary quantity of digested aliment in the mesenteric passages during this derangement of parts. Chyle is not duly secreted or manufactured, and on this account, not from a mechanical impediment to its progress through the lacteals, it is that a due quantity of aliment is not given to the blood; and hence the paleness and weakness of the subject of the complaint.

The torpid state or irregular action of the bowels, and the discharge of slimy, in place of proper fæculent evacuations, appear to have somewhat of a complicated origin.

For the due digestion, separation, and assimilation of the aliment, it is not merely necessary that a due action be preserved in the muscular fibres of the stomach, intestines, and lacteals, but it is at the same time requisite that the offices of what are called the assistant chylopoietic viscera be performed without interruption. For due and complete digestion and chylification the liver must pour out its bile, and the pancreas its peculiar secretion. It is further necessary that not only the quantity, but also the quality of these fluids be duly maintained. Now in that torpid state of the lymphatic or absorbent system which occasions tabes mesenterica, there is not merely a diminished quantity of biliary and pancreatic secretions, but such diminution is accompanied by a deficient stimulant property in these secretions, since from the inactivity of the absorbents their aqueous portions are not reabsorbed. Thus the duodenum receives them in a dilute weak state; a state in which they are incapable of either properly assisting in the requisite solution or preparation of the nutritious from the fæculent portions of the aliment, or of stimulating the irritable fibre of the intestine in order to eliminate the latter. Hence the discolored, slimy, and viscous appearance of the stools in children laboring under tabes mesenterica; and hence the irregularity as to time in which the alvine excretions are discharged.

With regard to the impeded growth, flabbiness of the flesh, paleness of the face, and ricketty deformities that in a greater or less degree arise out of this state of things, we have only to advert to the general laws of the absorbent system for an immediate explanation of them. During infancy, the principal office of the exhalant termination of arteries is the deposition of calcareous matter forming bone. Now, when the blood from which this secretion of osseous substance is obtained becomes deprived of its source of supply; when the chyle is, from the state of the mesenteric vessels, prevented from being conveyed to the blood-vessels, the lymphatic arteries are by consequence bereaved of their wonted stimulus to action; the earth of bone (principally phosphate of lime) fails of being duly deposited; the limbs, instead of gradually acquiring firmness and strength, remain soft and yielding; rickety deformity presents itself, the want of a proper quantity and consistency of blood occasions paleness, and every function is either torpid or irregular in its display.

Such then is shortly the history and rationale of mesenteric atrophy; and scrofula, which has been treated as a distinct disorder, may perhaps be represented rather as the cause for the most part of other diseases, than a disease itself. Thus it is a scrofulous weakness in the lacteal and lymphatic vessels that causes tabes mesenterica; and this last may be looked on as the root of almost all other diseases of lymphatic debility. In some cases, however, scrofula appears as a decided tendency in the habit, without occasioning other diseases, and sometimes there are inflammations and ulcerations in different parts of the body to which we can give no other name than the general one of scrofula. The marks of a scrofulous tendency, and the general characters of these scrofulous irritations, it therefore behoves me more briefly to point out. A fine transparent skin, a full blue eye, and an extraordinary whiteness of the teeth, are the signs of the scrofulous diathesis which are most usually pointed out by authors; but it has been with

propriety remarked, by other writers, that a dark eye and dark hair are frequently connected with the scrofulous tendency; and when that is the case an apprehension of its consequences upon the system would seem even to be better founded than in the former case, since the lymphatic and glandular irregularities to which it disposes are of a more torpid, more fixed, and more deep-seated kind. Consumption of the lungs creeps on insidiously upon these subjects: insidiously since there is not that external disposition to lymphatic irritation in so great a degree as in the more obviously scrofulous. In these the lymphatic glands in the neck, in the axilla, and indeed in all parts where they are found in abundance, are very apt to take on a diseased state, and when from mere inflammatory irritation they form into open ulcers or abscess, these ulcerations are called scrofulous. Now one very remarkable characteristic of these tumors, when they come to ulcerate, is, that they do not pour out pus, properly so called, as humors of other kinds and other parts do, but a sort of curdy chalky-like matter issues from the wound, which John Hunter has described as the coagulating lymph, deprived of its serum; it would seem however to be a peculiar secretion, occasioned by the condition of the lymphatic vessels when thus the subject of scrofulous irritation. Scrofulous ulcerations are exceedingly difficult to heal, and will often continue for months in an indolent kind of state with irregular edges, indeed when they tend inwardly upon the bones they last sometimes in this state for years, and come to produce erosions, and exfoliations, and caries, the history and progress of which will fall to be detailed in the article SURGERY.

The cure of scrofula is generally directed to the treatment of its particular manifestations; but we shall have occasion to offer a few remarks on this head in another place.

Dropsy is another affection which has to do in an especial manner with the absorbents. This disease is constituted by a collection of lymph into cavities, which, not being taken up and returned into the blood vessels, remains as extraneous matter, and causes the swellings by which the complaint is characterised. The different kinds and species of dropsy, when they arise principally from inflammatory irritation, and when they are rather the result of pure and direct debility in the exhalant and absorbent vessels, will be canvassed forthwith under the head of *Dropsy*. It may be here sufficient to remark that in no case, either of general or local dropsy, can the malady be established without an absorption disproportionate to the exhalation, and that consequently dropsies have a singular right to be classed as lymphatic diseases.

Of rickets scarcely any thing further need be said than that it is almost the same affection with mesenteric atrophy; and how the ricketty growth of bones becomes established in that affection namely, from the blood-vessels not receiving their due supply of good chyle, we have already endeavoured to explain.

Mollities ossium, or softness of the bones; in which indeed they become so deprived of their osseous matter as to lose all the character of bones, is a disease not of very ordinary occurrence. When, however, it does take place it must necessarily be in the way of either deficient action in the exhalants, or excessive, or rather disordered, action in the absorbents, by which either a disproportionate quantity of osseous matter is taken up from the bones and reconveyed into the circulation, or there is an insufficient secernment of this substance from the blood-vessels.

But perhaps we cannot better continue this preliminary view of absorbent susceptibility and peculiarity than by an extract from the elements of Therapeutics by Townsend, a work, which although faulty in many particulars, and in the one of a too hasty reception of the pneumatic doctrines which were prevalent at the time the author wrote, yet contains much of what is correct in pathology, and useful in practice.

Nothing in nature, says Mr. Townsend, can be more worthy of admiration than the vital action of the absorbents; and it is curious to observe that their activity continues unimpaired whilst sensation and the animal functions are perfectly suspended. This will be evident if we consider that, during sleep, the bronchial mucus is much thickened, and that both the urine and the fæces show the continued progress of absorption.

In our wonderful machine, to prevent friction and adhesions, it is required that vapor should be interposed between contiguous parts, more especially if either of them is designed for motion. This the excretories provide; but, as it must be frequently renewed, absorbents are incessantly at work, to convey it back into the mass of circulating fluids. Dr. Musgrave injected twenty-four ounces of water into the thorax of a dog, and in five days the whole was taken up by the absorbents, for the breathing became as free as it had been before this water was introduced into the chest.

In case of dropsy, nature, by means of the absorbent system, makes wonderful efforts to relieve herself.

John Hunter relates the case of a lady, with swelled legs, who made little or no urine, and was so weak that she could scarcely articulate. She dozed incessantly, and had no desire for food. Her pulse was hardly to be felt, her feet and all her extremities were cold, yet, within thirty-six hours of her death, the whole water in her legs and thighs was absorbed, her urine was increased, and, about ten hours before she died, her legs and thighs were as small as ever. Hoffmann, in confirmation of what is said by Aretæus, assures us, that he has seen many perfectly cured by a spontaneous and long continued diarrhœa. But what is most surprising is, a case recorded by Fernelius, Pathol. lib. 6, in which ascites was relieved by the approach of the menstrual period by a profuse discharge of water, which continued for two days; and when, in the interval of menstruation, the serous fluid had been collected, it was the next month entirely discharged by the uterus.

Some kind of vessels, as I have stated, are employed to take up the roscid lymph from the ventricles of the brain; but the office assigned to the common cellular absorbents is twofold; for they not only imbibe the aqueous fluid from the

reticular part of the cellular membrane, but, when it is needful, they absorb the animal oil from the little bags in which it is deposited, and convey it wherever it is wanted for the purposes of life.

When there is any extravasation either of lymph, of serum, or of blood, they remove it; and when extraneous matter gets into the system, if this proves injurious, they quickly go to work; or, if any part is either dead or useless, it proves a sufficient stimulus to excite their action.

In cases of gangrene, both sloughing and exfoliation are produced by the absorbents, and thus a separation is made between the living and the dead.

When whole parts are to be removed, as useless, without producing solution of continuity in the surrounding parts, this can be accomplished only by the action of the absorbents. It is thus the thymus gland, the ductus arteriosus, the membrana pupillaris, are obliterated, and thus also the fangs of diseased teeth, with their sockets, are quietly destroyed. It is by this process that aged women lose their breasts, when these are no longer needful. When the cataract has been extracted, the absorbents take up the capsule, and frequently, more especially after couching, they carry off the cataract itself. The diseased testicle is removed by them, and sometimes in cases of necrosis they devour the bone itself. It is by this process that schirrous tumors are removed.

Du Hamel has demonstrated, by his experiments, that the earthy parts of bones, on which they depend for solidity and strength, are unremittingly renewed, whilst the absorbents carry off, and exhalant arteries as constantly deposit calcareous matter. This discovery he made by feeding animals alternately with common food, and with this strongly tinged by rubia tinctorum; in consequence of which their bones were variegated red and white. But when he had ceased to give the madder for six weeks this redness vanished.

When either extraneous bodies or dead parts, which cannot be absorbed, cause irritation in the system, the absorbents destroy the intermediate living parts between the offending matter and the nearest external surface of the body. It is by this process that nature frequently relieves herself in cases of necrosis and of extra-uterine conception. And it is thus that pus, when produced internally, exfoliated bones, and all extraneous matters, are discharged. But sometimes it happens that, whilst the ulcerative process is destroying the inside of a bone, the ossifying process makes addition to its outside, and the bone increases to a prodigious size; but in the end the ulceration on the inside gets the better, and the matter makes its escape. Whenever incysted tumors are formed in the cellular membrane, the whole substance between them and the skin is in process of time taken up by the absorbents, and then inflammation commences to produce a quicker absorption, which borders often upon ulceration. It is thus that the tumor is exposed. John Hunter mentions a case which came under his inspection, in which a tumor, formed upon the brain, excited to such a degree the action of the absorbents, that without ulceration they carried off the opposing portions of the dura mater, of the scull, and of the scalp.

When there is offending matter in the system, which cannot be expelled by the usual outlets, the absorbents convey it back into the mass of circulating fluids to be thrown out by the emunctories. Thus it is evidently in jaundice; for the bile, being prevented from passing by the common duct into the intestines, is taken up by the absorbents and secreted by the kidneys. And, when mania and melancholia are relieved by cuticular eruptions, we are probably indebted to the absorbents; for upon all occasions they are ready to assist nature in her efforts to relieve herself. John Hunter mentions a young man who had a large bubo in the bottom of his belly which, having suppurated and being on the point of breaking, was suddenly absorbed. While this process was going on he observed his urine wheyish and thick, as it was coming from him; but this went off entirely when the bubo had subsided.

Since the absorbents act, not by capillary attraction, but with vital energy, which is liable to increase and diminution, it is evident that their activity may be either deficient or excessive. But whatever produces either direct or indirect debility lessens the action of the absorbents, because the vital energy is injured equally by both.

I. Direct debility is induced, *α*. By deficiency of wholesome nutriment, when it fails either in quantity or quality. This we observe among people who live chiefly on the legumina, peas and beans, or on other unfermented vegetables, with dried, smoked, and salted fish, as in Holland; on cucumbers, melons, pompions, and other vapid fruits, as in the watered provinces of Spain; or on bread, water, tea, as in some parts of England. *β*. By deficiency of exercise, more especially when the indolent and inactive spend most of their time in sleep. *γ*. By sudden and profuse evacuations. *δ*. By impure air with excess of humidity. *ε*. By such poisons as are directly sedative, among which I am inclined to reckon bile and the menstrual secretion retained.

II. Indirect debility is induced by excitement either violent or long continued, and therefore by such poisons as are indirectly sedative, that is, whose first operation is stimulant. We have seen, by the experiments of the Rev. Dr. Hales on vegetables, that their vital energy constantly accumulates during the night, and is to a certain degree exhausted by the stimulus of light and heat before the middle of the day. And we observe, not here particularly to mention heat, that wine, spices, spirits, have precisely the same effect on the absorbents, as may be seen in gluttons, and in drunkards whose spleen, pancreas, and liver are frequently discovered to be schirrous.

The consequence of defective action in the absorbents must be disease, such as obesity, indolent tumors, aqueous accumulation, and herpetic eruptions.

Excessive action of the absorbents produces atrophy, and may arise from either general excitement, as in acute fevers, or partial stimulants. The stimuli may be irritating substances, such as

pears passing constantly over the cheeks; or pressure, whether by external objects, by indolent tumors, by pus, or by aneurisms, all which cause the lymphatics to absorb, not only membranes and muscular fibres, but the bones. Thus, in case of a large aneurism of the aorta pressing against the back-bone, the artery is first absorbed where it comes in contact with the bone, and continues to waste till the whole is taken up, after which the bone itself is soon consumed; but, as the surrounding parts unite by adhesive inflammation, a cavity of some strength for the circulating blood is always kept entire, and no extravasation can take place, nor can the parts readily give way. Thus also, when in palpitations of the heart repeated pressure is made upon the ribs, they likewise are absorbed. We must suppose not only excessive but mistaken action of the absorbents, when, from external inflammation in the eye, they take up both the crystalline and the vitreous humors, leaving only a bag of water. When this happens to cataracts produced by contusion, and therefore by inflammation, we must attribute it, not to morbid action, but to the well directed efforts of nature to relieve herself.

One species of morbid action in the absorbents is not easily reconciled with the general laws of the animal economy, but the effect is too readily discovered, which is when they convey poisons into the system, such as the variolous, syphilitic, cancerous, canine, and others. Nor can we understand for what reason they translate matter from cancers and scrophulous tumors to distant, and sometimes to more noble parts, than those which suffer. This however, like many spasmodic affections, seems to be merely an effort of impatience, whilst the ordinary efforts appear to follow the most calm deliberation, and to be directed always by the best intention.

With regard to the general indications of cure in morbid action of the absorbents.—These must be derived from a consideration of the causes which produce morbid action, whether it be deficient or excessive.

In cases of defective action of the absorbents, the first attention must be paid to diet, which should be mild, yet generous, consisting of such articles as are most easy of digestion, with a moderate quantity of spice and wine. Further to assist the digestive powers of the stomach, and the general action of the absorbent system, recourse must be had to air and exercise. It is Boerhaave who has left us this direction:—Tum ut optimè digeri queant, condimentis, potu vinoso, exercitio, aëre, procurandum, § 1176.

By experience, all medical practitioners have been convinced that health and vigor depend upon the air we breathe: but no one, till Dr. Beddoes wrote upon the subject, was ever able to explain what the air contributed towards heat and life. They had observed that the blood acquires a florid color by passing through the lungs, precisely as when venal blood is exposed to the open air. They had remarked that the blood of those people was most florid who used most exercise; and that even the blood of horses after a long journey was more florid than when they had been confined without exercise in stables. They saw clearly that the blood of a cachectic woman is watery and of an obscure red; but that by increasing the blood's motion with friction, exercise, and medicine, it recovers its bright color This change they attributed to its passage through the lungs, where, according to Galen and the ancients, it received some spirit from the air imparting vital energy to the arterial blood. Boerhaave, from whose Institutes these quotations are taken, also asserts that the lungs receive something from the air, the nature of which he confesses himself unable to discover; but, in order to account for the red blood of fish, and the redness of the punctum saliens in an egg, he observes, that the gills of fish supply the office of lungs, and that air penetrates the egg to support the life and growth of the included chick, § 200—202.

Baron Van Swieten, in his Comment on the Aphorism of his master, Boerhaave, wherein air is recommended, has remarked, that prisoners excluded from the air, and patients long confined to hospitals, become cachectic; that in such situations it is very difficult to cure them; and that hence we may understand, why atrophy attends affections of the lungs, even when little is discharged by spitting, or lost by sensible evacuations. § 1174, 1176.

Exercise increases respiration and promotes the oxygenation of the blood; and by this it gives vigor to the system, and excites the action of the absorbents. It is the circulation of the blood which distributes vital energy to every part; for in syncope, and even in death, when it is a consequence of suffocation, all the vital organs remain perfect and entire; but for want of distribution of vital energy, by the circulation of blood, neither the heart, the lungs, the stomach, nor the brain, can perform their office; there is neither secretion nor excretion, and all action, both vital and voluntary ceases.

In those cachectic diseases, in which the circulation of the blood is languid, in vain will you pour in nutriment, unless at the same time by air, by exercise, and proper medicines, you promote the circulation, and consequently the secretion with the vital energy of the absorbents. Muscular motion, by compressing the veins, sends the blood with increasing vigor to the heart, which strongly stimulates that organ; the respiration is much quickened, the blood becomes highly oxygenated in its passage through the lungs, and in its return excites the heart to more powerful exertion, by which the whole arterial system is distended. This stimulates the vessels to contract with vital energy; the action and eaction are great; the contractions strong; all is activity, all is vigor. Hence it is that if, of two brothers, one takes to a sedentary life, and the other is constantly engaged in hunting, shooting, fishing, or in the cultivation of the earth: this, with a ruddy countenance and rigid fibre, will enjoy high health; whilst the other pale, bloated, and relaxed, will be incessantly consulting his physician.

Of the different kinds of exercise none is to be preferred to riding, because it agitates every part of the machine, and most powerfully promotes the action both of the exhalants and absorb-

ents. Sydenham relates the case of a friend, who, by neglect of exercise, had brought himself into so deplorable a condition, that he was dying of a colliquative diarrhœa, which no medicines could relieve. This man, by the advice of his sagacious physician, mounted his horse, defied all weather, paid no attention to his diet, but rode at first short distances in proportion to his strength, and continuing this practice without interruption for many months, came at last to ride his twenty or thirty miles a day without fatigue, and was restored to perfect health and strength.

Dr. Stack was consulted by the relations of a young nobleman then dying of atrophy, as it was thought, in Paris, to whom he recommended the Bath waters. The young nobleman was driven to despair by this advice, because he could not walk across his room, and was confined chiefly to his bed. But the marchioness his mother, a lady distinguished for spirit and resolution, prevailed on him to rise, supported him in his carriage, revived him with cordials when he fainted, and, by short stages at first, in less than six weeks brought him to my friend at Bath in perfect health.

In a very ancient history of Cornwall mention is made of M. Atwel, a clerical physician, who infallibly cured all diseases; and so great was his celebrity, that patients travelled to him from every part of the island west of London, to know what quantity of apples and milk, (for, excepting manus Christi, and such like cordials, that was the only medicine he prescribed,) would be good for them. Few of these, if they came from a great distance, consulted him in vain; before they got home they were restored to health. *Carew's Survey of Cornwall*, p. 60.

Sydenham assures us, that he has frequently cured both tabes and phthisis by horse exercise and long journeys, when all medicines had been given in vain, and this not merely in the incipient stages, but when night sweats and diarrhœa, usually the concluding symptoms, had appeared. Morton expresses in most energetic language some sentiments respecting the benefits to be derived from air and exercise, and we may venture to affirm, that most kinds of cachexy may be cured by these alone, even without the aid of a physician.

Frictions, in some degree, answer the end of exercise, by diffusing vital heat and promoting the circulation of the blood. The benefit to be derived from hence is evident in horses, who never enjoy high health when confined to stables, unless they are well combed and brushed.

Bandages, by pressure, assist weak vessels and promote absorption. It is for this reason that Boerhaave recommends compression in diseases of the weak relaxed fibre, because when either fibres or vessels are distended beyond their tones, their vital action will be weakened till it is wholly lost. And John Hunter has admirably stated that the best exciting power is pressure, which, if urged beyond the point of ease, sets the absorbents of the part to work, for the purpose of removing either the substance pressing or the part which is pressed. These therefore, in some cases, may be usefully applied.

In cachectic patients, attention must be paid to the organs of digestion, which are usually deranged, and loaded either with indigested sordes, corrupted bile, or phlegm. If the stomach is affected, an emetic must be given; or, if the smaller intestines require to be cleansed, gentle cathartics will be required, which in most cases may be followed by tonics and astringents. This Boerhaave has enjoined.

Ut verò organa primarum coctionum itidem benè disponantur, leni digestivo, vomitivo, purgante roborante, prospiciendum, § 1177.

But, whilst emetics prepare the digestive organs for tonics and astringents, they in many cases serve another useful purpose, by promoting absorption in every part of the system. Cathartics have the same effect, and among these none is more powerful than mercury, whether externally or internally applied. Indeed every increased evacuation excites absorption from distant parts, but, independent of this effect, mercury stimulates the absorbents, and thereby excites their action. Diaphoretics and diuretics unequivocally act upon the absorbents.

But the most effectual stimulant in all cachectic cases, attended by diminished excitement, is steel. This was the favorite remedy of Sydenham, and Boerhaave, and it has continued to maintain its credit, in the hands of all the most successful practitioners, to the present day. To this Dr. Smith owed his celebrity; and, from the experience of thirty years, I can venture to assure the student, that in few cachectic cases will it ever fail to cure. Professor Van Swieten says, 'In practice I have met with innumerable cases in which cachexy has been cured by this remedy alone, joined with grateful aromatics, after mild evacuants had cleared the first passages from mucus, filth, and indigested food; and he particularly assures us, that by steel filings he never failed perfectly to cure cachectic virgins, provided they consented to take air and exercise, and to avoid warm liquids.'

Chalybeates have certainly a two-fold effect; for as the natural vehicle of oxygen, and the constituent principle of red blood, they strengthen the digestive organs, and they excite the absorbents. Indeed all the metallic oxides, excepting the mercurial, act in the same manner, only in a superlative, and, therefore, in a less manageable degree. For this reason iron has maintained its empire; and whilst we have one oxide, which, when conjoined with the inhalation of vital air, in these cases may be regarded as infallible, we need be less solicitous about the rest.

I cannot conclude this article without making mention of electricity, which, as a powerful stimulant, has not only reduced swellings from sprains, and promoted the speedy absorption of considerable glandular and scrofulous tumors, but is known to attenuate fluids, and to excite strong action in the animated fibre, by which, among other remarkable effects, it quickens vegetation, increases perspiration, and restores the menstrual flux.'

Had our author been writing at the present moment he would have added, to this recommendation of electricity, the Voltaic modification of it; for it will be seen throughout the whole

the long extract which we have made, that there is a readiness evinced on the part of the author to receive every modern suggestion as an improvement.

Had he lived too to hear of the late experiments of Magendie, he would gladly have availed himself of them in adding moderate and judicious depletion as one of the most powerful means we possess of exciting the absorbent action. The experiments of the physiologist we have just named have always appeared to us exceedingly important in reference to this particular, and we should be disposed to place the practice referred to at the head of stimuli to the absorbent faculty. The principle upon which it proves to be so, seems that of removing a load from the vessels, and thereby enabling them to act with more freedom. We may here then advert to some important experiments of Magendie in reference to this point. 'I endeavoured,' he tells us, 'to ascertain by experiment the influence upon absorption which should be exerted by a state of fulness in the sanguiferous vessels. Having injected into the veins of a dog a certain quantity of water at the temperature of 40° (105° of Fahrenheit), I introduced into the pleura a solution in alcohol of nux vomica, the absorption of which was proved by its speedy and powerful effects. The effects, however, were not so immediate as had been the case when the veins were not thus previously injected; and in repeating the experiment, with a still greater quantity of water in the veins, I found that the effects of the poison were in the same measure more tardy in showing themselves; at length having thrown in as much water as it was possible for the animal to receive while he continued alive, the poison which in ordinary circumstances would have operated in less than two minutes, had not affected at the end of half an hour.'

'The condition,' Magendie continues, 'of the blood-vessels in reference to their plenitude was shown by these experiments to possess a considerable influence upon their absorbing power. What then, it became interesting to ascertain, would be the effects of an opposite state of these vessels? This was likewise put to the test of experiment in the following manner: a dog having been largely bled, the same quantity of nux vomica solution was thrown in, as in the former experiments, and the poison manifested itself in little more than half a minute, while, under ordinary circumstances, it would have required two minutes to produce the effect.

The veins of another dog were opened, and a given quantity of blood having been withdrawn, it was replaced by an equal quantity of water; in this case the absorption of the poison took place about the ordinary time.'

By these experiments then it is clearly manifested that plenitude of vessels, beyond a due proportion, interferes with the absorbing agency, and hence blood-letting, properly regulated, proves itself to be a stimulus to the absorbents, and is thus applicable to several diseased states that demand ultimately stimulating and supporting remedies.

There are some other medicinals beside those mentioned by Townsend, which likewise seem especially to operate upon the absorbent faculty. Digitalis may be instanced as one of these; hence its utility in dropsical swellings; and hence it has been used in those mesenteric affections to which we have above alluded, as the radix and source of many disorders incident to children. See the two first genera in the present class Iodine too, which has lately been employed for the discussion or dispersion of glandular enlargements, particularly that enlargement of the thyroid gland called bronchocele, seems as far as its influence can be traced to expend its virtues mainly upon the absorbents. We must not, however, expect to be able to trace this exclusive agency upon one part of the frame through the action of any one power or any one medicinal, but at the same time it much assists the therapeia of medicine thus to observe the particular influence of some drugs, or some excitants upon one more than another portion of the system; and, while we should be careful not too hastily to generalise, we should avoid being merely empirically observant. The exciting passions, as well as those that are sedative and depressing, may be made to stimulate the absorbents as well as other parts of the frame. In this case the influence is probably an extension of that which is primarily communicated to the sentient part of the organisation; and it is more than probable that hope and confidence, as well as exercise, had to do with these cures to which Mr. Townsend alludes as resulting from the invigorating and exciting power of exercise; indeed, the medical practitioner should never act without the recollection of the astonishing influence which the mental faculties possess over the physical functions of the frame, and, in those instances where the manifestation of good has principally been made through the medium of the nervous system, it may be that a considerable portion of the therapeutic effect has actually been produced through the blood-vessels and absorbents.

We now, then, proceed to consider the order and genera which Dr. Cullen has introduced, in some cases with obvious impropriety, into the class cachexia.

413. Order 1. Wasting. Emaciation.

Tabes. Atrophy.—The former with hectic fever, as having more to do with the absorbent system; the latter being without hectic, and therefore, although the falling away in flesh and strength must necessarily in its course be considerable, connected with the absorbent power, yet the nervous or sentient system seems to be the part primarily and principally affected.

'When,' says a modern author, 'the falling away in flesh and strength is connected with a disordered condition of the nervous and muscular energy, those plans of treatment are required which give tone and vigor to these parts of the frame; such as the vegetable bitters, the various barks, and the metallic tonics. When the complaint is rather tabid than atrophic, and the lacteal system is especially implicated, medicinals are called for, which stimulate this portion of the system. For the tabes mesenterica of infants I have found nothing better, in the gene-

ral way, than the hydrargyrus cum cretâ of the Pharmacopœia, with very small doses of digitalis.

℞ Hydrarg. cum cretâ gr. ij.
Fiat pulvis omni nocte sumendus ex vehiculo crasso.

Take of quicksilver with chalk two grains. Make it into a powder. To be taken every night in something thick.

Tinct. digitalis ♏ ij. ter in die sumendæ gradatim augens quantitat. usque ad ♏ vj.

Let two minims of digitalis be given three times a day, gradually increasing the dose to six. This combination of medicinals seems to be deobstruent, and excitative of the lymphatic and lacteal vessels; and in more advanced life, when nutrition seems impeded in consequence of defective action in the mesenteric absorbents, stell will, in general, prove one of the best stimulants. It will, for the most part, I think, be found, that steel is rather applicable to the tabid state, and other tonics to atrophia.

414. Order 2. Swellings.—*Corpulency; pneumatic swelling; tympanitic, or drummy swelling; uterine inflation.* Physometra.—The same author from whom we have extracted the above, places these four genera together and upon them makes the following remarks:—Corpulency needs no description; its obvious remedy is to lessen the ingesta, and increase the absorbent energy, which is best done by exercise. Emphysematic, or windy, swelling, is occasioned by a collection of air in the cellular membrane: it is attended, as the definition states, with a crepitating or creaking noise, and occasionally spreads over the greater part of the body. It is sometimes produced by wounds in the lungs, sometimes arises spontaneously, or without any manifest cause, and occasionally occurs in an inexplicable manner, from certain kinds of food that prove poisonous. When the collection of air is excessive, so as to prove troublesome, and happens in the thorax so as to impede breathing, scarifications of the cellular membrane will be found necessary. In all cases the occasional cause is of course to be sought for, and if possible subdued.

Of the drum-belly, as it is called, there are two species; the one abdominal, occasioned by a collection of air in the peritonæal cavity; the other intestinal, formed by air in the cavity of the intestines. In the former the swelling is more diffused and equal than in the latter, and there is not that emission of flatus which attends the tympanites. The continuance of either tends to dropsical effusion; indeed tympanites and ascites are not unfrequently combined; and they seem occasionally to alternate with each other. At this time I am attending a patient whose abdomen on one day or week seems distended with flatus, on another there are complete indications of watery collection.

Causes.—Debility in the absorbent or exhalant systems; intemperance, or low living; distending the stomach with tea, in place of taking more wholesome and substantial nutriment. Sometimes the suppression of ordinary evacuations will occasion tympanitic enlargement. Mental anxiety will produce it.

Diagnosis.—From dropsy, tympanites is distinguished by there being in the latter no fluctuation, while the former is without crepitus. There is not, necessarily, in mere tympanites œdematous swellings of the ancles, nor paucity of urine.

Prognosis.—Obstinate cases of abdominal tympanites often prove fatal. The intestinal is of a more fugacious and symptomatic kind, and is remediable by the removal of the causes upon which it has depended.

Treatment.—Expulsion of the wind in the first instance, and restoration of tone in the second, are the indications of treatment. Carminatives are required to fulfil the former, tonics are demanded to effect the latter.

℞ Spiritûs ætheris nitrici,
Spiritûs sulphurici,
Spiritûs ammoniæ aromaticæ, āā f. ʒß.
Aquæ menthæ piperitæ f. ℥iß.
Fiat haustus.

Take of spirit of nitric æther of sulphuric ether and of aromatic ammonia of each half a fluid drachm, peppermint water a fluid ounce and a half. Make them into a draught

℞ Decocti aloes compositi,
Infusi cascarillæ, āā f. ʒvj.
Fiat haustus.

Take of compound decoction of aloes and infusion of cascarilla of each six fluid drachms. Make them into a draught.

℞ Pulveris aloes compositi,
Pulveris cinnamomi compositi, āā gr. viij.
Olei carui ♏ ij.
Mucilaginis acaciæ q. s.
Fiant pilulæ iv.; bis terve in die sumendæ.

Take of compound powder of aloes and compound cinnamon powder of each eight grains, oil of caraway two minims, mucilage of acacia enough to make four pills. To be taken two or three times a day.

Warm plasters, as the cumin and compound galbanum plaster, may be laid on the abdomen with advantage; the abdomen, too, may be bandaged; if the species be abdominal, and not intestinal, puncturing may be had recourse to.

In order to restore tone, the barks, especially cascarilla, are indicated, or other tonics; while during their use, as well as during the employment of warm purgatives, all flatulent articles of diet must be carefully abstained from, more especially the legumina—beans and peas.

Uterine inflation we cannot suppose to take place to any extent, unless there be some vaginal obstruction to the passage of the air. It seems, however, to be an admitted fact, that air does occasionally collect in the womb, and discharge itself from the vagina in considerable quantities and considerably to the annoyance of the patient.

413. *Dropsies.*—In the proem to the present article will be found some intimations principally extracted from a modern writer on the general pathology of dropsical affection; it will be observed that the principle of referring watery accumulation to any one cause was combated and it was moreover intimated that pathologist

of the modern school, in their eagerness to oppose the old assumption of dropsy being attributable to debility, had in some instances too largely and gratuitously inferred the necessity of inflammatory action previous to the throwing out of the serous collection constituting the disorder.

It was at the same time admitted that these inflammatory conditions are necessary to be recognised under several circumstances of dropsy; and upon the whole it was concluded that a mixture of the old and new admission of hydropic production is that which is likely to lead to a correct view of the subject.

We now proceed to illustrate these principles by considering the several affections which are comprised in the class; but we shall not pursue the same order which Dr. Cullen has adopted in the arrangement of the genera, for we consider the more natural arrangement to be that of dropsy of the abdomen (ascites), of the chest (hydrothorax), of the womb (hydrometra), and of the head (hydrocephalus). Hydrorachites or spinal dropsy, and hydrocele or dropsy of the scrotum, will be treated of in the article SURGERY.

414. *Dropsy of the abdomen.* Ascites.—It will be recollected that, when treating of inflammation generally, we adverted to two distinct kinds of this disordered action, viz. the phlegmonous and the erysipelatous, the one being circumscribed and deep seated, and more especially tending to suppuration; the other being spreading, and membranous, and disposed more particularly to effusion. Now there is one species of dropsy which has its origin in this erythematic kind of inflammation; and it is absolutely necessary in every case of dropsical effusion to aim at investigating the prior circumstances both local and general, in order to ascertain how far the effusion has or has not been occasioned by inflammatory action. Let us further notice the especial characteristics of that which we may term inflammatory dropsy of the abdomen, a very frequent concomitant of diseased or obstructed liver. What are the vascular conditions of the abdomen occasioned by such obstructions to the free circulation of blood through the liver? It is sufficiently easy to conceive that the blood-vessels which terminate in the vena portæ must necessarily, in consequence of this vessel becoming obstructed either in its trunk or its branches, be more disposed to plenitude than is consistent with their natural condition; that such plenitude will extend itself to contiguous vessels; that thereby congestions will be induced; and, should the body at the time be exposed even to slight causes of inflammation, such inflammation will come to be readily established; that this will assume a chronic, and perhaps indolent kind of character; that where cellular kind of substance exists it will take on an erythematic aspect; and, where other kind of membranous texture is the seat of the inflammation, the disposition will rather be to the effusion of coagulating lymph; that thus effusions and adhesions will either separately or conjunctively be established, and dropsy will be formed either with or without adhesive unions of membranous structure. But even this kind of inflammatory dropsy may at times take place in the abdomen without the preliminary condition of diseased or obstructed liver. Let it, however, be recollected, that obstruction to free circulation through other viscera may be attended with the same effect. That any circumstance which interferes with the due transmission of blood through the substance of the spleen may be the occasion of hæmorrhage has already been remarked; and it may now further be stated, that the same circumstances of this viscus, which in one subject or at one particular time of life predisposes to hæmorrhage, may, under different circumstances, and at different ages, have a tendency to induce congestion, inflammation, effusion; and thus to form dropsy. But further, even obstructions to the free circulation through the heart may, under certain tendencies in the body, conduce to the same event. Hence we see affections of the heart and of the lungs, not only terminating at times in dropsy of the chest, but in general dropsy, and dropsy of the abdomen, in which case, as indeed in all others of congestion, inflammation, and effusion, we have two causes operating: there is the vascular fulness consequent upon the blood being as it were thrown back upon the vessels by not having a free transmission through the chambers of the heart, and there is the tendency to effusion arising out of the very debility that was the first cause of the obstruction supposed. When then there is in the age, or the constitution, or both, a bias towards dropsical accumulations, we see how readily this is converted into the actual state by any obstruction occurring in the more important viscera, and the most common media through which this kind of dropsy is engendered are the liver, the spleen, the heart, and the lungs. Let then the practitioner, when he is called to judge of the nature and to determine on the treatment of dropsy, always pay great attention to the condition of these respective viscera, and to the presence or absence of general inflammatory irritations. But what is the essence of that species of dropsy which may be designated by the title of serous? Dropsy, let us recollect, is a preternatural increase of serous exhalation. The immediate cause of it then must in all instances be a loss of balance between the exhalants and absorbents; now this want of healthy correspondence, so to express ourselves, between these two orders of vessels, may be either positive or relative, that is, the absorbents may continue their due activity, and take up their usual measure of effused fluid; they may even do more than common; and yet, from the excessive exhalations, that more may not be equal to existing circumstances, and dropsical accumulations will take place by virtue of increased activity in the exhalants, which is the case in the inflammatory dropsy that we have just been conceiving. On the other hand, this effusion may not be more than natural or healthy, and yet, inasmuch as the absorbents have lost somewhat of their wonted tone and action, the same accumulation will take place, although in a different manner, as in the former instance. But here, of course, both the systematic and local disturbance will assume a different aspect; there will in this last case be more of torpor, and less of irritation, more of

paleness and weakness, and cachexy as it is termed, and less of tendency to partial accumulations, to irregularities in the circulation, and to high colored excretions. A late most ingenious author on the subject of dropsy has made the division into two kinds to hinge principally upon the circumstance whether the urine is loaded or not with serum; and, consequently, whether it does or does not evince a tendency to coagulate. We believe, however, that the distinction will generally be traceable with more accuracy by recognising other symptoms in combination with that of the urine, as marking the prevalence either of inflammatory action or lymphatic torpor; and establishing our principles of treatment upon this recognition. Besides the question, Is dropsy inflammatory or lymphatic? there is another point of moment to ascertain in regard to the rationale and management of all dropsical affections, viz. Is it organic, or is it general? In other words, does the effusion which forms the dropsical enlargement depend upon some local condition merely, of the part or viscus in which it is found, or is the local swelling an accidental and particular expression of general affection? On the diagnostic marks between encysted and other dropsies we shall soon say something further; it may here, however, be generally stated, that when the dropsical effusion is merely local, it most usually depends upon some accidental source of disturbance in the vessels of the affected viscus which may take place without any constitutional disposition to serous debility; but that when the swelling is of a more diffused and general kind we shall usually find, whatever may have been the exciting causes, that the actual disorder has been induced through the medium of that kind of habit which we may designate lymphatic, which if not actually the scrofulous temperament is at least nearly allied to it. Having made these preliminary remarks, on the rationale of dropsical production, we shall now proceed to treat more especially of ascites or dropsy of the abdomen.

Symptoms.—The existence of this complaint is for the most part unequivocally marked by protuberance on the belly, attended with fluctuation, perceived by placing the hand on one side of the abdomen, and gently striking on the opposite side. Dropsy of the abdomen may, however, exist, without any perceptible fluctuation.

Ascites is attended for the most part with scarcity of urine, with thirst, and some degree of fever, which usually, especially when it is of the lymphatic kind, partakes more or less of a hectic cast. Now it will readily be understood of what consequence it must be to ascertain the precise nature, both systematic and local, of the complaint, before we can set about forming any rational indications with regard to its treatment, or any correct opinions on the probability of its duration and event. Whether is it inflammatory? and if so, is the liver (the most usual source) or any other part or viscus the seat of the inflammation upon which it has depended? or is it lymphatic? In other words, does it originate in an undue torpor of the abdominal absorbents? Is it organic, merely? that is, does it arise out of the state of the organs concerned with primary reference to the condition of the whole body? or is it rather a mere local expression of general lymphatic weakness? If the first be the case, that is, if the complaint be inflammatory, we shall find more or less of tenderness upon placing our hands either upon the region of the liver, or upon the surface of the abdomen. We shall find the urinary excretion high colored rather than serous, and the fever will at first be rather of the usual pyrexial type, and only in the course of the malady will it come to put on a more decidedly hectic charater. If too, as is for the most part the case, the liver be the principal organ in fault, there will be present, more or less exquisitely marked, those characteristics which we have previously pointed out as belonging to liver affection, whether the disorder be inflammation, or schirrus, or mere congestion. If the dropsy be merely lymphatic, without any present or prior inflammation, it will for the most part be accompanied with œdematous swellings of an anasarcous kind in the legs and other parts, it will be without local pain or tenderness, and it will from the first have been signalised by a fever rather of the hectic than the common type. If the disorder be the result of some merely local inflammation, the inflammation of the part will have been of a decided kind, and often it will have depended upon some exterior or local cause. In each case the required treatment will vary, and saline, stimulant, or absorbent diuretics, will, according to circumstances, come to be employed with greater or less propriety and effect.

Prognosis.—The prognosis in dropsy of the abdomen will be always unfavorable if the disorder is accompanied by much indication of liver disorder, by marks of broken down stamina, and attended at the same time by the symptoms of slow inflammation going on in the peritonæal membrane.

Treatment.—What medicines, let us enquire, will it be proper to employ in case of inflammatory or congestive dropsy? Bleeding is recommended by some practitioners to a considerable extent, seeing that the effusion is brought about by the local plethora, and to lessen such plethora is thus to strike at the root of the disease. For the most part, however, we should be disposed to institute bleeding upon different premises, and consider it indirectly stimulant to the absorbent energies, upon the principle we have recently referred to as established by the experiments of Majendie.

Although we would by no means say that there may not be instances of inflammatory dropsy, in which a large use of the lancet may prove beneficial, we think it of moment to caution the unwary, in reference to bleeding, of the high probability of doing irreparable mischief by making too free with the loss of blood. It is in this kind of dropsy especially that the saline purgatives are of so much efficacy; and the supertartrite of potass, or crystals of tartar, hold justly a high consideration in dropsy of the belly accompanied by marks of lurking inflammation. In doses of a drachm, three or four times a day, this medicine will often act kindly upon the kidneys, and prove at once aperient, anti-inflammatory, and diuretic. The acetate of potass too, in doses of about

scruple or half a drachm, is a saline deobstruent in these cases of considerable efficacy; and even the subcarbonate of potass alone, especially when aided by much dilution, is a medicine of no mean virtue when employed with a view to its diuretic and antihydropic qualities. Its dose is about fifteen grains.

With respect to purgatives of a more drastic nature, which are recommended and used in ascitic cases, there ought to be some caution used lest we induce or rather increase the inflammatory disposition.

PURGATIVES.

℞ Pulv. Jalapæ ʒß.
Zingiberis ℈ß
Ol. juniperi ♏j.
Fiat pulvis: semel bisve in die sumend.

Take of powder of jalap half a drachm, of ginger half a scruple, oil of juniper one minim. Make them into a powder to be taken once or twice a day.

℞ Pil. hydrarg. ʒj.
Pulv. scillæ ʒß.
Extract. colocynth. ℈iiß.
Ol. juniper ♏xij.
Syrup q. s.
Fiat massa; in pilulas xxx divid., sumat ij ter ꝑ die.

Take of blue pill one drachm, powder of squill half a drachm, compound colocynth extract two scruples and a half, oil of juniper twelve minims, syrup enough to make into a mass, which divide into thirty pills, two to be taken three times a day.

There is one medicine which seems to operate almost with specific virtue in abdominal dropsy, and that is the elaterium (wild cucumber). While, therefore, we should be cautious in the administration of gamboge, or of scammony, in dropsies accompanied with hepatic inflammation, we should never hesitate in the employment of the elaterium, one grain of the extract of which, or in some cases only half a grain, acts often almost with the efficacy of a charm, and does not seem to be followed by so much debility as we might à priori be led to suspect. This medicine indeed seems to be applicable to either species of dropsical affection; and proves salutary, whether the serous effusions have depended upon mere lymphatic torpor, or have been brought about by chronic inflammation. It is to the lymphatic species of dropsy that the digitalis seems more especially applicable: and this fact, to which Dr. Blackhall alludes, would seem to establish the principle to which we have formerly adverted, respecting the stimulating quality of this medicine, when used so as to gradually act upon the absorbent system of vessels. Upon the whole, however, we are inclined to think that, where we require active measures in the way of procuring large and sudden evacuations, the foxglove must be thought of with considerable reserve, and it is certainly much more objectionable in the general way than the elaterium.

Among the more stimulant diuretics, applicable especially to the lymphatic species of dropsy, we may mention the lytta (cantharis). This substance requires of course attention to its progressive and peculiar effects; since improperly employed, or in too large doses, it is apt to prove the very contrary to a diuretic, and has been known actually to excite an inflammation in the kidneys. We have generally, for the purpose of preventing these probable consequences of the misuse of cantharides, been in the practice of combining with it another diuretic of a different class, but which can scarcely ever be objectionable, viz. the spiritus ætheris nitrici; about fifteen minims of the tincture of one, and thirty or forty of the other, with two or three drachms of mucilage of acacia, form a good and beneficial composition in many cases where we wish for the operation of a stimulant diuretic. Squill is another medicine of much reputed efficacy in dropsy; but perhaps more applicable to dropsy of the chest than of the abdomen. On oil of turpentine much praise has been bestowed by some practitioners, and tobacco has been also extolled. The meadow-saffron also, the colchicum autumnale, has been much praised both in dropsical and some other affections. The copaiba too is possessed of diuretic qualities and may be applicable to dropsy. Mercury also is a powerful remedy for dropsy, but we think with Dr. Blackhall it has been too often not only indiscriminately but mischievously used: such indeed is the power of this medicine upon the lymphatic and absorbent system, that it is not uncommon to see persons fall into a dropsical state after the liberal use of mercury, which may indeed partly depend upon the tendency this medicine has to excite internal erythematic inflammation, but is more especially attributable to the debility engendered in the lymphatic vessels by their being from mercury's protracted use kept in a condition of inordinate excitement.

Stimulant, saline, and absorbent diuretics, are the three divisions which may be made of these medicinals. And there certainly seems a foundation, in fact, for such division. Thus we have squill, we have lytta, we have turpentine, which appear to increase the flow of urine, either by a sort of direct or specific action upon the kidneys themselves, or by exciting such an action on the stomach, and such influence being propagated by the nerves to the kidneys. Saline diuretics, such as crystals of tartar, acetate of potass, carbonate of potass or soda, nitrate of potass, or nitre, are on the other hand supposed to be received into the circulation, and, passing off with the urine, to stimulate the vessels of the kidneys, and increase the quantity secreted. This mode of operation does not appear, however, quite satisfactory to the mind; and it certainly is not confined to the saline class of diuretics, since the copaiba and the turpentine, among the stimulant order of these medicinals, appear to be taken up into the circulation, and to pass off by the kidneys in this somewhat inscrutable manner. 'There is still perhaps another mode,' says a writer on the materia medica, 'in which certain substances produce a diuretic effect, and that is, by promoting absorption. When a large quantity of watery fluid is introduced into the circulating mass, it stimulates the secretory vessels of the kidneys, and is carried off by the urine. If therefore,' continues this writer, 'absorption be

promoted, and if a portion of serous fluid, perhaps previously effused, be taken up, the quantity of fluid secreted by the kidneys will be increased. In this way digitalis seems to act; its diuretic effect is said to be greater when exhibited in dropsy than it is in health.—Murray. Now it will be found useful to familiarise our minds with these various modes of operation in diuretic medicinals, since, as we have above seen, both their efficacy as diuretics, and their propriety of exhibition, are materially dependent upon the precise condition of the frame in which they are employed. We shall not again go over the ground of these distinctions and respective requirements, but shall content ourselves with saying, that in the lytta we have an example of the stimulant; in the acetate of potass of the saline; and, in digitalis, of the absorbent order of diuretics.

Before we quit the subject of the treatment which is requisite to disperse dropsical accumulation, it may be right to mention that the practice of tapping in abdominal dropsy is one which, both in reference to the time at which it is done, and the circumstances under which it is proper to do it, demands some discrimination: if performed very early, it may have proved an unnecessary interference; and, if deferred very late, it may not only add to the prevailing irritation, but be likely to produce an inflammatory affection of the peritonæum, which the patient, in his weak condition, will not be able to encounter. Although often of considerable temporary service, tapping can never be looked upon as a radical remedy; and, when we are convinced of much and extensive disorganisation of the liver, it is better for the most part to decline it. Puncturing or scarifying the thighs, when anasarca accompanies ascites, will often diminish even the abdominal tumor; and this last practice need never be objected to; but the application of blisters, to produce the effect of drain, may, in the weakened and irritable state of the body, give rise to sloughing sores.

Another important indication in dropsical affections remains to be spoken of, namely, how the re-accumulation is to be obviated. It is evident enough that such kind of diet should be selected for the individual as would prove nourishing without increasing irritation; and, when there is not any objectionable degree of irritation present, tonics are certainly called for; indeed, we are inclined to think that our vascular and inflammatory notions in reference to this, as well as to other diseases, forbid, to rather too great an extent, the exhibition of supporting powers, lest we should augment the inflammatory disposition. Let it be recollected how serviceable Peruvian bark often proves in erythematic inflammation, as in St. Anthony's Fire, occurring in certain conditions of the system; and let the analogy be acted upon with caution in reference to dropsical inflammation. The following observations on the bark and steel we extract from Dr. Blackhall. 'Perhaps practitioners,' says Dr. B., 'are too much in the habit of considering bark and steel as equivalent where tone is wanting. In the present disorder it is far otherwise, bark being to be preferred after dropsy of young persons, of acute disease, and of sound stamina; steel being suited to a vitiated rather than to a feeble habit, and indicated more by a pale sallow complexion, and want of red color in the blood.'

415. *Dropsy of the chest.* Hydrothorax.

Symptoms.—Difficulty of breathing, especially in a horizontal position, or upon more than common exercise; sudden startings from sleep; paleness of face, with occasional flushes of a hectic kind; starting out of sleep, with palpitation and oppressed breathing; numbness of the arms, or occasional pains in them; diminished urine and thirst; irregularities of pulse, and œdematous ancles.

The symptoms indeed vary according to the part of the chest implicated in the disorder; the effusion constituting the dropsy is sometimes confined to the pericardium, and in that case the patient is not so much inconvenienced by a horizontal position. Sometimes the subject of hydrothorax finds the impediment in breathing come upon him immediately upon lying down, at other times the dyspnœa is more gradual in its induction; and in this last case we may suppose the water to be rather in the substance of the lungs than in the cavity of the pleura, as the communication of the effused fluid is not so readily made from one to another portion of the cellular structure. When palpitation of the heart is a prominent symptom, we are generally disposed to infer that the effusion is principally into the pericardium. These irregularities of the heart occur, however, in consequence of the general obstruction to respiration and circulation that effusion into any portion of the chest supposes; and it is not easy to fix upon any one pathognomic symptom as indicative of one or another portion of the thoracic system being disordered.

Causes.—Hydrothorax, like ascites, may be the result of obstruction, or lymphatic debility, or membranous inflammation. It is very often symptomatic of other disorders, and not uncommonly connects itself with ascites. Its exciting causes are those which produce dropsy generally. Long continued asthma gives a tendency to, and often terminates in, hydrothoracic effusion.

Diagnosis.—The accompanying dropsical indications, such as œdema of the ancles, and paucity of urine, and thirst, generally distinguish hydrothorax from mere dyspnœa; than these last two hydrothorax is in the general way more permanent and less intermitting. The fluctuation externally, of which systematic authors speak, can very seldom be detected, even when the fluid is in the thoracic cavity. When fluctuation is perceptible it is generally matter or pus which causes it, and this the result of active inflammation on the chest.

Prognosis.—When much organic disease, or any change of structure, has induced the ailment, the prognosis is for the most part unfavorable; and it is seldom that the malady is permanently overcome when it may have resulted from chronic and insidious inflammation. We ought always to be guarded in our prognosis, even when we suspect fluid in any part of the thoracic cavity; for it is very often that the patient under these circumstances dies suddenly: a mere turn of the body will occasionally extinguish life.

Treatment.—Squill and foxglove seem more especially adapted for water in the chest, as elaterium seems applicable to abdominal dropsy, and with these small quantities of mercury are to be added should there be any attendant symptoms denoting hepatic affection.

℞ Pulv. digitalis purp.
Pulv. scillæ, āā gr. xv.
Pil. hydrarg. ℈j.
Camphoræ ℈ij.
Ol. juniperi ♏ viii.
Syrupi q. s.
Fiat massa; in pilulas xxx. dividenda. Sumat ij ter in die.

Take of powder of foxglove and squill of each fifteen grains, blue pill a scruple, camphor two scruples, oil of juniper eight minims, simple syrup enough to form a mass, which divide into thirty pills. Two to be taken three times a day.

℞ Tinct. cantharid. ♏ xij.
Sp. ætheris nitrici ʒj.
Mucilag. acaciæ ʒiij.
Mistura camphoræ ℥iss.
Fiat haustus; ter in die sumendus.

Take of tincture of cantharides twelve minims, nitric spirit of ether a fluid drachm, mucilage of acacia three fluid drachms, camphor mixture a fluid ounce and a half. Mix for a draught. To be taken three times a day.

℞ Myrrhæ ℈ss.
Ol. juniperi ♏ ij.
Pulv. rhei gr. vj.
Syrup. simp. q. s.
Fiat bolus; ter in die sumendus.

Take of myrrh ten grains, oil of juniper two minims, powder of rhubarb six grains, simple syrup enough to make into a bolus. To be taken three times a day.

℞ Tinct. colchici f. ℥ss
Syrupi aurantii f. ℥ss.
Fiat syrupus cujus; sumat æger cochleare minimum subinde, donec nauseam promoveat.

Take of tincture of meadow saffron a fluid half ounce, syrup of orange peel a fluid ounce and a half. Make them into a syrup; of which let the patient take a tea spoonful frequently, until nausea be produced.

416. *Water in the head.* Hydrocephalus.—Dr. Cullen is remarkably defective in his pathological account and systematic arrangements of encephalic affections. The water in the head, to which he alludes in this part of the nosology, is that congenital kind which some authors have described as the external, to distinguish it from that which is the result of a morbid action, which occurs after birth, and where the effusion by which the malady is constituted, or rather by which it is terminated (for the actual disease often exists long prior to the effusion) is principally found in the ventricles of the brain.

The only notice which he takes of this last affection is under the head of apoplexy; where the student, by turning to the nosology, will find the hydrocephalic apoplexy marked as one of the genera, and defined, apoplexy coming on by degrees, attacking children, and individuals under the age of puberty, attended by febricula, and pain in the head, which is succeeded by a pulse slower than natural, a dilated pupil of the eye, and drowsiness.

The fact is that there are several ways in which effusion is effected upon the substance or in the ventricles of the brain, one of which constitutes the hydrocephalus of the present genus; which, as we have above remarked, is a congenital disorder; the process of ossification does not go on as in other children, but the head, large at birth, continues to increase; the faculties, instead of gradually developing themselves as in other children, are irregular in their manifestation; and, sometimes, with a generally idiotic condition of intellect, the patient will manifest some one particular faculty or sentiment, even in a more than ordinary measure. We recollect one remarkable instance of this kind of hydrocephalus, in which the ear for music was extraordinarily nice and delicate. While the head enlarges the limbs continue small and powerless; and should the child survive it is obliged to be carried about, often even at an advanced age, from want of power and growth of limb.

Sometimes this disorder becomes spontaneously cured; at other times the head continues of an enormous size; but the bony process after a time becomes complete, and the patient lives for some years with a diminutive stature and defective intellect; for the most part, however, it terminates fatally. When it only exists to a certain extent it has seemed to us occasionally to yield to medicinal treatment given with a view to act upon the absorbent system. And, even on the day that we are writing these remarks, we have seen the parent of a child who was the subject of this disorder, and whose life was not expected by the parents, but who is now a strong and lively child. Dr. Good mentions the case of an hydrocephalic subject of this kind having a grain of calomel given to it for a length of time every day; and he states that the individual is now a student at one of the English universities. Our own plan of treatment is that of administering very small doses, gradually repeated, of tincture of digitalis combined with the hydrarg. cum cretâ, as mentioned under the head of *Tabes*. Lately the water has been discharged by a puncture at one of the sutures, in more decided cases of hydrocephalus externus, and a bandage applied so as to promote absorption and prevent re-accumulation. But in most instances, to say the least, the effusion has returned in spite of all precautions to obviate it.

There is a second kind of hydrocephalus which is only congenital in its tendency; that is, an infant is born with a decidedly strumous constitution; it is perhaps injudiciously fed and nursed; the mesenteric system of vessels become disordered; irregular chylification is the result. From this irregularity in the supply of nutritious matter, together with the inordinate stimulus to which the infant is subjected, the brain becomes inordinately excited, now being too much and now too little stimulated; slow insidious alterations in consequence occur; the gradual and orderly process of development is interfered with, and hydrocephalus steals upon the child

insensibly. This kind of disorder too is remarkably under the influence of deobstruent mercurials and small doses of foxglove, as alluded to just now under the head of external hydrocephalus.

There is what is called the water-stroke, in which the effusion is made as if by a sudden rush, and which seems to be the result of the exhalants all at once giving way, for want of power to perform their functions properly. In this case the marks of effusion, such as squinting and paralysis and convulsions, come upon the child at times almost instantaneously; and this species of hydrocephalus very frequently is metastatic, that is, some other disorder has existed perhaps for some length of time, it suddenly yields, and in its place this brain affection is thus induced.

For the most part this kind of hydrocephalus is out of the reach of remedy; if any thing may be expected from medicine, it is from those substances which should excite a large discharge from the emunctories, more especially from the kidneys, and thus cure the complaint by a sort of artificial metastasis; but we repeat that very little is to be looked for under these circumstances, of perhaps broken-down frame by a previous disease, and a large effusion into the ventricles of the brain. Occasionally we shall find, however, that symptoms of oppressed brain, as if from the source now supposed, will suddenly be induced, and examinations after death will not justify our previous conceptions of the disorder's precise nature. The last case we witnessed of this kind, of seeming water-stroke, was in the child of a physician, who appeared to be recovering from a violent attack of inflammation of the chest, connected with the virus of hooping-cough: this promised amendment was suddenly and unexpectedly succeeded by marks of compressed brain, as if from effusion, but upon post mortem inspection very little cerebral lesion of any kind was discoverable.

These different kinds of hydrocephalus are all for the most part indices of scrofulous habits; but there is a fourth species, which is not confined so much as in the other cases to one particular kind of constitution. It is still however of more ready occurrence in such as have a tendency to lymphatic debility. Although most frequent in children under twelve years of age, it is sometimes observed in adults. It has been divided by Dr. Whytt, and others who have followed him, into three distinct stages; the first of which is invariably characterised by a pulse of increased quickness and comparative strength; in the second the pulsations become slower and more feeble; in the third and last stages the rapidity is increased beyond even that of the primary stage; but this increased action is now attended with extreme debility. These different changes in the circulation are not however always to be traced even in the acute or phrenitic species of hydrocephalus, in that order and undeviating regularity which the observations of Dr. Whytt would lead the young practitioner to imagine, although it is a disorder of much greater regularity than the other. Obscure affections of the stomach, and a general feeling of febrile lassitude, are often the precursors of the first or inflammatory stage of acute hydrocephalus. At other times feverish heat, intolerance of light, violent pains in the head, and vomiting, are the earliest signs of the disorder, to which the attention of friends is called. These symptoms, Dr. Rush tells us, are frequently attended with a remarkable impatience of sound; and, although we have not much observed this, it is easy enough to conceive, when the seat of the inflammation is about that part of the brain more particularly which is connected with the auditory nerves. The pain of the head is often confined to one side; and, in proportion to its intensity, the nausea and vomiting become less urgent, while, with the remission of the pain, these symptoms are disposed to recur. Respiration is sometimes at this period of the complaint spasmodic and irregular, the bowels are often so costive as to require strong doses of purgatives, in order to procure evacuations; at other times a diarrhœa is present. This stage sometimes lasts for several days; it is then succeeded by the second, which commences by a sudden reduction of the pulse, and other symptoms of irritation. The pain of the head now becomes less acute, and in some measure changes, not merely its degree, but its kind; torpor and insensibility to light succeed to watchfulness and visual irritation; the child now lifts his hands to his head (this symptom indeed is often present in the first stage, though not so observable); he now frequently utters piercing screams; strabismus, or squinting, in a degree takes place; an invincible inclination is shown to a horizontal posture, and to having the head particularly low; and there is a motion of the head from side to side, and a desire to throw the head back when the child is lifted up, which are both remarkably characteristic of effusion upon the brain; the bowels still continue torpid; and after these symptoms have continued for some days, perhaps a week, more or less, the complaint very often seems to be on the decline; deceitful semblances of returning health are noticed, so much so indeed, that parents, and even practitioners, are sometimes induced to think that either nature or medicine has begun to operate a beneficial change. There is less irritation, less fever, the beats of the pulse become more regular, and the child evinces a disposition to rouse himself, and notice sur rounding objects. This semblance, however, o amendment is but a prelude to the final perio of the disorder. It commonly lasts one or tw days, and then the pulse, suddenly almost, be comes again very rapid, so much so indeed, tha it is often not to be counted. Dr. Whytt tel us that he has been able to number 210 pu sations in the space of a minute; this extrao dinary rapidity does not however, as in t quickness of the first stage, last through t whole of the day: it comes on and declines wi the accessions and remissions of the hectic flu in the cheek. The eyes at length become inse sible to the strongest light; convulsions sup vene, and life is terminated. The duration this last period like that of the others is irre lar. Sometimes the patient is carried off

a few days from its commencement; at other times the child lingers in a hectic and convulsed state for some weeks; and Dr. Monro has informed us, that the last stage has been known to be protracted even to the fourth month. In the general way, however, the whole period of the malady, from its commencement with inflammatory irritation to its termination in hectic, convulsions, and death, is less than a month. The lymph which is thrown out upon the brain is found for the most part to be coagulable, proving the disorder to have been in the first instance inflammatory.

Distinctions.—As the hydrocephalus is very frequently present when not suspected, as it is often on the other hand suspected when not present, and as it is always of much moment to distinguish as early and as precisely as possible between this and other affections with which it has a deceitful resemblance, we shall here point out the leading features of difference between it and one or two other of childrens' disorders, but the possibility ought always to be recollected of one of these complaints running into the other, and that they exist often conjunctively. Worms, difficult dentition, tabes mesenterica, and that kind of irritation which has been denominated infantile remittent fever, are the particular affections that have sometimes been suspected, and at other times commuted for true hydrocephalus internus.

When the state which we apprehend to be hydrocephalic, arises from worms, there has for the most part during the whole of the indisposition been more of a dull heavy pain in the head than that acute sensation which often characterises the first stages of hydrocephalus. In worm cases there is never found that irritability to the light which likewise in a great number of instances marks the first stage of hydrocephalic irritation. On the contrary, the pupil of the eye, from first to last, is large and inirritable when the disorder is occasioned by worms. It is not uncommon too for the pain in hydrocephalus to be distinctly seated on one or the other temple, while the pain occasioned by the presence of worms is indistinct and hardly referrible to one more than to another part of the head. As a characteristic of worms, we frequently find a tumid thickness in the upper lip, or the whole space between the nostrils and the margin of the lip; there is too almost invariably an irritation in the membrane of the nostrils, which inclines the little patient to be constantly picking or rubbing the nose. This species of irritation is by no means common to the hydrocephalic state. When worms are present the appetite is for the most part extremely irregular; now voracious and hardly to be satisfied, and now more than commonly delicate; but in the hydrocephalus, in the early stages, and even during the whole of the complaint, there is for the most part an indifference about taking food. In instances of worms there is often a tumefaction about the abdomen, as well as in the upper lip—this is not usual in hydrocephalus. Further, worms often occasion the stridor dentium, as it is termed—grating of the teeth in sleep, and even convulsive or epileptic fits, neither of which affections is observed in dropsy of the brain, excepting in its final stages. Lastly, in cases of worms, there never is any thing of that order and succession of symptoms, which we have pointed out above, as not unfrequently seen in hydrocephalus; first, of irritation; secondly of a sort of exhaustion, or apoplectic oppression; and, thirdly, of a still greater irritation as preliminary to death.

Difficult dentition not only often gives rise to symptoms very similar to hydrocephalus, but very frequently actually produces it—the inflammatory irritation which it excites extending itself from the gums to the brain. When, however, the state is merely that of teething irritation, the gums and mouth are for the most part hot and inflamed; the bowels, though irregular, are more easily acted on than when the brain is actually affected, and that symptom of extreme susceptibility to light in the first instance, and subsequently of torpor, or of squinting, is not attendant merely upon teething. From tabes mesenterica, hydrocephalus is to be distinguished by the absence in the latter of that tumefaction and knottiness in the abdomen which is, as we have before stated, the grand characteristic feature of the former. In tabes mesenterica, too, the attendant fever is from the first rather of the hectic than of the common kind, while the first stage of hydrocephalus is very often marked more by ordinary febrile irritation. There is always too, and necessarily, a wasting of the flesh to a great degree, consequent upon the deprivation of nutriment to the blood, in the mesenteric atrophy; but the hydrocephalic patient will often go through the whole course of the complaint with comparatively little reduction of flesh or strength; since it is possible for the brain to be very extensively diseased, and the process of chylification nevertheless to proceed without much interruption. Lastly, that disordered state which has received by authors the denomination of bilious remittent, or infantile fever, very frequently assumes an appearance which gives rise to suspicion that all is not going on well in the head; and indeed this suspicion is not unlikely to be well-founded, for we would wish again and again to impress the possibility of one complaint falling by almost insensible gradations into the other. There are, however, certain diagnostic marks between the one and the other affection, and these have been so well detailed by Dr. Pemberton, in his work on the Diseases of the Abdominal Viscera, that we shall make use of his words in pointing them out:—'In hydrocephalus internus,' says Dr. P., 'there are occasional screamings in the sleep, with a continual tossing of the hands above the head, and an intolerance of light, with more or less of squinting; but I think I may say that, in the complaint before us (remittent fever), there is hardly ever what can be called screaming, and there is seldom intolerance of light, and never squinting; and moreover, though the hands are often carried to the face, it seems more from an inclination to pick the skin from the lips, eyes, and nose, than occasioned by the painful restlessness which attends hydrocephalus. In the delirium of hydrocephalus, the faculties are totally destroyed, and the muttering ravings of the patient are without sense or reason, and from this

state he cannot be roused. But in the other species of delirium the child, during this state, can at any time be recalled to his senses, which he will retain for a few minutes, acting and talking consistently. In remittent fever the appetite is destroyed; in hydrocephalus, on the contrary, the patient will take, without reluctance, whatever is offered, apparently making no distinction between what is palatable and what is nauseous. This difference of the appetite in the one and the other complaint is a most important feature of distinction between the two maladies.'

Dr. Pemberton would have done well to add, that the wasting of flesh is not so evident as in remittent fever. Upon this difference we have just observed in marking the diagnosis between tabes mesenterica and water in the head; and we have often been struck with the remark of parents and attendants about an hydrocephalic patient, 'that, considering he is so very ill, he has not lost much flesh;' a circumstance which, while it gives birth to hope on the part of friends, ought at least to excite suspicion in the medical attendant. The excretions of the bowels are sometimes perfectly black, and smelling like putrid mud; they are sometimes curdled with shreds of coagulating lymph, floating in a dark greenish-colored fluid. These appearances of the fæces are not observed in hydrocephalus internus.

'The convulsions,' the author goes on to say, 'which attend hydrocephalus, very seldom supervene, until the patient has been laboring for several days under evident indisposition, whereas they often usher in the very first attack of remittent fever.'

Causes.—Too much has been probably attributed in the present day to the state of the stomach, the bowels, and the hepatic viscera, as the media through which the affection now under remark is engendered; for though hydrocephalus is confessedly often a sympathetic malady, occasioned by the visceral irregularities in question, it is full as often, to say the least, an originally cerebral disorder, and the intestinal irregularities by which it is attended stand more in the relation of effect than cause of the brain disease. Even indeed when hydrocephalus is induced indirectly, through the medium of other affections, it is mostly so engendered by the affections of the absorbent system which commence in the mesentery, and extend as it were to the brain, rather than by those mechanical kinds of obstructed viscera which are chiefly supposed to be in fault.

In confirmation of this opinion, that hydrocephalus frequently commences in the head and not in the viscera, we shall repeat here the few positions that we have elsewhere urged for the purpose of establishing this assumption. First: We find the disease to be one principally of early life. It occurs ordinarily at some period during the growth and gradual evolution of the brain, before the organ has arrived at maturity, which circumstance would seem to favor the supposition of some organic alteration taking place of an original and independent nature; for impediments and interruptions must naturally be more incident to an organ during the process of development, than after the evolution is complete. Secondly: The malady is often connected with, and seemingly produced by, the process of teething, the irritation of which appears to extend itself to contiguous parts, and the brain comes to be affected by actual vicinity of position without reference to a distant organ. Thirdly: Were the complaint always, or more usually, brought about by obstructed viscera, we should expect to meet with it oftener in advanced life, when such obstructions are both more common, and more permanently operative, and then most obviously engender disorders in distant parts of the frame. Fourthly: We may observe that the subjects of hydrocephalus are, in the majority at least of cases, subjects in which a scrofulous tendency in the habit is more or less perceptible; and they are moreover those children in whom, from a precocity of intellect, we might expect brain functions to be inordinately active and complicated, and consequently more susceptible of disordered action.

But further; the frequently obvious causes of hydrocephalus are proofs of a too certain nature, that the complaint may, and often does, originate directly in the head. It has been suggested, by Dr. Wall of Oxford, whether the increased frequency of hydrocephalus of late years may not be traced to 'the leaving off the circular defence round the heads of children,' and their consequently more frequent exposure to injury from falls and blows. Whether this be the case or not, certain it is, and no practitioner of any experience will be inclined to dispute the truth of the statement, that external injuries, directly applied to the head, are often the immediately exciting sources of the disease; and this perhaps is the case much oftener than is seen or suspected. When the derangement has been thus certainly induced, in an immediate and direct way, we always see the functions of the bowels to be disordered in consequence; and may not this incidental and secondary affection be often in other cases taken for the cause, when it is rather the consequence? the torpidity or irregularity of the bowels being occasioned by that altered state of the brain, which is prior to the actual production of confirmed hydrocephalus. 'Anatomical dissections,' says Dr. Spurzheim, 'have convinced me, that in the greater number of cases the morbid appearances of the abdomen are secondary symptoms to those of the head.'

We, however, by no means wish to push our objections to the sympathetic theory too far. Derangements in the digestive organs, if permitted to go on without interruption, do often proceed to the length even of phrenitic hydrocephalus; and attention to the bowels in children with a view to prevent this result is highly important. In these instances, however, of secondary or resulting affection, we hold for the necessity of the scrofulous tendency being present to produce this specific effect; such tendency may not be very marked, but still it does exist: and upon the whole we would say, in reference to exciting cause, that dentition is the most common source of the disease, but that in the predisposed it may be engendered by almost any thing which shall disturb the balance of healthy functions.

Prognosis.—Exceedingly unfavorable. It is indeed questionable whether recoveries ever take place after effusion has been thrown out into the ventricles in any considerable quantity. Many, indeed, are the cases on record in which after the full trial of the mercurial plan, hydrocephalus in its very last stages has been cured; but there is always some reason to suppose that mistakes may have been made in reference to the actual condition of the brain supposed thus to be counteracted; for marks indicative of effusion o a considerable extent are, as in the case above elated, often present during life which are not manifested after death. We are disposed to think, when either art or nature does succeed in getting rid of the effused fluid, that a large flow of urine, or a very free diaphores, or a considerable diarrhœa, must be expected in the way of vicarious effect.

Treatment.—During the inflammatory stage bleeding and purging are to be had recourse to; but we must ever recollect that, notwithstanding the measure of inflammatory irritation, there is present a scrofulous debility which should in some degree stay the hand of depletion. Elaterium as a purgative appears applicable to the first stages of phrenitic hydrocephalus, since it produces a feeling of nausea, as well as occasions catharsis; and in this way absorption may perhaps be assisted. We rather wish, however, that the recommendation of elaterium should be received as a matter of experience, than upon any hypothesis as to its modus operandi. It scarcely need be stated that very small doses will be sufficient for a child, such as the sixth part or a quarter of a grain. Dr. Hooper recommends the croton oil, which has this advantage, that it can be put upon the child's tongue and thus brought to operate. We recollect seeing a child's life saved by merely smearing the tongue with the moistened cork from a croton oil bottle, and this after the power of deglutition, at least of swallowing any thing in much bulk, was gone. Digitalis and nitre may be administered to abate the febrile irritation and get down the inflammatory excitement.

℞ Pulv. potassæ nitrat. gr. vj.
Tinct. digitalis ♏ v—x.
Liq. ammon. acet. f. ʒij.
Syrup. croci. f. ʒj.
Aquæ distillatæ f. ʒv.

Fiat haustus; infanti ætat 4, adhibendus tertiâ quaque horâ.

Take of powdered nitre six grains, tincture of foxglove from five to ten minims, liquor of acetated ammonia two fluid drachms, syrup of saffron one fluid drachm, distilled water five fluid drachms. Make them into a draught for a child of four years; to be taken every third hour.—*Hooper.*

℞ Hydrarg. cum cretâ gr. ij.
Pulv. digitalis gr. ß.

Fiat pulvis; ter in die sumendus, ex quovis vehiculo crasso.

Take of quicksilver with chalk two grains, powder of foxglove half a grain. Make them into a powder to be taken three times a day in omething thick.

When the inflammatory stage is a little over, and even from the first showings of the disease, some practitioners commence immediately with mercury, under the notion that nothing else is to be depended upon. We wish we could conceive as favorably of the efficacy of this treatment as some practitioners seem to do.

℞ Hydrarg. submur. gr. ij.
Pulv. antimonialis gr. j.

Fiat pulvis, omni bihorio adhibendus ex quovis vehiculo crasso.

Take of calomel two grains, antimonial powder one grain. Make them into a powder, of which let one be taken every second hour in any thick vehicle. Anoint with mercurial ointment under the arms and in the groins.

Some have reported favorably of the effect of tinct. cantharid., and have joined deobstruents with it.

℞ Extract. taraxaci ℈ß.
Spiritûs ætheris nitrici ♏ xv.
Tinct. cantharid. ♏ iv.
Syrup. simp. f. ʒj.
Aquæ puræ f. ʒiiß.

Fiat haustus.

Take of extract of dandelion ten grains, nitric spirit of ether fifteen minims, tincture of cantharides four minims, simple syrup a fluid drachm, water two fluid drachms and a half. Make them into a draught.

Blisters may be applied to the nucha, but much is not to be expected from them. When there is much exterior heat about the head lotions may be applied, formed of spirits and water, or a solution of the muriate of ammonia, or vinegar and water.

It is often necessary to give opium to abate the irritations, and the best form of administering it under these circumstances is that of the pulv ipecac. comp., which may be combined with a small quantity of calomel. It is a fact worth attending to, that opium, in this form, will be borne by children when other preparations of it are inadmissible.

℞ Pulv. ipecac. comp. gr. ij.
Hydrarg. submur. gr. ¼.

Fiat pulvis; horâ somni sumendus.

Take of compound powder of ipecacuan two grains, calomel a quarter of a grain. Make them into a powder to be taken every night at bed time.

418. *Dropsy of the womb* (hydrometra) should rather be stated dropsy of the appendages of the womb, the ovaria (hydrops ovarii); for the collections in the womb itself, which give rise to the symptoms named in the definition, are not very common, unless as a consequence of false conception; in this case we have occasionally hydatid and other accumulations formed in the uterus, and retained by the production of an adventitious membrane or membranes.

Ovarian dropsy is of more frequent occurrence, and this it is sometimes difficult to distinguish from general dropsy in the abdomen. Of this affection Boerhaave, in one of his aphorisms, says, difficulter cognoscitur, curatur verò nunquam. It attacks usually women at the time when the menstrual discharge is about to leave them, and

is most usually an affection of virginity or barrenness. This however is by no means universally the case; for we sometimes observe it to occur in females at the prime and vigor of life, and at the very time in which they are regularly conceiving and becoming pregnant. Although, as we have just said, a dropsy in one or other of the ovaria is not easily to be distinguished from a dropsical affection in the cavity of the abdomen, yet there are certain diagnostic characters between the one and the other disease, which it behoves the medical practitioner constantly to bear in mind, since it is often of much moment with regard to practice, and always as it relates to prognostic inferences, to judge correctly respecting the position and actual nature of the dropsical swelling. In the first place, then, let it be remembered that, although in the event the whole surface of the abdomen becomes almost equally tumefied by ovarian dropsy, at the commencement of the enlargement this swelling is decidedly more on one side than the other, which is not the case in abdominal dropsy or ascites. The enlargement is, secondly, more slow in its progress than in cases of ascitic swelling. There is, thirdly, for the most part, no œdematous swelling about the ancles and legs, which is a frequent concomitant of ascites; or, if this swelling do occur, it is more in one leg than in the other, and in this case the enlargement of the limb is more decided, extensive, and continued, than in the case of general œdematous tumefactions. Fourthly, the general health is not by any means impaired in proportion to the extent of the local disorder, as is the case in ascites. In the fifth place the urine is not, as in ascites, in particularly small quantities, until the bulk of the swelling becomes such as to impede the proper actions of the urinary bladder, and in this case it is rather a mechanical interruption to the discharge than any deficiency of secretion. Sixthly, thirst is by no means so urgent as it is in dropsy generally. Seventhly, there is an absence of those liver affections, and of that peritonæal tenderness, which we have before pointed out as very common concomitants of ascites, especially in advanced life; and, lastly, the fluid cannot so distinctly be perceived to fluctuate as when it lies loose in the abdomen, and constitutes the true ascites. There is a further distinction to be observed even in regard to the ovarian dropsy itself, namely, Is the fluid which is contained in the organ extended throughout its whole cavity, thus constituting one uniform cyst? or is the ovarium, converted into a congeries of small, complete, and independent cysts? This distinction it will be of practical consequence to aim at tracing, since an operation in one case to discharge the collected fluid might prove of considerable temporary service, whereas in the other case, that in which the cysts are numerous and independent of each other, a very small quantity of fluid might be evacuated only from the puncture, and the patient would scarcely receive even immediate and partial relief from the introduction of the instrument. The principal and almost only mean of à priori distinction in this case is, to pass the hand over the whole surface of the abdomen, and endeavour to perceive whether the tumefaction is uniform, and without irregularities; if not, and there are on the contrary protuberances and irregularities in the swelling, it will be fair to presume that the water is contained in separate cysts or cavities, each of which must be punctured before the fluid can be evacuated. 'These cysts,' says Dr. Baillie, 'have been occasionally confounded with hydatids (another disease to which the uterus is more especially subject), to which they bear some resemblance. They are however really very different. They have much firmer, and less pulpy coats, than the hydatids; they contain a different kind of fluid, and they are differently connected among themselves. Hydatids either lie loose with regard to any connexion with each other, or they enclose each other in a series; or small hydatids adhere to the coats of larger ones. Cysts of the ovarium adhere to each other laterally by pretty broad surfaces; do not envelope each other in a series; and appear to have no power analogous to generation like hydatids, by which small cysts are formed, that are attached to those of a larger size.' It appears not improbable that these cysts are formed by a gradual enlargement of the small vesicles which make a part of the natural structure of the ovaria. On the treatment of ovarian dropsy we have literally nothing to say. It is probable that the state of the organs, previous to the collection of fluid, is of an irremediable nature; certain it is, however, that we have no well authenticated cases of any actual absorption of the fluid, and reduction of the ovary to its natural state, by means of medicinals of any kind. Tapping is a temporary remedy when the cyst is single, and it is perhaps more likely to be attended with unexceptionable benefit in some cases than even in general dropsy of the abdomen, since the tendency to peritonæal inflammation is not so great, the malady being of a more topical, and less complicated nature. Professor Morand asserts that he several times performed this operation on a lady of quality, who suffered so little from it, that she frequently went into the country the day after the operation, although generally eighteen pints of water were drawn out; nor did she die at last of dropsy, but of some other disease.

It should be observed that although an ovarian enlargement is for the most part a dropsical affection, it is not so without exception. There is a species of schirrous increase in the bulk of one of the ovaria sometimes to be met with: this however, compared with ovarian dropsy, is most certainly a rare occurrence, and the complaint in such a case would be attended with more derangement of the general health than is found to be the case for the most part in dropsy of the ovaria. The swelling too would be less in bulk and more gradual still in its progress. We may remark, indeed, that the ovaries are obnoxious to several disordered conditions of an anomalous nature, and all, we believe, without remedy. Boerhaave and others talk of fomentations, and vapors, and the warm emmenagogue drugs, &c. but we are disposed to think that, when the patient recovers, we are more indebted to nature than to art for the performance of the cure.

Although this is not exactly the place to speak

of them, we may here take occasion just slightly to glance at those anomalous affections that are connected with the cessation of the menstrual discharge: we might go the whole round of diseases before we should exhaust this subject. The fact is that there are no constitutional affections but what are likely to make their appearance at this proverbially critical time in the life of a female. Thus gout, apoplexy, mania, asthma, dropsy, stomach and intestinal complaints, ulcers in the legs, and many other distempers, seem as it were to await this time to make their attacks on the constitution, 'hanc nacta occasionem,' as Dr. Heberden elegantly expresses it, 'de valetudine jam infirma facile triumphant, et stabile imperium constituunt.' As it relates to the treatment of these maladies nothing requires further to be said, in reference to their appearance at this particular period, than that the management of them should always have an especial view to the stoppage or not of the menses; and that local evacuations apportioned to the vicarious congestions induced are often demanded, not in order to lessen general plethora, but for the purpose of diminishing topical fulness or inflammation. Thus supposing a menace of apoplexy to occur, upon the sudden disappearance of the monthly discharge, we should be called upon more imperiously to detract blood from the vessels of the head than in common cases of the same disorder at an advanced period of life; and purgatives especially are almost without exception called for in instances of this nature. The drying up too of ulcers, or the precipitate stoppage of natural evacuations, must in the state of things be very guarded and gradually done, and in fact the general principles of treating diseases at this juncture is that which the disciples of the Boerhaavian school of medicine would call deobstruent.

419. *Anasarca.* Dropsy of the flesh.—Before quitting the subject entirely of dropsical affections we are called upon to say that a mere dropsy of the flesh sometimes occurs without being accompanied by any visceral disorder—for the most part, however, it is the result of or attendant upon these last, and constitutes merely one of the marks of an exhausted frame and interrupted circulation. On this head we shall again make use of Dr. Hooper's instructions by extracting the section of his book which relates to it, and this we are induced to do from the opportunity it will afford us of presenting to the English reader the numerous prescriptions which are given by Dr. H., and which it may be observed are applicable in most cases to other kinds of dropsical accumulations as well as those for which they are more particularly inserted.

Symptoms.—The disease generally commences in the lower extremities, and first shows itself towards evening with a swelling of the feet and ancles, which by degrees ascends, and successively occupies the thighs and trunk of the body. When it has become very general the viscera are affected in a similar way; the cellular membrane of the lungs partakes the affection; the breathing becomes difficult, and is accompanied by cough, and the expectoration of a watery fluid. The urine is small in quantity, high colored, and deposits a reddish sediment; sometimes, however, it is of a pale whey color, and more copious. Costiveness; insatiable thirst; the skin is generally pale and arid; though sometimes a slight yet general inflammation takes place, when it becomes tense and shining. The water often oozes through the pores of the cuticle, or raises it in the form of small blisters; the countenance becomes sallow; torpor; heaviness, troublesome cough; slow fever.

Causes.—Predisposing. An hydropic diathesis, which is known by a loose flabby fibre, pallid and bloated countenance, the phlegmatic temperament, and scanty secretion of urine.

Exciting. Certain organic diseases, producing an obstruction to the free circulation of the blood; excessive discharges; suppression of customary evacuations; exposure to a moist atmosphere; the sudden striking in of eruptive complaints; crude and indigestible aliment; drinking large quantities of watery fluids; abuse of spirituous liquors; certain preceding diseases, as inflammation, the exanthemata, especially scarlatina; jaundice, diarrhœa, dysentery, phthisis, gout, intermittents of long standing.

Proximate. Increased effusion; diminished absorption; or both united.

Distinctions.—From emphysema. By the swelling in anasarca being œdematous; in emphysema, elastic and accompanied with crepitus; by the particular state of the urine; and other symptoms above mentioned.

Prognosis.—Favorable. The disease having been induced by causes which admit of easy removal; the strength little diminished; the constitution of the patient previously unimpaired; the appetite remaining entire; the respiration free; no great thirst; a gentle moisture on the skin.

Unfavorable. Concomitant organic disease; great emaciation; erysipelatous imflammation; much drowsiness; petechiæ and ecchymoses; hæmorrhage; feverish heat; great thirst; quick small pulse.

Treatment.—Indications. 1. To evacuate the collected fluid. 2. To prevent its again accumulating.

The collected fluid is evacuated by,

1. Scarifications and punctures.
2. Blisters.
3. Friction.
4. Emetics, and nauseating medicines; especially antimonium tartarizatum and squills.

℞ Vini ipecacuanhæ f. ℥ß.
Tincturæ scillæ f. ʒij.
Fiat haustus emeticus.

Take of Ipecacuan wine a fluid half ounce, and tincture of squill two fluid drachms. Make an emetic draught.

5. Cathartics; of elaterium—gamboge—croton oil—jalap—colocynth—submuriate of mercury—gratiola—crystals of tartar

℞ Extracti elaterii gr. ij.
Sacchari purificati ʒj.

Optime terantur simul, dein in pulveres octo æquales dividantur, quorum capiat æger unum omni horæ quadrante donec adsit catharsis.

Take of elaterium two grains, purified sugar a

drachm. Let them be well rubbed together and divided into eight equal parts, and let one be taken every quarter of an hour till they operate by the bowels.

℞ Extracti colocynthidis compositi
Extracti jalapæ, āā ʒj.
Gambogiæ ℈ß.
Olei juniperi ♏iv.

Fiant pilulæ xij. quarum capiantur tres omni hora donec alvus ter quaterve respondeat.

Take of compound colocynth extract and extract of jalap of each a drachm, gamboge ten grains, oil of juniper four minims. Make the mass into twelve pills, of which let three be administered every hour until three or four evacuations by the bowels are produced.

℞ Hydrargyri submuriatis gr. v.
Confectionis rosæ q. s.

Fiat pilula mane sumenda cum haustu cathartico salino.

Take of calomel five grains, conserve of roses sufficient to make a pill, to be taken in the morning with a saline cathartic draught.

℞ Pulveris scammoniæ compositi ℈ß.
Hydrargyri submuriatis gr. v.

Fiat pulvis catharticus.

Take of compound powder of scammony ten grains, calomel five grains. Make them into a cathartic powder.

℞ Extracti gratiolæ gr. xv.
Tincturæ sennæ f. ʒij.
Infusi sennæ f. ʒxj.
Syrupi zingiberis f. ʒij.
Potassæ sulphatis ℈j.

Fiat naustus catharticus.

Take of extract of hedge hyssop fifteen grains, tincture of senna two fluid drachms, infusion of senna eleven fluid drachms, syrup of ginger two fluid drachms, sulphate of potass a scruple. Make them into a draught, for a purgative dose.

℞ Herbæ gratiolæ incisæ ℥iij.
Foliorum sennæ ℥iß.
Extracti glycyrrhizæ ℥iij.
Electuarii cassiæ ℥ij.
Aquæ distillatæ Ojß.

Leniter coque per quadrantem horæ addendo sub finem coctionis,

Myrrhæ optimæ f. ʒj.
Potassæ sulphatis ʒiß.

Cola pro usu: et sumat æger cyathum parvum pro re nata.

Take of hedge-hyssop cut into slices three ounces, senna leaves one ounce and a half, extract of liquorice three ounces, cassia electuary two ounces, distilled water a pint and a half. Gently boil them for a quarter of an hour, and towards the end of the coction add myrrh a drachm, sulphate of potass a drachm and a half. Strain for use, and let a small spoonful be taken occasionally.

℞ Potassæ supertartratis ℥ij.
Pulveris zingiberis ʒj
Syrupi ejusdem q. s.

Fiat electuarium molle, de quo capiat æger cochleare minimum ter quaterve in hora donec alvus copiose respondeat.

Take of crystals of tartar two ounces, powder of ginger one drachm, syrup of ginger sufficient to form an electuary, of which a tea spoonful is to be taken three or four times in the hour, until copious evacuations from the bowels are produced.

6. Diuretics; of colchicum, scilla, acetas potassæ, digitalis, supertartras potassæ, spiritus ætheris nitrici, cantharis, juniperis, armoracia, sinapis, genista, lactuca virosa, tabacum.

℞ Tincturæ colchici f. ʒß.
Syrupi aurantii f. ℥jß.

Fiat syrupus, cujus sumat æger cochleare minimum omni bihorio, vel subinde, donec nauseam promoveat.

Take of tincture of meadow saffron half a fluid ounce, syrup of orange peel a fluid ounce and a half. Make a syrup, of which a tea spoonful is to be taken frequently, till nausea is produced.

℞ Pilulæ scillæ gr. x.

Fiant pilulæ duæ sexta quaque hora sumendæ.

Take of squill pill ten grains. Make two pills to be taken every six hours.

℞ Pilulæ scillæ gr. vj.
Pilulæ hydrargyri gr. ijß.

Fiat pilulæ duæ nocte maneque capiendæ.

Take of squill pill six grains, blue pill two grains and a half. Make two pills to be taken night and morning.

℞ Pulveris digitalis gr. j—ij.
Hydrargyri submuriatis gr. ¼—ß.
Pilulæ scillæ gr. vj.

Fiat bolus ter in dies adhibendus.

Take of powder of foxglove from one to two grains, calomel from a quarter to half a grain, squill pill six grains. Make them into a bolus to be given three times a day.

℞ Pulveris scillæ gr. j—iij.
Pilulæ hydrargyri gr. ijß.
Extracti taraxaci gr. vj.
Olei juniperi ♏j.

Fiant pilulæ duæ ter in die sumendæ.

Take of powder of squills from one to three grains, blue pill two grains and a half, extract of dandelion six grains, oil of juniper a minim. Make two pills to be taken three times a day.

℞ Infusi armoraciæ compositi f. ʒxij.
Spiritûs juniperi compositi f. ʒij.

Fiat haustus ter in die sumendus post pilulas diureticas.

Take of compound infusion of horse-radish twelve fluid drachms, and compound spirit of juniper two fluid drachms. Make them into a draught, to be taken three times a day after the diuretic pills.

℞ Infusi armoraciæ compositi f. ʒxij.
Spiritûs ætheris nitrici f. ʒj.
Syrupi aurantii f. ʒj.

Fiat haustus ter in die sumendus.

Take of compound infusion of horse radish twelve fluid drachms, nitric spirit of ether one fluid drachm, syrup of orange peel one fluid drachm. Make them into a draught to be taken three times a day.

℞ Tincturæ scillæ ♏ xx.
Potassæ subcarbonatis gr. vj.
Misturæ camphoræ f. ℥xij.
Syrupi zingiberis f. ʒj.
Fiat haustus ter in die sumendus.

Take of tincture of squills twenty minims, subcarbonate of potass six grains, camphor mixture twelve fluid drachms, syrup of ginger one fluid drachm. Make them into a draught to be taken three times a day.

℞ Aceti scillæ f. ℥ß.
Spiritûs ætheris nitrici f. ℥iß.
Misce: capiat cochleare unum minimum ter in die ex quovis vehiculo idoneo.

Take of vinegar of squills a fluid half ounce, nitric spirit of ether a fluid ounce and a half. Mix them; let a tea spoonful be taken three times a day in any convenient vehicle.

℞ Potassæ acetatis ℈j.
Infusi quassiæ f. ℥xij.
Tincturæ digitalis ♏ x.
Fiat haustus ter in die capiendus.

Take of acetate of potass twenty grains, infusion of quassia twelve fluid drachms, tincture of foxglove ten minims. Make a draught to be taken three times a day.

℞ Potassæ subcarbonatis ℈j.
Acidi acetici ferventis q. s. ad saturationem alkali.
Misturæ camphoræ f. ℥x.
Tincturæ digitalis ♏ x.
Syrupi zingiberis f. ʒj.
Fiat haustus ter in die sumendus.

Take of subcarbonate of potass a scruple, warm vinegar sufficient to saturate the potass, camphor mixture ten fluid drachms, tincture of foxglove ten minims, syrup of ginger a fluid drachm. Make them into a draught to be taken three times a day.

℞ Potassæ supertartratis ʒj.
Potassæ sulphatis gr. x.
Pulveris rhei gr. v.
Fiat pulvis ter in die sumendus.

Take of crystals of tartar a drachm, sulphate of potass ten grains, powder of rhubarb five grains. Make them into a powder to be taken three times a day.

℞ Tincturæ cantharidis ♏ xxx.
Spiritûs ætheris nitrici f. ʒj.
Misturæ camphoræ f. ℥xij.
Syrupi zingiberis f. ʒj.
Fiat haustus ter in die sumendus.

Take of tincture of cantharides half a fluid drachm, spirit of nitric ether a fluid drachm, camphor mixture twelve fluid drachms, syrup of ginger one fluid drachm. Make a draught to be taken three times a day.

℞ Tincturæ nicotianæ ♏ x—xxx.
Infusi gentianæ compositi f. ℥vj.
Aquæ pimentæ f. ℥x.
Fiat haustus ter in die sumendus.

Take of tincture of tobacco from ten minims to half a fluid drachm, compound infusion of gentian six fluid drachms, pimento water ten fluid drachms. Make a draught to be taken three times a day.

℞ Extracti lactucæ virosæ ...
Fiant pilulæ duæ ter in die capiend...

Take of extract of strong scented let... grains. Make it into two pills to be taken ... times a day.

℞ Extracti lactucæ virosæ ℈iß.
Infusi gentianæ compositi f. ℥x.
Aquæ menthæ piperitæ f. ℥iv.
Spiritûs juniperi compositi f. ʒj.
Fiat haustus ter in die sumendus.

Take of extract of strong scented lettuce halt a drachm, compound infusion of gentian ten fluid drachms, peppermint water four fluid drachms, compound spirit of juniper one fluid drachm. Make a draught to be taken three times a day.

℞ Radicis armoraciæ excisæ ℥ij.
Seminis sinapis ℥iß.
Baccæ juniperi contusæ ℥iij.
Vini albi hispanici Oiij.
Digere per dies octo, dein cola: capiat æger cyathum parvum vinosum bis quotidie.

Take of sliced horse radish two ounces, mustard seed one ounce and a half, bruised juniper berries three ounces, white wine three pints. Digest them for eight days; then strain, and let a small wine glassful be taken twice a day.

7. Diaphoretics; compound powder of ipecacuanha; camphor; antimonials assisted by tepid diluents; the vapor bath; the copious use of aqueous diluents; water impregnated with tinctura ferri muriatis.

8. Bandages.

9. Mercury; so exhibited as just to affect the gums.

The second indication demands,

1. A light nourishing diet, with pungent aromatic vegetables; garlic, mustard, onions, cresses, Rhenish wine.

2. Tonics; cinchona, cascarilla, cusparia, quassia, preparations of steel, as recommended for dyspepsia.

3. The occasional use of diuretics and aromatics.

4. Regular exercise.

5. Cold bathing.

423. *Physcony.* Physconia.—These hard swellings of the abdomen are often exceedingly obscure in their pathology, and generally irremediable, unless attacked on their onset by mercurial medicines given to a considerable extent, so as to excite the action of the absorbents.

424. *Rickets.* Rachitis.—The irregular bony formation, the large head, flattened ribs, tumid abdomen, and general emaciation, which characterise this disorder, are not nearly so common as they were formerly; and part of the immunity is, we believe, attributable to the improvement which has recently obtained in respect of the diet and management of infants; to our having come to employ food less copiously, and fresh air more freely. This disease undoubtedly depends upon a faulty and irregular deposit of the matter which forms bone, and we should regard it but as a higher degree of mesenteric atrophy. It is a curious circumstance, with respect to rickety children, that the earthy base of which the bones are formed, is occasionally

found in the urine and other parts of the body, so that the malady is partly in consequence of there not being sufficient energy in the system to convey the earthy phosphates to their appropriate situation, and partly to the deficient formation of the matter constituting bone.

Causes.—Rickets is an hereditary disease in some families, though parents that have been affected with it have sometimes a healthy and robust offspring. 'In some instances,' says the author from whom we now extract, 'it may, I think, be traced to a venereal taint, which, though not the immediate cause, is very often an exciting one of it and scrofula. At least, it is certain that syphilis, transmitted from parents to their children, appears in the latter in a manner very different from that in which the former are affected. We find that the children of the indigent and the profligate are those most generally affected with rickets; but at the same time it must be allowed that there are many circumstances which conduce to this disease, such as damp and cold residence, impure air, inattention to cleanliness, bad nursing, want of due exercise, a deficiency of food, and debility. Difficult dentition, and the pain and bowel complaint arising from it, may favor in a powerful measure the action of the exciting cause of rickets.'

Treatment.—'The indication,' says another author, 'is by bracing the system, especially the lymphatic part of it, to promote due assimilation of the ingesta, and the consequent osseous formation.

'Purgatives of the deobstruent kind are called for, that is, those which rouse the secreting and assimilating energy. The hydrargyrus cum cretâ of the pharmacopœia is an excellent medicine; this, in combination with very small doses of powder of digitalis, should be given every night for some length of time; and the practitioner will often be surprised at the beneficial effects of this combination. It will be necessary to interpose about twice a week a calomel purge in the morning.

℞ Hydrargyri cum cretâ gr. iij.
Pulveris digitalis gr. ¼.
Fiat pulvis; omni nocte administrandus.

Take of quicksilver with chalk three grains, powder of fox-glove a quarter of a grain. Make them into a powder to be taken night and morning.

℞ Hydrargyri submuriatis gr. ij.
Pulveris jalapæ gr. iij.
Pulveris zingiberis gr. j.
Fiat pulvis; bis in septimanâ exhibendus.

Take of calomel two grains, powder of jalap three grains, of ginger one grain. Make them into a powder to be taken twice a week in the morning.

'With wholesome food, such as biscuit, good milk, arrow-root, rusks, and rice, good nursing in the open dry air being at the same time enjoined, the above medicinals will sometimes prove every thing that is wanting. When, however, by these means, the secretory and assimilating organs are got into a better state, chalybeate medicines may prove highly useful. Of these the vinum ferri, the carbonas ferri, and the tinctura ferri muriatis, are the best. The dose of the first to a young child is half a drachm; of the second two or three grains, with an equal quantity of powdered rhubarb; and of the third four or five minims.

'It is often proper to correct the acidities of the first passages, by small doses of soda, or potass, or magnesia; but the phosphates of soda and lime, which were introduced into practice some time since, are of little avail.

'The sulphate of quinine, in half grain, or grain doses, might be tried with a promise of advantage.

'Cold and sea-bathing are efficacious, should the system not be too debile for their employment.

'A small quantity (say half a glass) of good port wine will sometimes prove very serviceable to children that are rather more advanced, but who still show a rickety tendency, by the ancle and wrist bones continuing to be enlarged unduly.'

Those deformities which are met with in the Alpine valleys, deformities both of mind and body, have been considered as instances of rickets in an extreme degree. There has been, and still continues to be, a diversity of opinion respecting the actual source of cretinism, as it is called, some placing it in the water, and some in the air; some attributing it to physical, some to mental causes; and since the subject is at the same time full of interest, and as just hinted sub judice, we shall here add some remarks from two modern authors in reference to this particular modification of disorder, or this humiliating exhibition of debility and monstrosity.

'Cretinism (which is to be met with very generally among the inhabitants of that part of Switzerland nearest to Italy, in the deepest valleys of the Alps, where the atmosphere is extremely humid, in consequence of numerous waterfalls and rivulets that emit powerful exhalations through the influence of the sun's heat, while they are excluded from the access of every drying wind) is a disease which has been supposed to be only as high a degree of rachitis as human nature can possibly sustain. This opinion is corroborated by an observation that the different stages or degrees of the evil correspond with the variations in the atmosphere. Those, for example, who inhabit the deepest and most recluse valleys are reduced to the lowest state of imbecility and idiotism; in those who are somewhat more elevated the mental powers are not so completely obtunded; and others still more elevated, and of course less exposed to exhalations, will probably be deformed merely with wens or swellings about the joints, and other symptoms of rachitis. Those who are nearer to the summits are perfectly exempt from all these appearances.

Cretinism is, in many instances, connected with goitre or *bronchocele* (see this disease). An enlargement of the thyroid gland is indeed a striking feature in the unsightly aspect of the cretin, but it is not a constant attendant; for cretinism is frequently observed without any affection of the thyroid gland, and this gland is often much enlarged without any affection of the intellectual faculties.

The production of cretinism by the bad quality of the air and food, the neglect of moral edu-

cation, and other evils attendant upon poverty and indigence; and the deformity becoming so general in those regions by a seclusion from the rest of mankind, and by perpetual intermarriages, is supported by facts so strong and pointed, that the greater number of cases in mountainous districts may safely be ascribed to these causes, instead of the use of snow-water, as a few have supposed. That the use of snow-water produces either goitre or cretinism is an absurd idea; for persons born and living in places contiguous to the Glaciers, who drink no other water than what flows from the melting of snow and ice, are not afflicted with these disorders, and they are observed frequently in places where snow is unknown.

The causes of cretinism begin to operate upon the system soon after, and perhaps even before, birth; the want of energy in the parent is communicated to the offspring, the children become deformed and cachectic very early in life, the growth and development of the body are impeded, the abdomen becomes enlarged, and the glands swelled in various degrees; moreover, the powers of the mind remain dormant, and are at length obliterated, partly from the want of proper organisation, and partly from the total neglect of every thing like education.

The head of the cretin is deformed, his stature diminutive, his complexion sickly, his countenance vacant and destitute of meaning, his lips and eyelids coarse and prominent, his skin wrinkled and pendulous, his muscles loose and flabby, and frequently he is affected with an enlargement of the thyroid gland or goitre, which greatly adds to his unsightly aspect. The qualities of his mind correspond to the deranged state of his body, and the disease prevails in all the intermediate degrees from excessive stupidity to complete fatuity.

Cretinism was observed in Chinese Tartary by Sir George Staunton, in a part of that country much resembling Savoy and Switzerland in its Alpine appearance. Dr. Abercrombie mentions, that many cases of it are to be met with in the Pyrennees, and les Cevennes of France.

A race of cretins existing in the south of France has lately been presented to the notice of the profession, under the appellation of Cagotts. In this part of France this degraded race is widely extended; the individuals of it, deformed with bronchocele, have an indistinct articulation, an air of stupidity, a sallow complexion, and an extreme apathy to all external objects. The Cagotts are pretty much the same as the Cretins of the Alps; they both present the same degree of imbecility, the last remains of the intelligence of man, together with the last traces of the human form.'—*Thomas.*

'Before taking leave of Switzerland, I may be permitted to make a few remarks,' says Dr. Johnson, 'on those two blots on the physical and mental organisation of men in these interesting regions—bronchocele (goitre) and cretinism. However salutary and delightful it may be to travel among the Alps, a residence of any duration there is attended with considerable danger, at least to young people, as will be presently seen.

In respect to the goitre, or swelled neck, a great variety of opinions have been broached as to its cause. The snow-water, the air of the deep valleys, and the food of the inhabitants, have, each in turn, been accused of producing this singular deformity—a deformity, by the bye, which is far from being uncommon in some counties of England, especially in Derbyshire, Nottinghamshire, and Sussex. As to diet, it may be observed that goitre is found to be infinitely more prevalent in some parts of Switzerland than in others, though the diet is the same, or nearly so, in all. For instance, in the valley of the Rhone we see hardly any thing else than cretins and goitres; while in the valley of Chamouni, separated only by the Col de Balme from the other valley, we see very few of either diseases. This contrast must arise, therefore, from something in the air or water, or both—for the food and mode of living are the same. Moreover, we trace bronchocele along the whole course of the Rhine, from Schaffhausen to Cologne, its frequency gradually and progressively decreasing as we descend that magnificent stream. What can this be owing to? For my own part, after viewing, with no inattentive eye, the moral and physical conditions of those inhabitants of the Alpine regions where cretinism and bronchocele abound, I have come to the conclusion, that one of the main causes of bronchocele especially is to be found in the water, however much this cause may have been scouted by some medical and scientific travellers. I do not mean to say that it is the snow-water which has any thing to do with the complaint. But who can tell the thousand matters with which the Alpine waters are impregnated?—Every stream, great and small, that takes its origin from the glaciers, and other elevated crusts of ice or snow, becomes in a short time perfectly white with the particles which it wears from off every rock and mineral substance, in its noisy and precipitous route to the lakes below. Hence a bottle of water, taken from any of these streams, lets fall, on standing, a prodigious deposit of earthy and saline or mineral substances. When we consider the infinite variety of materials constituting the beds and banks of these Alpine streams, and see the quantity of detritus which they carry with them, and which is swallowed by the inhabitants, we can have very little doubt that such ingredients have no trifling influence on the physical organisation of man. This supposition is strengthened by the fact which I have just mentioned, that bronchocele gradually and progressively decreases, as we descend the Rhine—a river that rises in the Alps, and is chiefly supplied by Alpine waters. It is hardly necessary to observe that, as the river increases its distance from the Alps, it lets fall the matters with which it was impregnated, as well as becomes mixed with auxiliary streams from countries not Alpine. This change is remarkable also in the Rhone. The Upper Rhone, where it falls into the lake of Geneva, is turbid even to whiteness; but its waters, while nearly quiescent in the lake, become clear, and pass through the city of Geneva like translucent streams of bluish crystal. Among those who inhabit the banks and drink the waters of the upper or turbid Rhone (namely, in the Valais)

there are twenty cretins and goitres for one that can be seen on the lower or filtered Rhone, in its progress to the Mediterranean. Although I do not contend that all this difference is owing to the change in the waters, yet, taken in connexion with the Rhine, I think it forms a strong ground of presumption in favor of the goitrefactive (if I may use such expression), influence of Alpine waters. That the cause of bronchocele cannot be traced to sour bread, or indeed to any particular article of diet (the water excepted), at least in Switzerland, is proved by the fact, that English children (who live as well as people in England) cannot be kept long at Geneva, or in any other part of Switzerland, without having enlargements of the thyroid gland. This fact is well known to those English families who sojourn in that romantic country.

But, it may be asked, can the waters in Derbyshire, or other goitrous counties in England, be the cause of bronchocele? I may answer that it is much more probable that the cause of the disease should reside in the earth than in the air—and, if in the former, surely the water which we drink is the most likely vehicle for its conveyance into the constitution. There is a mineral or saline substance in nature which is capable of removing this swelling of the thyroid gland—for instance, iodine;—and why should there not be another saline or mineral substance which is capable of producing the said swelling?—The same valley which issues forth the miasma that causes ague, gives birth to the tree that furnishes the quinine, which cures the disease.

When on this subject I may remark that, from an attentive survey of the Alpine valleys, it appeared to me that cretinism and bronchocele were only two prominent features of one great physical and intellectual deterioration which pervades the inhabitants of scenes the most romantic, sublime, and beautiful, that human eye has ever yet beheld. It is not the swelled neck, the enormous head, and the vacuity of mind alone that arrest our attention in traversing the Alpine regions. The whole corporeal fabric, with all its intellectual prerogatives, is stunted, deformed,—and, as it were, absorbed. Well might Goldsmith say—

Man is the only plant that dwindles here.

Every feature and phenomenon of nature around is wild, grand, and impressive—while he who is master of the whole, and the alleged image of his Creator, is an abomination to the sight.'

422. Order 3. Impetiginous Disorders.—On this head we shall be exceedingly brief, since the ailments which are included under it are for the most part those which deform the skin, or appear as cutaneous affections, a subject which we shall consider, with one or two others, in the way of appendix to the nosology.

Scrofula, syphilis, scurvy, elephantiasis, leprosy, yaws plaited hair, and jaundice, are the genera of this order, and it is only upon the first, third, and two last genera that we are now called upon to descant. Syphilis being referred to Surgery, and the remaining genera to the general head of *cutaneous disorder*.

423 *Scrofula*.—Of scrofula we have already spoken in the introduction to the present class. Indeed it is the foundation as it were, and susceptibility to disordered action, rather than itself a disease—thus the varied modifications of disorder to which we have already alluded, as having in their manifestation considerable connexion with the states of the lymphatic system, are in truth so many indices of scrofulous temperament, and they have been made to come out into actual disease, by exciting causes happening to fall upon the scrofulous or lymphatic diathesis.

Causes.—The taint or the disposition, or that conformation of body which leads to lymphatic and glandular derangement, is evidently hereditary, as what disposition or tendencyis not? The dispute indeed respecting hereditary disorders seems idle in the extreme—no one will or can deny that the son and daughter bring with them into the world physical and moral dispositions, inherited from their parents, and the disposition readily to break out into any particular form of disorder is all, we should suppose, that any one would contend for. The exciting causes of scrofulous diseases are the excitants of disease generally, but cold and variable and humid climates are the hotbeds, if it is not a contradiction so to say, of scrofula. The disorder is excited both by pampering and starving, both by too rich and too poor a diet.

Treatment.—The treatment of suppurating lymphatic glands, which are the most common manifestations of scrofula, will be considered in the article Surgery. In respect to the medical counteractives of scrofula generally, they are all resolvable into the administration of those articles which impart tone and vigor to the system generally, and act peculiarly upon the lymphatic part of the organisation. It is usual for parents to send their scrofulous children down to the sea-side, but there does not seem any specific virtue connected with a residence on the sea-coast; and it can only be considered useful in scrofula, inasmuch as any thing is likely to be serviceable that braces and strengthens the frame. Steel and bark are used with this intention; the sulphate of quinine in small doses may occasionally prove very advantageous. For the remaining few remarks which we have to make, on the subject of remedies for scrofula, we shall again draw upon the Compendium of Medicine.

The ammoniated iron, or the carbonate of the same metal, three or four grains of the former, or four or five of the latter, may be given to a child four or five years old, with a grain or two of rhubarb added to each dose.

Respecting the specific virtues of muriate of barytes and lime, about which there was much talk some few years since, I am sceptical; their efficacy, if they have any, is resolvable into tonic agency, and corrective operation upon the first passages.

When, in after life, scrofulous appearances are complicated with syphilitic taints, the decoctum sarsaparillæ compositum may, perhaps, be administered with advantage; administering at the same time five grains of the pilula hydrargyri submuriatis compositæ, every night.

Soda may be employed, together with the

conium and hyoscyamus, in the management of scrofulous disorders, that consist at once of derangements in the stomach and bowels, and local affections.

> ℞ Sodæ subcarbonatis exsiccatæ ʒj.
> Extracti hyoscyami,
> Extracti conii, āā ʒß.
> Pulveris rhéi gr. xv.
> Mucilaginis acaciæ q. s.
> Fiant pilulæ xxx.; sumat ij. ter in die.

Take of dried subcarbonate of soda one drachm, extract of henbane and hemlock of each half a drachm, powder of rhubarb fifteen grains, mucilage enough to make thirty pills; two to be taken three times a day.

From ten grains to a scruple of the spongia usta are given in cases of glandular affections, made into a powder with sugar; and iodine in different forms has recently been much lauded, especially in that enlargement of the thyroid gland which constitutes bronchocele; and which, perhaps, principally depends upon the same cause as the disorder of the lymphatic glands. See *Dr. Gairdner's pamphlet on Iodine in Bronchocele, Scrofula*, &c.

424. *Scurvy*. Scorbutus.—This is one of those diseases which demonstrate in a marked manner the influence which the depressing passions possess, not only upon the nervous organization, but upon the blood-vessels and general frame; for its great remedies, as it has been expressed by a writer whom we have often quoted in the present article, are 'change from despondency to hope, from filth to cleanliness, and from cold and damp to a temperate and dry climate.'

The disease, however, in its true and legitimate character, seldom appears but at sea, and is manifestly dependent in a great measure upon a long course of salted, dry, and putrid provisions; its symptoms, when occurring in this full extent, are, besides those put down in the definition, spongy bleeding gums, great depression of the animal powers, fœtid excretions, and occasionally spontaneous hæmorrhages from the bowels, the nose, and even from the ears and finger extremities.

Causes.—To these we have just referred; in respect to its proximate cause we should say, that it mainly consists in a disordered state of the blood, which breaks down its crasis and renders it unfit for the supply of the several secretory and excretory organs; hence the emaciation and debility, hence the hæmorrhagic disposition, the fœtid breath, the offensive evacuations, and all the general symptoms which connect themselves with this disease. At the time when the chemical changes which take place in the blood, in the process of respiration, were the topics of particular interest, there was much crude theory proposed in the way of explaining disorders upon degrees of oxygenation and deoxygenation; and although, as we have said, some of these theories were vague and much wanting in the precision and completeness which should always attend the admission of premises and the deduction of inference, yet the speculations themselves were of service had they done nothing else but call attention to the chemical habits and conditions of the blood in reference to the atmosphere.

'Various theories have indeed been advanced with respect to scurvy. By Sir John Pringle it has been supposed to be owing to a putrescency of the blood. By Dr. Lind, Dr. Blane, and Dr. Millman, it has been looked upon as a disease of debility, having its origin in the weakness of the organs of digestion, or in the gradual diminution of the vital power by the remote causes; or that it is owing rather to a defect of nourishment than to a vitiated state of it. Dr. Trotter, reasoning from the experiments of Dr. Goodwin concerning the action of dephlogisticated air on the blood, infers that the black color of this in scurvy is owing to the abstraction of this principle (dephlogisticated air), and that fresh vegetables cure the disease by restoring to the blood this lost principle. Dr. Beddoes supposes scurvy to be owing to a gradual abstraction of oxygen from the whole system, just as death is produced in drowning, by withholding all at once the same substance from that blood which is to pass the posterior cavities of the heart. Of the two causes of scurvy, want of fresh vegetables, or want of air sufficiently furnished with oxygen, Dr. Beddoes thinks the latter is by far the most powerful. Captain Cook's unexampled success in preserving his crews from the scurvy, during his last two voyages, seems to have been owing in a great measure to his extreme care in keeping every part of the ship well ventilated. The crew on many occasions were reduced to salt provisions, and much longer out of sight of the land than many other ships which have been dreadfully afflicted with the scurvy. In his last voyage there did not appear among the men any symptoms of this disorder; and, in his second, only one man had it in any considerable degree.'

Diagnosis.—The fœtid exhalations, spongy gums, and depressed spirits of the patient laboring under scurvy distinguish it from other diseases; the purpura hæmorrhagica or petechiæ sine febre is perhaps more allied to scorbutus than any other affection, but it is without the above manifestation. When petechiæ occur in malignant fever, the prior pyrexia sufficiently marks the distinction.

Prognosis.—Should the exciting causes continue to act with much force, the prognosis is unfavorable; but it is remarkable how speedily the disorder, even at its height, will yield to change of circumstances, of air, and of diet.

Treatment.—Vegetable food and vegetable acids are the principal antiscorbutics; nitre is also a good medicine in scurvy; this, given in conjunction with Peruvian bark, will often be found very useful. Our author has proposed that ships should be provided with the concentrated preparation of bark, the sulphate of quinine. The mineral acids also as well as the vegetable are good antiscorbutics; but the great principle of preventive treatment is that of procuring a good supply of fresh animal and vegetable food; and preserving ships' crews from the habits which under all circumstances tend to engender disease, but under circumstances of deprivation greatly increase such tendency. On this head we shall take the liberty of again extracting some paragraphs from the comprehensive and useful work of Dr. Thomas.

In all long voyages it ought to be our object not only to find out and employ the most effectual means to cure the scurvy when it shows itself, but likewise to prevent its arising at all, as the taint never fails to give a fatal or malignant tendency to the other disorders incident to seamen, such as ulcers, dysentery, &c.; and, with this view, our preventive plan ought to commence from the first day on which the sailing stock of fresh vegetables and ship's beer is expended; since from many experiments it appears that much greater success is likely to attend our endeavours in this way, than by reserving them for the period in which the marks of a scorbutic diathesis begin to manifest themselves.

When, from a want of the proper precautions before pointed out, the scurvy makes its appearance among a number of men, be it on board of a ship or in a close garrison, we are then to counteract its effects, first by obviating the putrid state of the system, and secondly by restoring it to its former vigor.

The first of these is to be accomplished by a diet of fresh animal and vegetable food, but more particularly the latter, consisting of garden and water cress, mustard, horse-radish, common radish, scurvy-grass, celery, endive, and lettuces, all of which may be eaten in their crude state, together with spinach, beet, carrots, turnips, cabbages, cauliflowers, brocoli, asparagus, the young shoots of hops, &c., which may be prepared by any common process of cookery. To these may be added a free use of ripe fruits, especially those of a subacid kind, such as oranges, shadocks, and others of this class. For ordinary drink the patient may use milk, or its productions, as whey, butter-milk, &c., or else an infusion of malt or spruce.

Such things are, however, only to be procured on shore, and therefore cannot be obtained for a ship's crew, unless they remain in port. When at sea, other substitutes must be resorted to.

One of the most effectual of this kind has been found to be lemon-juice, with which most ships belonging to government, and bound on a long voyage, are, I understand, now supplied; and I am informed that the daily regulated allowance is now one fluid ounce, mixed with one ounce and a half of sugar. Where fresh vegetables are not to be obtained, we ought to have recourse to this. To render its effects more certain, and prevent it from irritating the bowels, we should mix it with a sufficient quantity of water and sugar, which will make a pleasant drink, usually known under the name of sherbet. If a due proportion of wine is added, it will render it still more antiseptic. The quantity of juice used, during the first three or four days, ought not to exceed two ounces daily, but it may afterwards be increased to three or four per diem.

In Dr. Trotter's Medicina Nautica is inserted a letter from Mr. A. Baird, surgeon to the Hector ship of war, communicating to him the wonderful benefit derived from the use of lemon-juice in a voyage to and from the East Indies, during which, although the scurvy became very prevalent, he did not lose a single man. His words are, 'When I consider the alarming progress which the scurvy was making among the Hector ship's company previous to the administration of lemon-juice as a preventive, the sudden check that disease met with afterwards, and the powerful effect of the acid in very bad cases, I think I shall not be accused of presumption when I pronounce it, if properly administered, a most infallible remedy both in the cure and prevention of scurvy.'

Where the fresh juice cannot be procured we may substitute, with the greatest advantage, the citric acid in a concrete form, as first prepared by Mr. Coxwell. We are informed by Dr. Trotter that he has experienced its powers against scurvy to be equal to any effect he has ever observed from the recent fruit in its most perfect state. Other practitioners have reported alike favorably of it. It takes from sixteen to eighteen parts of water to bring the concrete acid to the standard of lemon-juce. It is obtained after the manner of Scheele, by combining the fresh vegetable acid with lime, and then precipitating by means of the sulphuric acid. See Pharmacy.

Dr. Trotter observes, that government mistake in making their contract for lemon-juice for the use of the navy, as what is furnished is often adulterated with the acetous acid, and sometimes contains the pulp, which render it liable to ferment. Lemon, and lime-juice,' he says, 'should be procured in Portugal and the West Indies, and in each place be combined with calcareous earth. It may be imported in barrels, and in that state be sent to sea, when the separation of the liquid acid is so easy a process as to require no trouble, and the medicine will be always in the best state. Combined with calcareous earth, the acid will remain unchanged for a great length of time.

It has been common to employ the fossil acids in this disease; but there is some reason to doubt if they are of any service, and it is certain they are not effectual remedies. Moreover, they can hardly be thrown in in such a quantity as to be useful antiseptics.

In a Treatise on Scurvy, by Mr. D. Patterson, surgeon in the navy, we are informed, that, from certain reasons, he was induced to try a solution of the nitrate of potass in common vinegar in several cases of this disease, which, with inexpressible pleasure, he saw to succeed in every one of them; and from frequent trials of it he is convinced that the scurvy may be cured at sea without the assistance of recent vegetable matter. If this turns out as stated, the discovery will indeed prove of great national advantage.

Mr. Patterson supposes that the good effects of the nitrate of potass, in mitigating or removing the disease, are to be accounted for solely from the dephlogisticated or vital air it contains, and that it may be rendered more active by being combined with an acid. He allows common vinegar to be of little or no utility when given by itself; yet supposes, that, if it were charged with dephlogisticated or oxygen air, it might prove highly beneficial; and this he presumes to be effected by the addition of nitre. The following is his method of preparing this new remedy, and making use of it.

At first he dissolved two ounces of nitre in one

quart of the ship's vinegar, and gave half an ounce of the solution (which he named acidum nitrosum, or nitric vinegar) to some twice, to others thrice, in the day, and as frequently bathed their blotched and ulcerated limbs with the same. From the good effect it had, and from its not producing the smallest degree of nausea, colic, or diarrhœa, he was induced to augument the dose to an ounce, and to repeat it as often as before.

Finding by far the greater number of scorbutics who were under his charge bore the increased dose of the medicine without expressing the least uneasiness, he now, instead of two, dissolved four ounces of nitre in one quart of vinegar, and gave from half an ounce to two ounces of this strong solution twice, thrice, or four times in the day, if they were either blotched, stiff, or ulcerated. In this manner, we are informed, he continues to use it.

He adds, 'Some patients cannot bear the nitric vinegar without the addition of water; while others, without the least inconveniency, bear it undiluted. The discharge by stool, or the presence of gripes and nausea, guide me with respect to increasing or diminishing the dose of the nitric vinegar; but at the same time it is not a slight degree either of nausea, colica, or diarrhœa, that renders an alteration in the quantity of the medicine necessary. To a great number of scorbutic patients eight ounces of this strong solution, containing one ounce of nitre, have in the course of the day, as long as such a quantity was necessary, been administered to each with the greatest success. Also, a circumstance no less curious than pleasing, large and frequently-repeated doses of this medicine have been given in cases of dysenteria scorbutica; and instead of increasing I have always found it remove the disease. Sometimes, notwithstanding the free use of the nitric vinegar, I have known constipation take place to a considerable degree; in which case I have found intermediate doses of the potassæ supertartras necessary and highly advantageous. This very constipated state generally occurred where the disease was far advanced; but in a few particular cases in delicate habits, and where the disease was not far advanced, I perceived even small doses of the nitric vinegar ruffle the stomach and intestines; to prevent or remove which I have found two, three, or four grains of camphor, with each dose of the medicine, very effectual.'

The effects of this medicine are as follow:— 'During a course of the nitric vinegar the belly in general is kept gently lax; the discharge of urine is increased, and changes from an alkaline to a healthy nature; the skin becomes open and more agreeable to the touch; the chilness is changed to a pleasing warmth; and the pulse acquires steadiness and healthy strength. Sleep comes to be more and more natural. The sallow and the gloomy is gradually changed into a clear and cheerful countenance. By degrees the inflammation of the mouth and nose subsides; the gums heal and get firm. The lower extremities lose, faster than could have been supposed, their livid hue; they gradually become softer, less painful, and more flexible, and ulcers put on a healthy appearance and skin over. The great oppression about the breast and stomach gives way, and the cough and the breathing become less laborious. The appetite and the sense of taste are restored; the depression of spirits and the lassitude are not remembered; the strength increases, and at last health returns.'

Mr. Patterson, in comparing the effect of vegetable acid with that of the nitric vinegar, writes as follows:—'In the month of July, 1794, at sea, a small quantity of limes were purchased by order of admiral Murray, for the use of the scorbutics at that time on board; but, instead of depending altogether on their power, I gave them only to a certain number, on purpose to compare their effect with that of the nitric vinegar, which was more generally administered; and from what I have seen of both, and after having weighed all circumstances, I am at present inclined to decide in favor of the latter.'

Such is the report made by Mr. Patterson on the effect of these two acids; and as he seems to attribute the good effect of the remedy which he most approves of to the nitre it contains, and not to the vinegar, I beg leave, continues Dr. Thomas, to propose the following query:—Might not a solution of the nitrate of potass in lemon or lime-juice, which of themselves are powerful remedies in scurvy, be preferable to a solution of it in vinegar, or even to these acids given by themselves?

By the means which have been pointed out, together with some other auxiliaries, such as spruce-beer, fresh infusions of malt or wort, sugar, and the succus cochleariæ compositus, we are induced to suppose that we shall in most cases, even in those of a desperate nature, be able to obviate the putrid tendency of the system, and effect a cure. Introducing oxygen into the system by any kind of means may likewise prove a good auxiliary.

It appears that the gases were used by the celebrated navigator La Pérouse in his voyage round the world; but he very wisely observes, that bottles-full of them might be swallowed without doing seamen a thousandth part of the good they receive from good slices of roast beef, turtle, fish, fruit, herbs, &c.

425. *Plaited hair.* — Plica polonica or trichoma.—In some parts of the north of Europe, especially in Poland, this disease is endemic; it is a disease in which a matter issuing from the head is deposited upon the hair, and so binds or plaits it together, that it is impossible to unravel it. It would appear to be a malignant degree of the porrigo of authors.

Causes.—There is said to be some obscurity respecting the exciting cause of this affection, inasmuch as cleanliness and regular combing of the hair do not afford securities against its visits. It should however be observed, that, in the countries where this disorder is endemic, it spreads only among the lower classes of people, whose diet is poor and irregular, and whose habits are such as to encourage the spread of a contagious affection. It is said to be hereditary, or that a disposition to it is transmitted from parent to offspring; and what disposition, as we have just before enquired, is not so transmitted? It is, however, a curious fact, that strangers are not so

liable to the disease as the natives, although they may fall into the same habits of uncleanliness or neglect; thus it should seem that the endemial disposition requires some length of residence to become established. It is further stated, that, in the countries obnoxious to the malady, some of the lower animals become subiect to a distemper of a similar nature; so that upon the whole it should seem that the predisposition to be affected by the common excitants of the complaint has some connexion with the peculiarities of soil or air of the place.

Cure.—'Cleanliness is its great preventive and cure; the hair should be taken off; the head kept well washed with soap and water, and very small doses of mercury may be occasionally necessary to correct the disordered habit. Indeed, one general principle pervades the requisites in these cutaneous ailments; and, with little exception, what is serviceable to one is serviceable to all. Drugs without cleanliness would make a sorry figure in all cases.'

It seems that an opinion is generally entertained among the Polanders, that there is danger in cutting off the hair, and that promoting the cure by external remedies is totally erroneous. The following fact which is quoted by Dr. Thomas proves the error and absurdity of this notion.

Some years ago, one-third of the recruits of the regiments of artillery brought from South Prussia were attacked with plica polonica. An order was received from Berlin to send to that city all those that were infected, and to take care that the disease was not communicated to others. This order, it appears, was not agreeable to the commanders of companies, as it would have occasioned the loss of at least 200 young soldiers. M. Hœnel, sugeon-major to the artillery regiment, became mediator in the cause; he made the recruits be brought on the ramparts, and ordered that a general shaving should be made. In a little time, a pile of plica was accumulated; these trophies were then cast into a ditch, and the heads of the men carefully washed with soap and water daily for some weeks; by this simple method those dirty Polanders were speedily transformed into good soldiers, without having in the least suffered by the loss of this precious ornament of their heads.

426. *Jaundice.* Icterus.—Jaundice is characterised by a yellowness of the skin, and of the whites of the eyes; by fæces of a whitish color and clayey consistence; by urine of a yellowish or rather obscure red color, tinging with a yellow hue linen that is dipped in it; by lassitude and indisposition to exertion; and by a lowness of spirits. All these symptoms being easily referrible to that quantity of bile being in the liver and general system which ought naturally to flow through the intestines, but which is prevented from thus supplying the intestines by several sorts of impediments.

Hepatic inflammation continuing for a time unsubdued, the coats of the bile-ducts will thereby become thickened, their diameter in consequence materially diminished, and thus a species of jaundice produced of a permanent and incurable nature. That yellowness of the skin and general depression of the spirits which we sometimes observe as the result of a long continued course of indulgence in the free use of spirituous liquors may often be brought about at least partly upon this principle; but partly perhaps by the schirrous enlargement of a liver which has been subjected to repeated inflammations pressing upon and thus lessening the diameter of the bile-ducts, which state of the liver, besides producing a tardy secretion, thus occasions a tardy flow of the bile that is secreted, and it has hence time by congestion in the liver to get into the blood vessels by re-absorption or by reflux. When then we are called upon to treat jaundice, it is scarcely necessary to say how highly important it must be to learn with as much exactitude as may be the actual state, not merely of the passages through which the bile flows, but the condition itself of the organ by which the bile is secreted; that our indications of cure may be built upon some rational grounds, and that we may be able to foretel, with any thing like certainty, the continuance and event of the malady upon which we have to exercise our discernment.

The above kinds of jaundice are more or less of an incurable nature: of this disorder there are, however, some species in which the interference of art is signally and abundantly beneficial. Gall-stones or inspissations of the bile plugging up the duct, and thus preventing the passages of the fluid, and spasms on these ducts, are the sources of jaundice which are principally treated of as those which the practitioner of medicine will be called upon occasionally to detect and to obviate; but there is another species of the malady which has been properly enough called icterus mucosus, which is neither attended by pain as in gall-stones, nor by spasmodic affections, in which no gall-stones are observed in the fæces, but in which by cathartics a large quantity of viscid mucus will be discharged. Van Swieten talks of colluvies pituitosa in primis viis as often the cause of jaundice, and it most certainly is so without either gall-stone obstruction, or spasmodic attacks about the ducts. When with persons of sedentary habits and hypochondriacal temperament, the skin assumes a decidedly icteric hue, the urine becomes unusually high colored, the fæces lose their proper excrementitious character, and the mind is much depressed, we may refer the impeded flow of bile which is attendant upon this state of things, partly to a direct and immediate deficiency of action, and partly to an accumulation of viscidities about the mouth of the bile-ducts, preventing the due intestinal supply. This effect, says a modern writer, may be more readily conceived if we call to mind the very oblique direction in which the duct penetrates the coats of the intestine, and that it passes for a short space between two of them. When thus the mouth of the common duct is closed, we have commonly not only obstruction to the passage of the bile into the intestine, but of the pancreatic secretion, because most frequently the pancreatic duct enters the duodenum by the same orifice, and then, for want of these stimulant and detergent fluids, tenacious slime accumulates, and the disease goes on still increasing.

The next species of curable jaundice which we

shall notice is that occasioned by those concretions which are called gall-stones; and, when these are the cause of the symptoms, the progress and establishment of the disorder is very considerably different. In this case there is often violent and protracted pain in some part about the region of the liver, or rather in the upper part of the abdomen, following the course of the ducts. This pain often comes on suddenly and continues for some time before any appearance of jaundice denotes the true nature of the malady; and it is highly proper for the young practitioner especially to take due cognizance of this pain, inasmuch as from its violence it may be supposed to be an inflammation of the bowels, and decided upon as such when subsequent appearances shall prove the fallacy of the prescriber's opinion. Let then the following marks of distinction be duly observed between the pain arising from the passage of gall-stones, or from spasms about the gall-ducts, and that dependent upon an inflammation of the bowels. In the first place this gall-duct pain is for the most part rather higher in its situation than enteritic pain; it comes upon the patient suddenly without any preliminary marks of incipient inflammation, such as shiverings or rigors; and lastly, as the principal point of difference, let it be recollected that the pulse is never accelerated as in the same degree of pain of an inflammatory nature. It is very seldom indeed that the number of pulsations rises to more than 100 in a minute; they are for the most part much under, while, with the same measure of pain dependent upon actual inflammation, the pulse would invariably be running to 120 or 130. The pain too remits, especially if the obstruction be merely spasmodic, and even occasionally when there are gall-stones; but there is not this remission in inflammatory pain; and further the patient has an instinctive inclination to bend the body forward in order to obtain relief, which is also sometimes obtained by pressure upon the part contrary to what is observed in enteritis. But the difference with regard to the number of pulsations forms the surest criterion of distinction: and it has been well observed, by a writer on this subject, that the more exquisite the pain is, provided the pulse is below 100 in a minute, with the more confidence may we rely upon this diagnostic symptom; inasmuch as such pain could only arise from the inflammation of a membrane, in which case the pulse would far exceed the number above specified. Before we make any observations on the nature and composition of biliary calculi, we shall say a word or two further on the spasmodic jaundice of authors; this is sometimes unaccompanied by pain, and at other times attended by a pain almost as acute as in the instance of gall-stones passing through the ducts; it generally attacks individuals of a sanguine and irritable temperament, and is either produced by violent passions of the mind, or by sympathetic irritations, such as worms, or indigestible matter in the bowels: it is often exceedingly transient. Its existence has been confirmed by anatomical observations, since some dissections that have been made of persons dying with this species of jaundice upon them, have proved the non-existence of either calculi or any cause of mechanical obstruction. As, however, the ducts themselves are composed entirely of membrane, and are not muscular, they cannot well be conceived susceptible of spasmodic action; and when the obstruction is from this source the spasm must be supposed to take place at the part of the duodenum itself in which the duct enters in the oblique manner already described, and thus the spasmodic action of the intestine constitutes the obstructing cause.

Dr. Darwin attributes one species of jaundice to an inirritability as he calls it of the gall-bladder. The jaundice of aged people, and which attends some fevers, is believed to be caused very frequently by a palsied state of the gall-bladder.

Darwin, indeed, mentions the case of a gentleman between forty and fifty years of age, who had labored under the jaundice about six weeks, without pain, sickness, or fever, and had taken emetics, cathartics, mercurials, bitters, chalybeates, ether, &c., without any apparent advantage. On a supposition that the obstruction of the bile might be owing to a paralysis or torpid action of the common bile-duct, and the stimulants taken into the stomach seeming to have no effect, he directed half a score of smart electric shocks, from a coated bottle which held about a quart, to be passed through the liver, and along the course of the common gall-duct as near as could be guessed, and on that very day the stools became yellow; the electric shock being continued a few days more the patient's skin became gradually clear. Such cases as these ought to be had in recollection, since the multiplication of our resources when the common ones fail is always desirable, and, when we successfully have recourse to expedients that are a little out of the common way, the impression upon others is at once more favorable, and the satisfaction of our minds greater.

But, to revert to the subject of gall-stones we may observe in the first place upon the difficulty there is in conceiving the principle upon which these bodies are impelled through the duct, since there is no muscular power of propulsion, and since, even if there were, the propelling power would, as it has justly been observed, be as likely to push the body in one direction as in another; and all those medicines which are given for the purpose of irritating the duct into stronger contractions would be as likely to do good as harm. It would appear that the effect is produced by the pressure of the fluid bile from behind, and that thus the very size of the calculus serves at times to facilitate its own expulsion, since this à posteriori pressure is more likely to be effectual, provided the stony concretion so occupies the whole canal as not to permit the passage of any fluid bile between it and the inner sides of the intestine. Dr. Pemberton observes 'that this idea of the passage of a gall-stone may perhaps serve in some measure to explain the uncertainty in the power of emetics in forwarding a gall-stone. We all know that the effect of an emetic is not only to produce relaxation of the whole body, but also to increase the secretion of bile; this increased secretion of bile, if its exit be prevented,

will mechanically increase the distension of the duct, and thus will a passage be opened for the calculus. If this position be true, it will follow that an emetic cannot assist the expulsion unless there is a total stoppage of the duct; for, without this, the bile would pass off, and no distension take place. The frequent failure of emetics, in making any impression upon the disease, sufficiently argues a modification of the complaint over which they have no power. This state I take to be that in which the stone, in consequence of its angles, does not completely close the duct.' It is astonishing to what size gall-stones will sometimes pass through the duct without occasioning mechanical injury. 'I have in my possession,' says the author from whom we have made the above extract, 'the model of one, whose long diameter is two inches and a quarter, and whose short diameter is one inch and a quarter.' He conceives that in this case ulceration had taken place between the duct and the duodenum, and that thus an aperture was made for the stone to pass into the intestines. Of this, however, there does not seem to be any positive proof. But although it does not seem by any means certain that the gall-stone just mentioned made its way by exciting inflammation and ultimately ulceration, it is a fact that such events do sometimes follow upon the attempt at a passage of very large concretions. 'An interesting case,' says a modern author, 'of inflammation of the gall-bladder proceeding from biliary calculi, and terminating in suppuration, which at length pointed externally, came under my observation some years back. The patient was a woman of about forty years of age, who for a considerable time had been severely afflicted with pain in the stomach, febrile heat, faintings, and a purging. After a month or so there arose a swelling near the navel, which upon being opened discharged a quantity of yellow matter for many days. The pain becoming very acute in the tumor, the surgeon was induced to introduce his probe into the orifice of the wound, when to his astonishment he found a hard gritty substance at the bottom of it, which upon being discharged a few days afterwards proved to be a gall-stone of the size of a common nut. This was shortly succeeded by another, and in due time the woman's health was perfectly restored.'—*Thomas.*

Biliary calculi are supposed to be principally formed in the gall-bladder, for here the bile is more stationary and viscid; and, although the modus operandi of their production is obscure, it seems to be from irregularity in secretion and absorption. They consist, we are told by chemists, principally of that peculiar substance which Fourcroy calls adipocire. 'They are divisible,' says Dr. Thomson, 'into four classes. The first kind comprehends those which have a white color, and a crystallised, shining, lamellated structure. They consist of adipocire. The second species are polygonal of a light grayish-brown color. Externally they have a covering composed of thin concentric layers, within, a matter either crystallised or having the appearance of coagulated honey. They are also composed chiefly of adipocire, but contain a small portion of brown matter, consisting as it appears of inspissated bile. The third are of a brown color, and are supposed to be more decidedly formed of inspissated bile. (This kind of gall-stones is principally found in the inferior animals.) The fourth species comprehends those gall-stones which do not flame but gradually waste away at a red heat. The two first kind, or those constituted principally of adipocire, are those which are oftenest found in the human subject.' 'There is,' says Dr. Monro, 'a fifth but very rare kind of biliary calculi, which, as far as I know, has not been described, which is of a jet black color, of a shining appearance, and seldom attains a large size, and is very irregular on the surface. I have never seen such calculi but in the ductus communis choledicus.'

With regard to the *prognosis* and *treatment* of jaundice every thing of course must depend upon the nature of the obstruction which produces the complaint. Should there be reason to suspect schirrosities, as the result of gradual chronic inflammations of the liver, the malady is to be viewed as in a great measure hopeless, and the subject for the most part stands upon the brink of an abdominal dropsy by which he will sooner or later be carried off. That species, too, which depends upon the thickening of the villous coat of the gall-ducts, does not for the most part admit of much remedy; but in this case the jaundice is not always of so complete or so hopeless a nature; since, though the thickness of the ducts may remain, and thus impede the due supply of bile to the intestine, the obstruction is in no part of the ducts complete; and, with regularity of diet and habits, the liver may eventually come to accommodate itself as to the quantity it secretes to the quantity that can pass off.

It is in the three remaining sources of jaundice that we have a prospect of accomplishing much by medicine, and which when uncomplicated with any other affection are for the most part diseases of no very long continuance. When we imagine the obstructing cause to consist in duodenal viscidities or mucous obstructions merely at the entrance of the duct into the intestines, we must set about the administration of such medicinals as are calculated at once to purge off these viscidities, and restore the secretory power of the duct and intestines to their wonted tone. Emetics are often very useful in this species of jaundice, and they in some measure answer both the purposes of emulging and exciting new actions. The combination of purgatives with bitters, as mentioned under the head of *Stomach Affections*, will prove very useful in icterus mucosus. Should there be reason to suppose much hepatic torpor, the exhibition of calomel over night to be succeeded in the morning by a purgative will answer a very good purpose; this plan may be pursued once or twice a week, and some tonic bitter, such as quassia or gentian, be taken twice or three times a day during the time. This kind of jaundice is most usually brought on by sedentary habits, and mental depressions; regular exercise therefore, with the excitation as much as may be of pleasurable feeling, it is scarcely necessary to observe, are always desirable. This kind of jaundice may be distinguished from liver affection by the absence of those symptoms which

denote schirrous obstructions in this organ; it may be distinguished from the jaundice of spasm and gall-stones by the slowness of its approach, and by the subject of it being exempt from pain, at least when there is pain it has nothing in it of that acute and violent kind which gall-stones and spasm produce.

When the obstruction of the ducts is from gall-stones, and when these occasion that extreme pain of which we have above spoken, warm fomentation, or the warm bath, and opium, are the principal resources of the practitioner. The quantity of opium (says a modern writer) ought to have no limit but the abatement of the pain, and, till that object be effected, the patient should take a grain of solid opium, or twenty-five drops of tincture of opium every hour.' Enemas, too, composed of starch and about a drachm of tincture of opium, will frequently assist much in mitigating the sufferings of the patient; which it should seem is the principal thing that it is in our power to do, since, from what we have above observed, it is at least problematical whether an immediate and actual aid is given to the propulsion of the obstructing body by any medicinals which we employ. An emetic may indeed, as above hinted, assist its passage mechanically by occasioning a large secretion of bile; but we are for the most part disinclined to their employment, since the irritation excited by the pain is already so great as to induce a wariness in the use of any measures which are calculated to augment this systematic disturbance.

In the general way we should regard emetics as more precisely applicable to the icterus mucosus, than useful in facilitating the passage of gall-stones. There is a curious case related at length in Hoffman of an obstinate jaundice being cured entirely by emetics. This Hoffman treated as an instance of jaundice arising, as he expresses it, 'à bile copiosori, viscida, et in ductibus biliosis non minus ac intestino duodeno stagnante.' The subject of this attack took a scruple of ipecacuanha, and one of tartar emetic, which after the lapse of five days was repeated, and thus the cure accomplished.

With regard to the specific solvent power of any materials, inferred from the same effect being produced out of the body, the exercise of such solvent property when they are received by the stomach is, to say the very least, abundantly doubtful. Ether for instance, and spirits of turpentine, as well as the pure alkalis, and nitric acid, are all capable of dissolving the most usually found biliary concretions, and these have, therefore, in various forms been suggested as internal medicines in cases of biliary obstructions. Ether with yolk of egg is recommended, says Darwin, as having a tendency to dissolve inspissated bile. And a decoction of madder is recommended for the same purpose, because the bile of animals, whose food was mixed with madder, was found always in a dilute state. The same author speaks with others of the beneficial effects of raw cabbage, and other acrid vegetables, as water cresses and mustard. It is said that horses are subject to inspissated bile with yellow eyes, in the winter season, and to get well as soon as they feed on spring grass. The largest bile-stone, says Dr. Darwin, I have seen, was from a lady who had parted with it some years before, and who had abstained above ten years from all kinds of vegetable diet, to prevent, as she supposed, a colic of her stomach, which was probably a pain of the biliary duct. On resuming the use of some vegetable diet, she recovered a better state of health, and formed no new bilious concretions. M. Durande, a continental practitioner, affirms that he has cured all whom he met with suffering from gall stones, by a mixture of ether and spirit of turpentine; and Dr. Beddoes talks in high terms of a composition of soda and soap in the form of pills, as a remedy for gall-stones. If these medicines are endowed with the faculty of dissolving the concretions, it must of course be by a slow process, and they must therefore be looked upon rather as preventives than remedies. It is possible that the benefit attending the continued use of nitric acid in some kind of stomach pains may have some connexion with this counteracting power, and that both the pure alkalies and the mineral acid may thus serve as conservatories against the calculary tendency in the habit. It must be recollected, that although we have described the cases of gall-stones, which in their passage are accompanied by very excruciating pain, these concretions may, and do often pass of such comparatively small dimensions, and probably often of such yielding consistence, that pains of a much less violent degree are induced by their transmission, and which appear in the shape of cramps and spasms about the stomach attended by a jaundiced color of a very slight and transient nature. From the too hasty absorption, says Dr. Darwin, of the thinner part of the bile, the remainder is left too viscid and crystallised in lumps; which, if too large, obstruct the ductus communis choledicus, producing pain at the pit of the stomach and jaundice. When the indurated bile is not harder than a boiled pea, it may pass through the bile-duct with difficulty, by changing its form; and yet these viscid lumps of bile may afterwards dissolve, and not be visible among the fæces. The following observations of Dr. Heberden on this subject are worth attention. 'Among the various maladies,' says this observant physician, 'to which the human body is obnoxious, none are more frequent than pains about the stomach, which, if I am right in my judgment, do not seldom originate in a concretion of the bile (à bile concresente, vel coacta), although such concretions have not been equal to plugging up the bile-ducts, and producing jaundice. It is a long time, he says, that I have been induced to entertain this suspicion, and the observation of each passing year has served to confirm and strengthen it. For several individuals, who for months or years had suffered from this pain, I have known eventually to become affected with actual jaundice. On this account, he goes on to say, when I have observed such pains accompanied by a sense of weight about the stomach, which I have not been able to trace to any other source, I have conceived a tendency in the bile to inspissation, and I have in consequence ordered emetics, and the use for some time either of saline purgatives

or other aperient medicines.' Now it is in such semi-kind of concretions as these, if we may use the expression, that the protracted administration of either soap and soap pills, or the nitric acid, may exercise a preventive efficacy against the full formation of true biliary calculi; and generally, in instances where we have suspected the states in question, we have employed the soda pills especially with this intention; but we certainly are short of actual demonstration that the objects we desire to accomplish are thus effected. 'Tanto tamen opus est, ne nimium fidamus his rationibus,' says the author whom we have just quoted, when treating on the head of biliary preventives or solvents; and we must confess a greater disposition to side with him than to join in the enthusiastic encomiums of M. Durande.

In long protracted cases of jaundice, especially when the disorder is accompanied with much hepatic affection, and broken down energies, it is not seldom that discharges take place from the bowels that appear to consist of vitiated biliary secretions mixed with blood poured out from the meseraic vessels. This state of things would constitute the melæna of authors, and is named by the vulgar the black jaundice; considerable danger always accompanies this expression of disease, not so much from the loss of blood, or the extent of discharge of any kind from the bowels, as that it indicates a bad state of things internally, and is often indeed a mark of much visceral disorganisation. Its remedies are such as have already been spoken of under *Hæmatemesis.*

As this is the jaundice of old age, so is there one of infancy; which is, however, for the most part, of a trivial nature, and short duration; it is often caused by a retention of the meconium, and relieved by those gentle purgatives which remove the meconium from the bowels.

We here subjoin a summary of the remedial indications of jaundice, taken from the Compendium of which we have in the course of the present article made so much use.

'The great object of practice will be, to cause the bile again to flow freely into the duodenum and through the intestines; the cause of the obstruction must, of course, be sought for; if much pain is present, opium is loudly and imperatively demanded. From twenty to thirty drops of the tincture, or two grains of the solid opium, may be given every second or third hour, or oftener, till the pain subsides; and, although inflammation be not present, a preliminary bleeding may be sometimes advisable, in order to make way, as it were, for the free and full action of the opiate. Warm fomentations to the abdomen must be had recourse to; and, after the pain may have somewhat subsided, cathartic pills may be administered. These are the remedies for the active and painful form of the disorder. The more gradual and less acute kind calls for emetics and purgatives, and biliary solvents, according to circumstances. In the icterus mucosus, emetics are often exceedingly useful, they are best formed of ipecacuan; and in chronic cases of jaundice it will be sometimes found expedient to keep up nausea for some time. Blisters on the region of the liver, and sparks of electricity drawn over the right hypochondrium, have been known to emulge the bile, and cure jaundice when other measures have failed; when, as is often the case, a degree of chronic inflammation has been induced in the liver, from the interruption caused in its functions, the remedies directed under the head of *Hepatitis* are to be resorted to. Pills of soap and soda, equal parts, continued for some length of time, and combined with bitters and the taraxacum, have proved advantageous in correcting chronic jaundice. Turpentine, also, with ether, has been thought by some specifically operative in resolving biliary concretions. When the icteric disorders continue from mere debility, steel, with small doses of purgative salts, will be found of service. Thus Cheltenham waters prove beneficial to the semi-icteric state, that is connected with a chronic disorder of the liver, brought on by residence in tropical climates. Raw eggs are recommended by many, to be taken freely, when the purpose of the practitioner is that of procuring a deobstruent operation. The copaiba, too, which may be mixed with egg, is administered with the same intention.

℞ Copaibæ ♏ xxv.
Vitelli ovi q. s.
Spiritûs ætheris nitrici,
Spiritûs sulphurici, āā f. ʒß
Syrupi simplicis f. ʒj.
Aquæ puræ f. ℥iß.
Fiat haustus; bis terve in die sumendus.

Take of copaiba balsam twenty-five minims, yolk of egg a sufficient quantity, spirit of nitric ether and of sulphuric ether of each a fluid half drachm, simple syrup a drachm, water a fluid ounce and a half. Make a draught to be taken two or three times a day.

427. Class 4. Locales. Local diseases.—With jaundice Cullen's third class terminates, and with this also very nearly terminates our connexion with the nosology. It has already been remarked that the very notion of local disorder, excepting in cases of accidental lesion of structure, is in some measure an erroneous one, and, at any rate, most of the orders and genera included in the class locales, are subjects rather to be treated of in the article Surgery than requiring much discussion in this place. Thus the genera caligo, amaurosis, dysopia, pseudoblepsis, all disordered conditions of the visual organ, are disorders which are principally referred to the surgeon; the same may be said of the three following genera, dysecoia, paracusis, and anosmia,—the first two having to do especially with the ear and its appendages, the third with the nasal organ; the genera agheustia depraved taste, and anæsthesia deranged feeling, as it regards touch, are obviously referrible either to some disordered condition of the organs of taste and touch, over which the physician has not much control, or they are accidental expressions of other general or radical ailments, such as paralysis, which have already been dwelt upon.

428. On bulimia, or an inordinate appetite, we shall use the freedom of extracting from Dr.

Good, partly because the highly marked cases which occur of this disordered condition are objects of some curiosity, and partly because the remarks of our author on the bulimia of habit and idleness are well worth the regard of those for whom they are intended.

There are many persons (says Dr. G.) who from birth, or a particular period of life, without any habit of indulgence, are capable of taking into the stomach an enormous quantity of food, and cannot be satisfied without it, from a constant sense of faintness and inanition; and who by no means increase in bulk in proportion to the quantity swallowed; being often, on the contrary, slender and emaciated.

It is difficult to account for this effect in every case; but there is great reason to believe that in general it depends upon some error in the structure or position of the stomach, by which means the food passes out of this organ as soon as it is introduced into it. Thus Ruysch gives a case in which the diameter of the pylorus was considerably enlarged from relaxation; and there are others in which it has been changed from its natural to a lower or dependent position, in consequence of the left side of the stomach being elevated by a dropsy of the ovarium, or an enlargement of the liver. The existence of a double stomach, or of an immediate insertion of the ductus communis choledochus into the stomach, though noticed as causes by Blasius and Bonet, are more doubtful. In the hunger of general exhaustion, forming our third variety, we know it to be produced by the secretion of an extraordinary quantity of gastric juice, by which the food is digested almost as soon as it reaches the digestive organ. And it may sometimes, as supposed by Galen, be produced by some acrimony in the stomach, exciting that mimic feeling which is commonly known by the name of false appetite.

Whatever be the cause, the quantity of food devoured by persons laboring under this affection is enormous, and in some instances almost incredible. Dr. Mortimer relates the case of a boy of only twelve years old, who, from a feeling of inanition, had so strong a craving that he would gnaw his own flesh when not supplied with food; when awake he was constantly eating: the food given him consisted of bread, meat, beer, milk, water, butter, cheese, sugar, treacle, puddings, pies, fruits, broths, potatoes; and of these he swallowed, in six successive days, 384 lbs. 8 oz. avoirdupois; being sixty-four pounds a day on the average. The disease continued for a year: and in this case we have a clear proof that the feeling of hunger did not depend upon any extraordinary secretion of gastric juice producing a rapid digestion; for the food was usually rejected soon after it was swallowed, but whether without passing, or after having passed into the duodenum, it is impossible to say. And there are other cases related by Lommius of a similar kind.

In various instances, however, the food thus voraciously swallowed does appear to be digested, and that almost as soon as taken. The case of Tarare, as related to the National Institute, by M. Percy, a surgeon in chief to the French army, is a striking illustration of this. Before his enlistment he was in the habit of devouring enormous quantities of the coarsest flesh, fruits, and roots: and, subsequently, he was found, after swallowing his own rations, to feed on the refuse of his comrades' messes, or offensive meat thrown on the dunghills; and to devour cats, dogs, and serpents. He was strongly suspected of cannibalism; and was often restrained with difficulty from the ward appropriated to the dead. He at length fled from the army before a rumor of having devoured a child of sixteen months old, which had suddenly disappeared. The alvine evacuations of this man were not immoderate: but, after gorging his stomach, he slept and sweated in torrents of perspiration, a symptom common to the disease. He fell at length into a hectic, and died of marasmus.

Voracity is often a symptom of some other affection: it will sometimes occur, in the most capricious manner, during pregnancy, often in the middle of the night, or at some other unexpected period; when the patient, with a sudden sense of faintness and inanition, will perhaps devour an inordinate quantity of almost any food that can be obtained at the moment, though in many cases there is a fanciful longing for a particular kind, as for herrings; of which Talpius gives an instance of a lady, who in this state devoured 1400 at a meal. In these instances it is probable that the urgent desire becomes a stimulus to the secernents of the stomach, and that a greater quantity of gastric juice is in consequence poured forth.

In like manner voracity and the sense of hunger occur also as a symptom in many cases of helmintha, or worms in the stomach or duodenum. But, from the emaciation which usually accompanies such persons, it is most probable that the inanition or emptiness of the stomach is here produced not by a rapid or elaborate digestion, but by an irritable state of the muscles of the stomach, which contract too readily, and force the food into the intestines before chymifaction has taken place. Dr. Burroughs relates the case of a patient in the Philosophical Transactions, who, from this cause alone, was rendered capable of devouring an ordinary leg of mutton at a meal for several days together, and fed greedily at the same time on sow-thistles and other coarse vegetables.

Among the Greeks idiopathic voracity appears to have been a frequent disease: they paid much attention to it, and distinguished it by a variety of names, but do not seem to have been very successful in determining on the nature of its cause, or the best means of treating it. The last, indeed, must be as variable as the efficients that produce it. When we have reason to ascribe it to a morbid state of the stomach, in respect to tone or secretion, purgatives, and especially those that are warm and bitter, as aloes, may be found successful. Stimulating stomachics have been found equally so; whence Galen very judiciously recommends frequent and small doses of brandy; and Riverius, of ambergris. If these do not succeed, the stomach should be kept for some days in a state of constant nausea: and with this view, as well as with that of destroying the morbid irritation on which the voracity de-

pends, opium will often be found a highly salutary medicine. If the disease be produced by worms, or any other remote irritation, it is obvious that it can only be conquered by conquering the primary affection. And if it depend on a preternatural enlargement of the right orifice of the stomach, so that the food slips away as soon as it is introduced into this organ, a perfect cure is beyond the reach of art; though some benefit may be derived from a strong external pressure so as to detain the food in its proper place.

The second variety resulting from a gluttonous habit is far more common, and very rapidly produced; insomuch that there is not perhaps a corporate town in the kingdom that does not offer abundant examples of it. It is in fact one of the numerous evils to which idleness is perpetually giving birth: for let a man have nothing to do, and he will be almost sure, whenever he has an opportunity, to fill up his time by filling up his stomach: and hence the lazy train of servants that vegetate from day to day, almost without locomotion, in the vestibule, hall, and other avenues of a great man's house, eat three or four times as many meals as their masters, who may possibly be employed, from morning till evening, in the courts of law, the committee-rooms of parliament, or in a fatiguing maze of commercial transactions.

In tracing the cause of this voluntary disease we have no difficulty whatever. When the stomach becomes accustomed to distension it is never easy without it; and at length requires to be constantly full to be free from disquiet. It is also well known that every sense grows more acute the more it is employed: and hence the taste and longing of the glutton become more alive to what is relishing and savory: he enjoys such indulgencies more than other men, and turns with disgust from foods that are plain and simple: on this account the difference between the craving of a pampered appetite and that of real hunger is extreme. The former, whatever be its longing, can only satiate itself on delicious and high-seasoned dishes; the latter is content with a fare of any kind, and enjoys the plainest more than the richest.

It is not often that we are asked to attempt a cure of this complaint: it generally proceeds till the tone of the stomach is exhausted by its hard labor, and the cure is effected by the introduction of dropsy, or some other disorder worse than itself, which effectually extinguishes all appetite whatever. The man, nevertheless, who would honestly undertake to reclaim himself from this mischievous habit, and to acquire a better, should proceed in his career gradually; for organs that have long been under the influence of perpetual excitement, would lapse into atony upon the sudden adoption of a severe counterplan. The food should gradually be plainer, less in quantity, and repeated at a greater distance of time; while the intervals should be filled up with some pleasant and active pursuit that may wholly engross the attention; for the surest way for such a man to produce faintness, flatulency, and uneasiness in his stomach, is to think about it. The bowels will at first perhaps be costive: but this may easily be remedied by occasional doses of the warmer and bitter purgatives, as aloes, colocynth, and rhubarb; which will operate as usefully by their tonic, as by their aperient qualities.

The voracity produced by an exhausted state of the system is rarely of difficult removal; for, in general, it requires good plain food, and abundance of it. It is most usually consequent upon rapid growth of the body in the period of youth, fevers, excessive discharges, especially from the bowels or blood-vessels, long fasting, severe and uninterrupted exercise, and particularly the union of the last two, as often occurs in shipwreck, or the retreat of an enemy: it happens not unfrequently that in such cases the stomach occasionally overloads itself, and throws back some part of what has been swallowed. But this is of little importance, and often proves serviceable, by more effectually inculcating moderation than can be accomplished by medical precepts.'

In respect to the several disorders which follow the stomach affections, in this order of diseases, we shall here content ourselves with transcribing the following remarks, to be found in the Compendium of Medicine, to which we shall add those introduced likewise under the second section of this order; and as to the remaining items in this class, they will either be found, as we have above intimated, incidental manifestations of other maladies, and as such, to have already been treated of, or they will immediately be referred to in the appendix to the nosology; or else they are such derangements as, in the present day, are placed in the hands of the surgeon.

The intimations to which we have above alluded, are the following:—

429. *Lasciviousness.* Satyriasis. Nymphomania.—These ailments, connected with sexual peculiarities, often require a good deal of delicacy and discernment from the practitioner; many are the instances in which physical states have been considered moral derelictions; but, on the other hand, we must be careful of not running into the medical materialism of placing every thing to the charge of organic necessity. A proper regulation of the mind and moral sense will often do wonders. Let the feelings of the practitioner, however, always bear towards the material and merciful side of the question; and let him be ready to comfort the patient, whose organic disorder shall be kept up and increased by the erroneous conception, that he or she in being the subject of such disorder is then and therefore criminal.

430. *Anaphrodisia.*—This is often an imaginary affection and creates great uneasiness to the party or parties concerned. Dr. Darwin records two cases of youths who committed suicide under the erroneous conceit of being impotent; and John Hunter relates a most instructive case in which temporary and merely imaginary want of power was overcome by a medical manœuvre. It will be for the medical practitioner, when consulted on these distressing occurrences, either to do as Mr. Hunter did, cheat his patient into a proof of power, or give assurances that the feeling and fear are mere hallucinations resulting from morbid delicacy and apprehension.

Respecting nostalgia, or a vehement desire of revisiting the land of our nativity, we have already remarked upon the strangeness of its locality in the nosology. It is curious that the Swiss peasantry are more affected with this feeling than those of most other countries. Dr. Darwin, whose Zoonomia contains much of what is exceedingly interesting, mixed with a great deal which is extravagant and false, makes the following brief remarks on the Maladie de Pais, or nostalgia, with which we shall conclude the present section of the present article.

An unconquerable desire of returning to one's native country, frequent in long voyages, in which the patients become so insane as to throw themselves into the sea, mistaking it for green fields or meadows. The Swiss are said to be particularly liable to this disease, and when taken into foreign service frequently to desert from this cause, and especially after hearing or singing a particular tune, which was used in their village dances, in their native country, on which account the playing or singing this tune was forbid by the punishment of death.—*Swingerus.*

Dear is that shed to which his soul conforms,
And dear that hill which lifts him to the storms.

PART V.

APPENDIX TO THE NOSOLOGY.

431. 'On the subject of worms, acute hydrocephalus, calculary disorders, and cutaneous affections, the nosology and first lines of Cullen will be found defective; while vaccinia, angina pectoris, and tic douloureux, are affections in respect of name and especial investigation posterior to the time of our systematist.'

Of worms, it will be seen, we have already treated, by extracting from Dr. Hooper's Vade Mecum the section which he devotes to their consideration; in that extract will be found very many prescriptions for the best form of vermifuge; but we might perhaps have added, from another author, that, after all, the counteraction of the condition upon which worms depend is the great business to be aimed at; and this is to be effected by change of air, change of scene, change of diet, and whatever breaks in upon those habits with which a wormy tendency has associated itself.'

Of hydrocephalus we have also taken an opportunity of treating in the third class of diseases; although, upon any other principle than that of its being a scrofulous or lymphatic affection, its consideration would have been there misplaced; but the nosologist, we have again and again said, finds insuperable difficulties to contend with when he endeavours to make place, and name, and order, conform with his premises; and 'even an anatomical arrangement of morbid affection, would, under the present circumstances of our pathological knowledge, leave some of the most important disorders untouched by its embrace.'

On calculary, cardiac, and cutaneous ailments, we now proceed briefly to comment, leaving the more particular notice of them to the articles Urea, Skin, functions, diseases, and management of, and Physiology, in the alphabetical course of the present publication. On Vaccinia too, as demanding very particular consideration, we defer our remarks till the occurrence of the word in its alphabetical order.

432. *Calculus.* Stone and gravel.—Inflammatory affections of the kidneys and bladder have already been commented on; and the diseases which we are now to notice very often produce these. Indeed there is not a more frequent source of inflammation in some portion of the urinary organs than calculary concretions; on the other hand, however, it ought to be recollected, that the passing of a considerable concretion through the ureters is often productive of excruciating pain without any inflammation being excited. But we are now to turn our attention to the nature and composition, and modes of affection, and counteractives, of these concretions themselves; and we proceed to offer a remark or two on the peculiar symptoms of the stone and gravel:—

We may observe, in the first place, that the existence of calculus in the bladder, is for the most part accompanied by less derangement of the general health than the same quantity of local irritation engenders when produced by other causes. This mark of distinction is especially insisted on by Dr. Heberden, and with extreme propriety. Thus if we have bloody urine, if we have mucous discharges from the bladder, if we have difficulty and obstruction in the passage of the water, and pain about the back, testicles, and groin, as indications either of a diseased prostate, an irritation of the mucous membrane of the bladder, or from any other source than that of stone, we find always that the whole system sympathises much more than in stone with the local complaint. Thus we have wasting of the flesh and strength, hectic fever, disrelish for food, rigors, and such like attendants upon these states of disordered action; whereas in calculous pains and irritations the patients, during the intervals, are often as free from any signs and symptoms of disease, as if they were in the enjoyment of perfect health. A frequent mark of stone in the bladder is the discharge of urine tinged with blood, without any accompanying mucous or purulent admixture: this, again, is an unfrequent case in respect of other irritations, which, if they are sufficiently great to produce bloody urine, at the same time occasion also in a greater or minor degree muco-purulent discharges. The motion of a carriage or of horse-back exercise almost invariably excites or increases pain from stone in the bladder, which is by no means so common in respect of other irritations. Tenesmus or a frequent desire to discharge the contents of the lower bowel, most usually attends enlargements of the prostate gland in consequence of the immediate connexion of this gland as far as situation is concerned with the rectum; this tenesmus is not an invariable, nor even a very frequent, accompaniment of stone. Pain and difficulty in discharging the urine is a very usual mark of calculus, and so it is of other affections of the urinary organs, but in these last the pain is almost constantly perceived at the commencement; whereas in stone it is almost invariably during the discharge or just as the

micturation is concluded, that the obstruction and pain are most troublesome. It is to be recollected that the prostate gland itself is sometimes the seat of stone, as well as the subject of inflammation and schirrus, and in this case the diagnostic marks are somewhat more difficult still to trace. 'A decisive diagnostic,' says Dr. Marcet in his Treatise on Calculus, 'is still wanting of the presence of stones in the prostate. Some practitioners consider the circumstance of the uneasiness being much increased by riding in a carriage or on horse-back as the best discriminating symptom of a diseased prostate; but similar symptoms being often occasioned by stone in the bladder, they cannot alone lead to any positive conclusion. But I have heard of an instance, under the observation of Sir Astley Cooper, in which this pathological point was clearly decided by manual examination. A gentleman about twenty-one years of age became subject to a suppression of urine, for which Sir Astley was consulted. Upon passing a catheter, a grating sensation was felt at the neck of the bladder, and the finger being introduced into the rectum, some calculi could be felt moving in a cyst within the prostate, and a distinct clapping could be heard as their surfaces were pressed together. It was proposed that a small incision should be made through the rectum into the prostate, for the purpose of extracting the calculi, but the gentleman would not submit to the operation.' Into the further particulars of this case it would be carrying us beyond our province to enter; and we shall conclude by urging the necessity of minute attention to all the bearings and circumstances of the case, previously to the predication of an opinion on the existence or not of calculary concretions in the urinary bladder; and of the several species and varieties of these concretions we are now briefly to treat. The following is the division of these concretions which was proposed some time ago by Dr. Wollaston, who paid a most minute and scientific attention to this subject:—1. Scheelian uric, or lithic calculi, composed of uric oxide, or urate of ammonia. 2. Fusible calculi, which are formed principally of the phosphate of lime, and the triple phosphate of magnesia and ammonia. 3. Bone earth calculi, which are made up entirely of phosphate of lime: and these three let it be observed, especially the first or the lithic calculus, are by far the most common. The mulberry calculus is added in this arrangement, so named from its external appearance, which is principally composed of oxalate of lime. 'Urinary calculi,' says Dr. Monro, junr., 'may be divided into five classes; the first includes those composed of uric acid and urate of ammonia; the second such as consist of phosphate of lime and the phosphate of ammonia and magnesia; the third class consisting of oxalate of lime and silica; the fourth contains a proportion of urate of ammonia; and the fifth includes those calculi which are composed of cistic oxide. Besides the above substances,' Dr. Monro adds 'urea and animal matter enter into the composition of urinary calculi; the latter of which cements together the other ingredients. There are very few urinary calculi,' he further adds, 'which consist of only one ingredient.' Dr. Marcet observes in his Treatise, 'Upon the whole the different kinds of urinary calculi may be arranged under the following heads:—1. The lithic calculus. 2. The bone-earth calculus, principally consisting of phosphate of lime. 3. The ammoniaco-magnesia phosphate or calculus, in which this triple salt obviously prevails. 4. The fusible calculus, consisting of a mixture of the two former (more frequent). 5. The mulberry calculus, or oxalate of lime. 6. The cystic calculus, consisting of the substance called by Dr. Wollaston cystic oxide. 7. The alternating calculus or concretions, composed of two or more different species arranged in alternate layers. 8. The compound calculus, the ingredients of which are so intimately mixed as not to be separated without chemical analysis. 9. Calculus from the prostate gland.' The lithic calculus, the earthy phosphates, and the mulberry calculus, being by far the most usually found, we may just observe that the first is brown and smooth, and uniform, and generally of a flattened oval figure: the earthy phosphates are generally of a grayish-white and are less compact; the mulberry calculi are nearly black, and they are of a protuberant irregular shape.

Of the tests of each.—These we shall principally extract from Dr. Marcet. 'Take a fragment of the stone which you suppose to be formed of lithic acid, expose it to the flame of a blow-pipe, it will if thus constituted immediately blacken, emit a smoke of a strong characteristic odor, and be gradually consumed. Secondly pour upon the fragment in a glass vessel some caustic or pure alkali, and by the addition of heat it will be readily dissolved. Lastly, if to a small particle of lithic calculus, however impure, a drop of nitric acid be added, and heat applied, the lithic acid disappears.' The phosphate of lime calculus may be easily identified by first blacking before the flame of the blow-pipe, but soon afterwards becoming perfectly white, and not like the other exhibiting any appearance of fusion unless the most intense heat be applied. This calculus is readily soluble in muriatic acid. The ammoniaco-magnesia phosphate will have its ammoniacal portions disengaged by the heat of a blow-pipe, and the remaining phosphate of magnesia becomes opaque, and is capable of undergoing an imperfect fusion. This calculus is more readily soluble in dilute acids than even the phosphate of lime. The fusible calculus is easily distinguished when exposed to the flame of a blow-pipe, by melting, bubbling up, and running into globules of a pearly appearance. This likewise is readily dissolved by acids, and particularly by the dilute muriatic acid. The mulberry calculus is often abundantly distinguishable by its external appearance.' Its most obvious chemical character is to swell out when exposed to heat, and to expand into a kind of white efflorescence, which when brought into contact with paper stained with the juice of violets and slightly moistened, turns it green. The cystic oxide may be distinguished by its peculiar waxy appearance, and by its peculiar smell when heated, and the great solubility of its substance both in acids and in alkalies. Not

then to go any farther into the minutiæ of chemical composition by which these concretions are characterised, it is proper again to call attention to the leading distinctions of solution in an acid or an alkaline medium. Suppose it admitted, that, by administering a certain quantity of alkali in any form by the stomach, we could insure the arrival, so to say, of a definite quantity of that alkali to the kidneys and bladder, it might be concluded that were we prescribing for a mulberry calculus we should be doing no good, inasmuch as this is not acted upon by alkalies as just stated. But further, supposing that the offending matter which we wished to soften down or dissolve, to be made up principally of the alkaline phosphates, we should it has been said, in that case, not merely be throwing away our medicinals, and teazing our patients to no purpose, but we should be actually doing something worse, and positively furnishing the calculus already formed with a fresh pabulum for growth and increase: whereas, thirdly, if the concretion be (as it confessedly in the great majority of cases is), the lithic acid, alkaline solvents would then be proper and efficient.

With respect to the constitutional disposition or exciting causes which combine to effect these several concretions, we still remain much in the dark. It seems, indeed, still to be a disputed point, as in the case of diabetes, whether the altered affinities which are brought into play, in order to evolve these depositions from the urine, commence primarily in the stomach, or are the result of some particular undefined action in the urinary organs, or in the circulation; or whether the stomach affections which are so commonly attendant upon renal derangement be consequent upon, or the causes of such derangement. And, in regard to the exteric cause immediately productive of them, nothing certain has been ascertained. The drinking of hard water has been accused of having an influence upon their formation, but, beside that these concretions are widely different from any compositions of the several mineral or earthy springs, we find in fact that individuals are quite as subject to them who live constantly upon soft, as those who all their lives drink what are termed hard waters. Calculous affections are hardly known in the tropical climates, where the skin is kept in much more activity than in colder regions, and this has led to the preventive indication of attending to the external surface and keeping up cutaneous discharges. Of the prevention, however, of these concretions we know nothing more (nay, perhaps this is hardly ascertained) than that substances taken into the stomach, which are calculated to derange its functions, and thus to engender acidities, are calculated in the same measure to encourage calculous deposits in those who are either by nature, or by some undetected causes, obnoxious to such maladies. And with respect to the remedies there is much doubt in the minds of several of the medical profession, whether we are possessed of any specific or radical counteractives, even in the present state of our advanced knowledge in reference to their chemical composition and solvents. On this head, however, there may be some scepticism arising out of indolence; and it certainly does appear wrong to abandon calculous patients to their fate, merely because medicines have often proved inefficient or even worse than useless. The question of the efficacy of calculous solvents, when taken into the stomach, would appear nearly to be resolvable by the determination of another problem, namely, whether it be possible for alkaline, acid, or any other substances to pass unchanged to the urinary organs? Now, it is a remarkable fact in the animal economy that certain substances shall be taken into the stomach, shall circulate with the blood in a kind of latent state, and shall afterwards by secretory action, especially by the secretory action of the kidneys be made to develope themselves. This takes place certainly with regard to alkalies, which have been actually found in the urine by direct experiment, after a long course of alkaline medicines has been taken into the stomach, and the probability is that the same effect is operated upon the urine by the reception into the stomach of the mineral acids. The quantity is allowably very small that is capable of being conveyed in either case, and the solvent operation upon already formed, hard, compact, calculi, at the very least, extremely problematical; still, however, nascent concretions may be prevented from arising to any height by such medicinals, and their obvious diuretic effects, especially of the alkalies when it is proper to administer them, may in some measure serve mechanically to force away small deposits of calculous matter, and likewise tend to change the secretory action of the kidney itself. A difficulty has been suggested respecting the agency of alkalies as solvents of lithic concretions, upon the ground that the carbonated or mild alkalies have been thought equally efficacious as medicinals with the pure or caustic alkalies, whereas these substances in this their mild state possess out of the body much less solvent property. This objection, however, has been answered by stating that the carbonic acid of the mild alkalies may be expelled in the first passages, and that thus the medicine is brought to the same condition of efficiency as had it been taken uncarbonated or pure. The aereated alkalies may also be taken in much larger quantities than the caustic. The principle then being admitted that both the alkalies and mineral acids may have a remedial operation upon calculous complaints, when judiciously and appropriately employed, it becomes a further question what is the best form for the administration of either. It would appear in general best to change the alkaline carbonates for each other at times, and at other times to administer the soda or the potass in alternation, so as to obviate their possible deleterious effects upon the stomach, and prevent the disposition to inefficacy, which habit occasionally engenders. Some little time since much talk was occasioned by a proposal for a substitution of magnesia in place of the medicines more purely and properly alkaline. This substitution was first proposed by Sir Everard Home, and the grounds upon which its superiority was claimed are its being less offensive to the stomach than the alkalies, and its aperient tendency when meeting with acid in the stomach;

and these advantages it certainly possesses, but it does not seem to be able to communicate to the urine alkaline properties quite in so great a degree as the alkalies; and there have been cases in which a protracted use of magnesia has occasioned large concreted masses in the intestines, which have proved very troublesome, and even have been attended with fatal effects. It has been thought that magnesia when administered without any knowledge of the constituents of the calculus, for which it is given, may prove actually deleterious, when administered in cases of the fusible concretions, by adding, as far as its substance and principle is capable of being conveyed, to the actual mass of the body, to lessen which it had been exhibited; but the purgative and alterative action of the medicinal upon the primæ viæ may serve to counteract this effect. It is in this last mentioned calculus, especially, that the muriatic acid has appeared to be attended with so much benefit. In this species, says a modern author, which I am inclined to think is much more common than is usually suspected, the benefit obtained from an acid solvent is much more rapid than could be expected from the usual effect of reputed solvents in other species of calculus. Six drops of the muriatic acid, in water, were given to five patients and repeated every two hours. Two of them received immediate relief not only from all the distress which accompanies a common attack of gravel (as it is called) but also from a most painful restlessness, an excessive thirst, and a continued tendency to fainting, which symptoms seem in a peculiar way to attend this species of calculus. Two others of them experienced a relief as complete, though not quite so expeditious: and the fifth passed considerable quantities of the sand, loosely cemented together during the whole time he was taking the acid, under my eye; whether he was ultimately cured I am unable to say.' The above observations, it will readily be seen, apply to the uric and to the triple phosphate calculi. It will be recollected we stated that the mulberry, the next most usual form of calculus, is not acted on with facility either by acids or alkalies, and that consequently no principle of treatment hitherto detected can be brought to apply to it. Dr. Wollaston has observed 'that as this mulberry calculus consists chiefly of the oxalate of lime, and as the acid of sugar is known to abound naturally in a species of oxalis, it is probable it may be contained also in other vegetables and fruits; and therefore it may be assumed that the secretion in question would be modified by avoiding such vegetable aliments as may be suspected of yielding that acid.' The alkalies, says Dr. Marcet, may be used with advantage in this, as in the other species of calculi, to allay irritation; and they may also be possibly beneficial by combining with the oxalic acid in the primæ viæ, and preventing those displays of affinities that cause it to unite with the lime. Yet a still more beneficial effect is likely to be obtained from the use of the mineral acids which have the power of dissolving the oxalate of lime in its nascent state, and may therefore, if it do not prevent its formation, at least serve to assist its passage and ultimate expulsion from the system in a state of solution.' Upon the whole, however, it must be admitted that the alkaline principle of lithontriptic agency is that alone upon which much dependence is to be placed; and that as stomachic and diuretic, and in this way preventive, it is questionable whether the objections lie against their use to the extent that we might chemically conclude even in those cases where the concretion is not formed mainly of lithic acid; then again it is to be taken into account that a very large majority indeed are so composed.

Reviewing all that has been laid before the reader, says Dr. Wilson Philip, in a paper he published on this subject, I cannot help thinking that we have reason to believe that gravel generally originates in a precipitation of lithic acid in the kidneys, in consequence of a greater than usual quantity of another acid, generated chiefly in the primæ viæ, passing by these organs; and that the best plan of prevention is to correct the tendency in the primæ viæ to form this acid; to support by means which invigorate the powers of circulation the action of the skin by which in health any superabundance of acid is thrown off; and when we find that notwithstanding such measures too much acid still passes off by the kidneys to correct it by antacids before it enters the circulating fluids. The conclusions too of Dr. Prout are pretty nearly the same.

433. *Cardiac Disorders.*—On affections of the heart we feel that we cannot give an account at once more succinct and satisfactory, than by extracting the remarks of Dr. Gregory, which we therefore venture upon the liberty of doing, again reminding the reader that under the word STETHOSCOPE in the Encyclopædia we shall enter into an enquiry respecting the extent to which the different kinds of auscultation may be made to apply in the detection of structural and organic diseases within the thorax.

'To a disease exhibiting many uniform and characteristic symptoms, and usually considered as depending on some chronic derangement in the heart, either functional or structural, Dr. Heberden in 1768 gave the name of angina pectoris. Dr. Parry of Bath has treated of it fully, under the title of syncope anginosa. In Dr. Cullen's nosology it has received no place, although it might readily have found one next to asthma, to which, in many of its characters, it bears a strong analogy. Modern writers have added but little to the observations of the distinguished author who first described this disease.

Angina pectoris consists of repeated paroxysms of violent pain or uneasiness about the chest, occurring principally when the patient is walking up hill, or soon after eating. The feeling of pain is so acute as to make him instantly stand still and even to give the apprehension of immediate death; it is referred to the sternum, a little inclined to the left side; from this point it shoots across the breast to the left arm, and appears to terminate at the elbow. In some cases it shoots to the right breast, and passes down the right arm in a similar manner. At first the paroxysms do not last more than a few minutes, and occur only at long intervals. Gradually they lengthen and recur too with increased frequency; being brought on, not only when the patient is walking

but when sitting or lying down, and by the slightest bodily exertions, or even anxiety of mind. The duration of the paroxysms has been, in some very severe cases, protracted to half an hour or more, the face and extremities becoming pale and bathed in a cold sweat, and the patient, for a while perhaps, deprived of the power of sense and voluntary motion.

The character of the pulse during the fit is apparently subject to considerable variety. Dr. Heberden found it sometimes, though far from uniformly, affected. Dr. Fothergill reports, that in his cases it was commonly intermitting or irregular. There is always some difficulty of breathing, or at least a distressing sense of suffocation, present at the same time, and in the advanced periods of the disease the stomach becomes unusually irritable. Angina pectoris has been known to last for many years; yet the prognosis is very unfavorable. In the larger proportion of cases it proves fatal suddenly, from causes which will soon come under consideration. The diagnosis has often been looked upon as a matter of considerable difficulty, but I think without sufficient reason. Angina pectoris derives its character from symptoms present during life, and not from any appearances found after death; and, if the former are observed, the disease is at once entitled to such a denomination.

It has indeed been attempted by some pathologists to attach the peculiar symptoms of angina pectoris to an ossified state of the coronary vessels of the heart, but this is taking too confined a view of the subject. More enlarged experience will show that this state of disease is connected with several kinds of structural derangement within the thorax, though certainly this is the most frequent of them all; but, to prove that the restricted notions of the disease entertained by Dr. Parry and others are not correct, it is sufficient to state, that in many cases (and very remarkably in that described by Mr. H. Watson) a most extensive ossification of the coronary arteries existed without giving rise to a single symptom of thoracic disease. Dr. Latham, in an interesting communication to the London College of Physicians, has described two cases of enlarged liver, in which all the genuine symptoms of angina pectoris were observed. Both patients died suddenly.

This disease, lastly, has proved fatal where the most accurate anatomists have failed in detecting any morbid alteration of structure; and upon the whole, therefore, we must conclude, that angina pectoris is, in strict pathology, a chronic functional derangement of the thoracic organs, frequently associated with, but not directly depending upon, disorganisation of the heart.

The objects of medical treatment in this affection are limited to affording some degree of relief while the paroxysm is actually present, and to the avoiding as far as possible all those circumstances which occasion its renewal. With a view to immediate relief we have recourse to a small blood-letting, carminative draughts, and opiates. The more important object, of preventing the gradual inroads of the disease upon the constitution, is to be attempted by strict attention to diet and regimen, the regular use of aromatic laxatives, and the insertion of an issue or seton. All practitioners agree in the benefit which is derived from using the lightest and most digestible food, with perfect abstinence from fermented and spirituous liquors. Even in the latter periods of a protracted paroxysm, when the prostration of strength appears extreme, we are to hesitate in giving wine and cordials. The heart is here oppressed, not weakened.

Any thing that hurries the circulation is sufficient to bring on a paroxysm. The patient should therefore be cautioned to keep his mind quiet, and to refrain from all severe exercise. Flatus in the stomach and a torpid state of the bowels are so commonly found accompanying this disease, and either inducing or aggravating paroxysms of it, that the practitioner will do well to obviate, by the use of aromatics, bitters, and laxatives, any irregularity in the action of the chylopoietic viscera, which he may observe. Where sleep is interrupted, he may with propriety exhibit some narcotic—the extract of hyoscyamus for instance, or opium. Dr. Heberden says that he has known opiates given at night, in many instances, prevent the accession of a paroxysm.

The symptoms occasioned by the several kinds of structural disease of the heart and great vessels have been closely investigated by modern pathologists. Enquiries however have rather tended to show that they are obscure, than to establish their uniformity; and, as the whole subject is one of curiosity more than of practical interest, I shall be very brief in my notices concerning it.

1. The simplest, and one of the most frequent structural derangements of the heart, is dilatation, either general or partial, of its cavities. This sometimes takes place without any increase in the muscular parietes of that organ. At other times the heart is enlarged by an addition of solid substance, cellular and muscular; its cavities remaining little, if at all, more capacious than usual. The symptoms vary according to the nature of the enlargement which the heart undergoes. Simple dilatation of its cavities is attended with a sense of oppression about the chest, a full, slow, soft, or sometimes even an imperceptible pulse. Persons have lived in this state for many years. The disease goes on, in almost all cases, to produce dropsy, and most remarkably dropsy of the pericardium, and consequently urgent dyspnœa. In some instances chronic inflammation of the pericardium supervenes a short time before death, when the character of the symptoms very essentially changes. Nothing is known regarding the causes of simple dilatation of the heart. It has been observed in young persons, without any disease of the valves, or other mechanical impediment to the transmission of blood.

2. Where the heart is enlarged by increase of its muscular parietes the symptoms are nearly the same with those formerly described as attending chronic inflammation of the pericardium. There is a constant sense of struggling in the thorax, with inexpressible anxiety referred to the heart. The pulse is quick, hard, and jarring, and,

when the hand is applied to the chest, the stroke of the heart seems restrained, and is succeeded by a kind of thrilling. Such cases are truly deplorable, and much more formidable than those of simple dilatation. The bodily strength becomes rapidly exhausted, the faculties of the mind are overpowered, and the patient is debarred from every source of enjoyment. Dropsy commonly supervenes in this as in the former case. The solid enlargement of the heart is believed to be always dependent upon some mechanical impediment to the free transmission of the blood, and is therefore often found united to a diseased state of the valves. This suggests the pathological principle (warranted certainly in many cases), that, in proportion to the resistance offered to the passage of the blood, the circulating powers have their strength augmented.

3. Much importance has always been attached by pathologists to the changes of structure which the valves of the heart and large arteries so frequently undergo, and to the symptoms thereby occasioned. That in many cases diseased valves are the direct cause of various marks of obstructed circulation there can be no doubt, but it is not to be forgotten that they are often found where no symptoms had led to the suspicion of them. It is, I believe, quite impossible to ascertain with any degree of precision during life the existence of diseased valves, as separate from every other variety of disorganisation of the heart. Still more hopeless is any attempt to determine what valve or set of valves are affected. The general symptoms of obstructed circulation, by which we are led to form a plausible conjecture as to the existence of ossified valves, are, according to Dr. Baillie, frequent palpitations, a difficulty of breathing, a weak and often irregular pulse, and in some cases a disposition to fainting. To these symptoms other authors have added, and I believe justly, hæmorrhage from the lungs and dropsy.

4. Aneurism of the thoracic aorta is a frequent and most distressing state of disease. It can never be distinguished with any degree of certainty until it has attained to such a size that a tumor begins to be formed externally, accompanied with a strong pulsation. Dr. Baillie cautions us against supposing that strong pulsation in the chest indicates necessarily the formation of aneurism. It is generally attended with more or less of pain in the aneurismal tumor, shooting to the arm of the same side; and, in proportion to the advances of the disease, the breathing becomes disturbed. It sometimes proves fatal suddenly by the bursting of the sac, but in many cases the patient is destroyed more gradually by interruption to the respiration.

The unpleasant symptoms occasioned by aneurism of the aorta admit of very essential relief, and perhaps even the growth of the tumor is sometimes checked, by medicine. Repeated leeches to the chest have proved serviceable in many cases, and the application of cold to the tumor has been occasionally productive of advantage. Digitalis unquestionably possesses a very considerable power in moderating the urgent symptoms, and, if to the occasional employment of this drug is added a strict attention to diet and regimen, the patient may often pass the remainder of his days with tolerable ease.

5. Congenital malformations of the heart and large blood-vessels are of various kinds, and they have been ably described by Dr. Farre, to whose work I beg to refer for the anatomical peculiarities of the several cases. They all agree in one result—the intermixture of venous with arterial blood throughout the body. It is certainly a curious fact, that life should be compatible with such a state of the circulating system; yet it is so; and persons have been known to live for many years with it, and even ultimately to die of a disease unconnected with such a deviation from ordinary structure. The great source of mischief and danger, as Dr. Farre has pointed out, is not the mere mingling of black and red blood, but the difficulty with which the circulation is generally carried on by a malformed heart. This is connected, in many cases, with the comparatively small size of the pulmonary artery, the consequence of which is, that the full proportion of blood is not circulated through the lungs.

The principal symptom of malformed heart is a permanent blue color of the skin; from which circumstance the term blue disease has commonly been applied to these cases. The other symptoms to which it gives rise are general weakness of the whole frame, permanent or spasmodic dyspnœa, palpitation, an irregular, weak, or intermittent pulse, and in some cases coldness of the skin, and emaciation. Persons who have malformed hearts are liable to hæmorrhages, dropsical effusions, attacks of syncope or of epilepsy, and occasionally to the unequivocal symptoms of oppressed brain.'

434. *Cutaneous diseases.*—The term cutaneous, as applicable to a distinct series of morbid affections, wants something to make it very precise and definite. Certain it is, that, in the majority of those complaints which are regarded as diseases of the skin, this part of the body appears to be the principal seat of the deranged action, and the constitutional affections which are concomitant upon these external irritations seem often to be excited merely by the violence of the cutaneous derangement. When, however, these superficial marks of disease arise, as they often do, in consequence of the reception into the body of a specific morbid poison, it must of course be concluded that some sort of constitutional or general ailment precedes the local expression of the disease, upon which the cognomen is founded. This indeed is most obviously and decidedly the case in reference to the action of some of these poisons, as in syphilis for instance, in which, connected with the external signs of disease, we have internal pains and other marks denoting internal and systematic disturbance. Indeed the vulgar creed is, with regard to all affections of the skin, that they are merely indices or displays of constitutional states, and hence the notion of noxious humors and foul blood. Into this notion, we have already hinted, that some pathologists have too readily given, by the institution of an order of distempers under the denomination of cachexia, which, founded upon the Greek word κακος, signifies a bad habit of body; and, previously to the laws of secretion and excretion

having been properly recognised, it was conceived, both by the profession and by persons generally, that the marks on the skin were a sort of elimination, as it were, of this morbific matter, which, till it appeared upon the surface, was in some way or other floating about in the humors of the body. Now, that this notion is not only vague but actually incorrect, is shown by the fact that the most extensive affections shall at times exist in the exterior of the body, while the fluids of the body are free from any similar taint. It is therefore not distempered humors, but a certain species of deranged action, the actual essence of which is altogether inexplicable, which gives origin to the derangements in question. To this principle there may seem to be some exception in scorbutic and some other morbid states, where the blood appears to partake of the distemper which at the time pervades the frame; but even in these cases there is for the most part merely a want of proper constitution and crasis of the blood, rather than any chemical impregnation of a specific nature; and there are several remedial influences upon these disordered habits that, by curing the malady, alter the constitution of the fluids, which it is impossible for them to have effected by any immediate or direct operation of a chemical nature. Of mental influences as remedial in scurvy, we have already spoken. It is then, to say the least, extremely questionable whether those long processes of medicine, the fashion of which is indeed a good deal going by, that are instituted upon the notion of effecting an alteration in the mass of circulating fluids, have any more than an imaginary operation. Although, however, we must abandon the notion as untenable which hinges upon the supposition of these chemical changes in the fluids, we are compelled by observation to admit on the other hand, that there is in a great number of cutaneous irritations such an intimate connexion with constitutional and internal changes, that to repel precipitately the one is often to give rise to another morbid action. Thus let some species of skin eruption be suddenly dried up, by the employment of external astringent or repellent medicinals, and, if there be tendency in the habit to asthmatic affection, a difficulty of breathing and other indications of pulmonary ailment will often immediately establish themselves, although if you draw blood from the patient under either circumstance of affection of the skin or the chest, you will not find it impregnated with any material of a morbific kind. Cutaneous affections then are rather disordered actions than evidences of depraved fluids—this disordered action sometimes pervading the internal organisation ab origine, at other times affecting the interior merely by the violence or repression of the local irritation, and occasionally being constituted solely by a depraved action in the surface itself, the internal organs not being affected either primarily or sympathetically. Whether are cutaneous distempers susceptible of classification? To this question we should be disposed to reply in the negative, notwithstanding the recent exertions to embody and arrange this varying expression of disease. In the classes of Dr. Willan and Bateman, we find at the very outset an obvious error, inasmuch as the epithet cutaneous is made to apply both to those affections the exclusive residence of which is the skin, and also to such as are preceded by internal irritations of an obvious and active nature, and of which, as in small pox, the state of the body's surface is but one link in the chain of disordered actions. Again, the evanescent and fugacious habits of these cutaneous irritations is extremely hostile to any definite arrangement of them. The disease, for example, to which we have just referred, is, in reference to its external characters, a different affection on one day from what it is on another. We are, thirdly, so little aware of the precise nature of the morbid poison which gives rise to most of the skin diseases, that it is impossible to trace and mark their effects, but by the most arbitrary assumptions of identity; and it may be questioned, whether the descriptions of the ancients, either in cutaneous or any other disorders, are sufficiently distinct and explicit, to enable us to apply them to modern maladies, such certainly is not the case with the order of diseases to which we are now adverting; their deficiency in intelligibly notifying by actual specification these diseases being a matter of notoriety. 'Disorders of the skin,' says Heberden, 'have been variously recognised and named by the ancient writers on medicine; the respective names which they attached to them are, however, not easily ascertained in the present day, nor does it appear of much consequence to aim at ascertaining them; and the division of these affections into kinds and species, which formerly obtained, is now pretty generally discarded or neglected. It is customary to name these anomalous and nameless affections scorbutic, but still without any sufficient reason.' 'Of proper scurvy,' he continues, 'I have nothing to say; nor of the real leprosy, since the former being exceedingly rare in cities, and the latter hardly known in England. I have never had an opportunity of examining them; and with the exception of these two, the itch, the herpes, and the tinea capitis, or scald-head, seem to be the only cutaneous affections about which medical opinion appears to be unanimous as it regards names and descriptions.' Other authors make a division of the herpetic eruptions into two species, viz. the true herpes and the impetigo or ring-worm. 'In the herpetic eruption,' says Dr. Monro, 'there is a small vesicle with a thin scale at the top, and the base is surrounded with erysipelatous inflammation. Sometimes herpes appears under the form of flat patches, which are covered by small scales. This form of the disease is very common on the scalp. When the scale falls off the skin below is generally nearly sound, though somewhat discolored. The herpes appears also in the form of very small vesicles, like millet-seeds; which appear in clusters, and are filled by a viscid lymph, which exuding, forms rough yellow scabs, and when the scab falls off it is apt to be renewed. This kind of herpes sometimes attacks the throat. Another kind of herpes has been called the herpes exedens; for it destroys the skin, sometimes it spreads along the whole surface, but in other cases penetrates deep.' When speaking of the ring-worm, which Heberden includes under the

general name of herpes, Dr. Monro says, 'In this disease there are a number of small red pimples, filled by a thin acrid fluid, which are disposed in a circular manner. This disease in some constitutions becomes of an inveterate nature, and is diffused over the whole body, like the lepra.' The lepra is described by this author as a disease in which there are a number of copper-colored spots over the whole body; these are in a great measure insensible. The skin, when the disease has made progress, becomes rough and scaly, or is covered by warts; and fœtid sores sometimes break out in different parts of the body.' Tinca, herpes, psora, are Heberden's three distinct diseases of the skin. Sibbens, syphilis, lepra, elephantiasis, frambæsia, acne, are talked of by others, and we shall proceed to offer a few observations under each of the above heads:—Tinea, or as Dr. Willan calls it, porrigo, or scald-head, is formed by a peculiar chronic inflammation of the skin of the head, which prevents the proper growth of the hair, and thereby occasions it to fall off. The matter which is secreted in this complaint is capable of producing itself in the head of another individual by being applied to it, but the disease is not probably otherwise contagious. It appears, however, capable of being engendered by uncleanliness and unwholesome food. It is not for the most part difficult to cure. The hair ought to be cut away close from every part where the eruption makes its appearance, and the unguentum picis applied over the whole of the ulcerated surface. When the unguentum picis fails, the citrin ointment may be used. the ung. hydrarg. nitrat. of the pharmacopæia; this is for the most part too powerful of itself, and requires to be mixed with an equal quantity of the cetaceous ointment. The disorder usually lasts for a month or two or more. When the external applications seem to fail, or not to act with their usual power, the sulphuric acid taken internally will often prove exceedingly useful in promoting cutaneous absorption. It is scarcely necessary to say that where poverty of diet has been either wholly or partially the cause of the complaint this must be changed for nutritive and wholesome food. The bowels must be kept regular, and even purging in some cases is advisable, especially when, with the retrocession of the eruption, the glands of the neck seem disposed to swell, or the general health affected.

Herpes breaks out in different parts of the body, and is sometimes exceedingly painful and obstinate. Its local remedies are the various preparations of mercury, with which the internal use of this medicine may be occasionally combined. Warm bathing is sometimes useful by promoting a regularity in the cutaneous excretion. The true herpetic eruption, according to Willan and Bateman, is a vesicular disease (see the heads of classification at the end of the present section). The shingles is in their scheme a true herpes (herpes zoster). This disorder usually occupies some part of the body rather than the extremities, it consists of little vesicles or bladders on an inflamed base; and these extend often for some inches in length, appearing like little clusters of minute vesicles on a red pimple. It is attended with a good deal of irritation at times, when the patch of eruptions is large, but does not require any medicinal beyond that of keeping the bowels gently open; it lasts from a week to a fortnight. Respecting the vulgar notion of its fatality, should it complete the circle of the body, we need not say any thing.

The herpetic ring-worm of the head is distinguished from the porrigo or scald head. Of the psora, or itch, there seem to be at least two or three varieties; and hence the discordant accounts which we meet with in authors, on the question whether this disease is constituted of animalcula? 'The animalcula,' says a modern author, 'which are seen in the pustules of itch are the effect, not the cause, of these pustules, as all other stagnating fluids abound with them.' But Dr. Heberden tell us that he has never been able to discover these same insects in itch either as a cause or consequence of the distemper, and that other physicians have told him the same, although they have brought to the investigation microscopes of large power. Dr. Bateman imagines that the breeding of these animalcula in a scabious skin. is a rare and casual circumstance, and that the contagious property of itch consists in the fluid, and not in the transference of insects.' Dr. Adams, however, proposes a different method of reconciling these discordances, and concludes, 'that an eruptive disease, independent of the itch, is excited by an insect, called in Ireland the flesh-worm, in France the cyron, in Portugal the oucas; once well known in England by the name of wheal worm, and still sometimes occurring. That the disease which it excites from some resemblance, from situation, and from yielding to the same remedies, may be mistaken for itch; but that the insect has never been discovered in true itch, when searched for in the most marked cases.' Whether the itch is capable of being engendered by bad air, unwholesome diet, or deficient cleanliness, is another question about which there has been some diversity of opinion. There is, however, one kind of itch which has been named scabies cachectica, evidently the product of these sources, independent of contagion, and indeed, according to Dr. Adams, incapable of being propagated as a contagious distemper. Dr. Adams names this affection herpes pauperum. 'It occurs,' he says, 'in confined nurseries, if change of air is not introduced, but without extending to other parts of the house.' 'I have seen it,' he continues, 'in two or three misguided youths, who have returned to their parents after a temporary absence in the lowest order of society; in these instances it has never been communicated to the rest of the family. The more usual form, however, in which the itch makes it appearance is in the shape of small eruptions, which have for the most part little watery heads; and at other times, especially after a long continuance of the disease, these eminences become pustular, and run into one another. In this latter case the margins are slightly inflamed as in small pox. The fingers, wrists, waist, and hams, are the principal seats of these eruptions, which, however, often come eventually to extend themselves over the whole of the body. The itch is one of those affections

of the skin which may be, for the most part, to say the least, repelled with impunity; and most unquestionably the remedy of greatest efficacy in effecting this repulsion is sulphur. When this is objectionable, the several preparations of mercury may be tried, of which the white precipitate ointment is the most cleanly, and perhaps equally efficacious with any other. The internal use of sulphuric acid is often, in long-continued and inveterate cases, of conspicuous and abundant service. This has been said rather to apply to the pustular itch, and the liquor arsenicalis in doses of five or six drops, three times a day, to be more applicable to the herpetic or diffused psora. The white hellebore was formerly much in use in cases of scabies, but it is at present not much employed. Dr. Heberden concludes his chapter on scabies with the following observations:—'There are some contagious diseases, such as the small pox and measles, which only affect the system once in the course of life; others, such as the scarlet fever and the hooping-cough sometimes, although rarely, recur a second time. Some depend for their production upon the combination of certain external and internal causes, as in the examples of dysentery, camp-fever, and the plague Psora, however, and the lues venerea may always be produced by the application of their peculiar exciting causes. It is therefore to be regarded as a beneficent design in providence to have furnished mankind with specifics against both these poisons, viz. sulphur for the one, and mercury for the other; for had not that been the case the extension of the two complaints might have proved unlimited and almost universal.'

Respecting sibbens, opinion by no means appears to be unanimous; by some authors it is conceived to be a modification of the morbid poison which produces the frambæsia, or yaws; by others it is imagined to be the form in which the venereal disease first made its appearance. In the chapter in Celsus de obscænarum partium vitiis, there are several descriptions, which correspond more with the symptoms of disease called by the moderns sibbens, than they do with the true lues venerea. The following extract respecting this affection is from a work of professor Frank of Vienna:—'In 1800 a disease appeared in Dalmatia, which had the character of syphilis, but was rather considered a kind of lepra, as it was communicated not only by sexual intercourse, but also by every kind of intimate connexion. Several thousand persons were already affected, when Dr. Cambieri, district physician at Fiume, pronounced the disease, which was called by the natives scherlievo, a venereal affection, and the same with the sibbens in Scotland. In consequence of which the malady in question was not only treated with corrosive sublimate, but also its further propagation completely checked, by the erection of hospitals, and the adoption of other regulations, that in the course of three years it was almost exterminated. On this occasion Dr. Cambieri suggested the opinion that the sibbens, or the scherlievo, was the original form of the venereal disease, as it first appeared in Europe. For it is well known that it existed long before it was supposed that it communicated itself by sexual intercourse. Even the rapidity of its diffusion over all Europe, renders it probable that this was not the only way in which syphilis was then propagated.' Dr. Adams supposes that sibbens and syphilis are different diseases, although the former resembles the latter more than any other with which we are acquainted. 'The venereal ulcer,' says Dr. A., 'is attended with callous edge and base, and sibbens consists only of the clear phagadenic ulcer. The secondary local symptoms differ also; the venereal retaining longer its copper appearance, and afterwards becoming more elevated, retaining more of the color of the skin; and the scab when formed being more scaly. In sibbens the appearance is very rarely pustular, and I should conceive the pus still less in quantity than in syphilis. There is nearly the same difference between this and the venereal scab, as between the cow-pock and small-pox scabs. Lastly, it is now universally admitted, that sibbens never attacks the bones, but by spreading from the soft parts, and that it yields earlier to mercury than syphilis. This disease was a few years since exceedingly prevalent in the western parts of Scotland; but it appears to be at present on the decline, both with regard to severity and frequency of occurrence. Frambœsia, or the yaws, is a disease very common in the West India islands, and supposed generally to have been imported from Africa. Dr. Adams supposes that the leprosy of the Jews, described in Leviticus, was rather this disease (the yaws) than either the Arabian leprosy or the lepra Græcorum, and there appear some grounds for the supposition. The following is the description of this disease which is given by Dr. Thomas, who informs us that he has several times witnessed it: 'For the most part the patient complains of head-ache, loss of appetite, and pains in the back and loins, which are rather exasperated towards the evening. When these symptoms have continued for some days, they are followed by an eruption of pustules, more or less numerous, which appear in various parts of the body, but especially upon the forehead, face, neck, arm-pits, groins, pudenda, and round the anus. The eruption of these pustules is not completed over the whole body at one time. At their first appearance they are not larger than a pin's head, but gradually increase until they attain the size of a sixpence, or even of a shilling. The pustules are filled with an opaque whitish fluid, and, when they burst, a thick viscid matter is discharged, which forms a foul dense crust or scab on the surface. From the larger kinds of pustules there frequently arise red fungous excrescences of various magnitudes, from the size of a pea to that of a large mulberry. These fungi have but a small degree of sensibility: they never suppurate kindly, but discharge a sordid gelatinous fluid, which forms an ugly scab round the edges of the excrescence. When these eruptions appear upon any part of the body covered with hair, the color of this is gradually changed from black to white.'

The few words which we have to say on syphilis are merely in reference to the disorder as a cutaneous affection. The copper appear-

ance of the cutaneous eruptions in the lues venerea is their principal characteristic; they are not so phagadenic as some other ulcerations of the skin, but they appear more stationary, and are rather disposed to rise from the surface than to spread. The scurf or scab which forms over the true venereal ulcer is remarkable; and it is a very frequent occurrence to find the throat affected in conjunction with the cutaneous eruptions. When indeed this is the case, there is for the most part but little room to doubt respecting the actual nature of the disease; and, with regard to the appearance which a venereal throat assumes, it may be observed that there is a dead foul coppery kind of character in it, which, to a person who has once seen it, can seldom be mistaken a second time. One author has said that a venereal ulcer in the throat gives the appearance as if a portion of its substance was dug out, and this is not an unapt description of the appearance which it takes on. If not arrested, too, the palate and uvula come in time to be affected, so as to occasion a hoarseness in the voice. But, as we have just said, it is not within our intention to trace the progress of the venereal disease through its various stages and degrees; we shall content ourselves with merely introducing a caution against that tendency, which has become perhaps rather too determinate, to doubt the syphilitic character of actual syphilitic eruptions, and thus to forego too long the use of the only decided antidote hitherto discovered to the poison.

On the subject of lepra and elephantiasis the greatest diversity of sentiment has prevailed; and the discordant opinions in reference to these particulars do not seem as yet to be entirely econciled. In the writings of Aretæus we have very eloquent description of the disease, termed by this author elephantiasis, which commences with a description of the elephant, to which he compares the affection, or rather the subject of it. In the course of this description Aretæus acquaints us that the skin of the individual who is the subject of the affection becomes thickened and scaly, tumors and spots of various kinds break out in the upper parts of the body, the body itself becomes emaciated, notwithstanding which the face and the lower limbs swell, and, when the disease is inveterate, both the toes and the fingers become buried in tumefactions. Such is the elephantiasis of Aretæus, with which a more modern disease has lately been confounded, named by some the Barbadoes distemper. In this last disease one or both of the lower limbs is swelled to an enormous size, and the patient is sometimes free from any cuticular affection independent of this. That these two affections are distinct does not seem to admit of any doubt, but much controversy has arisen respecting the identity of the ancient elephantiasis and the lepra, described by the Arabian writers, of which Avicenna in particular speaks, 'quasi cancrum communem corpori.' Dr. Adams contends for the sameness of these two distempers, and he makes a division of the distempers in question into the Arabian or Syrian leprosy, or elephantiasis of the Greeks, the true lepra Græcorum and the Barbadoes leg. The leprosy of the Jews, we have already said, this author imagines may have been what is now called the yaws, and there is certainly a considerable correspondence in the delineated features of these two last diseases. The leprosy, of which we hear so much in the New Testament, is conceived to be the elephantiasis of the ancients, which, says Dr. A., is a chronic disease unattended with fever, and appears on most parts of the body in distinct tubercles. The scales which characterise this affection never appear but in the advanced stage of the disease, and are then only partial, while the lepra Græcorum is distinguishable by the scales being coeval with, and as general as the disease. In the one affection the elephantiasis, or Syrian leprosy, the disorder prevents the evolution of the genitals; in the lepra Græcorum, on the contrary, physical and sensual desires are extremely ardent and ungovernable. M. Sonini, in his travels through Egypt, informs us, that the subjects of leprosy are remarkable in this particular; and he mentions an instance of a leper, on the very night of his death, being hurried away even several times by the warmth of his passions. 'He further tells us, he has noticed in Canea, in the island of Candia, great numbers of lepers, both men and women, banished without the gates of the city in miserable hovels, where they abandoned themselves to the greatest excesses of voluptuous irritation. They were sometimes to be seen satisfying their disgusting and impetuous lusts in open day, by the side of the roads leading to the towns near which they lived.' Aretæus mentions this peculiarity in the elephantiasis, but Dr. Adams conceives that this feature is described by the Greek writer merely upon hearsay authority; and indeed, by his own confession, his description is taken in part from the relations of others. The true elephantiasis we are told by Adams is not contagious, but it is constitutional and incurable; and, from this last particularity in the distemper, he infers the difference between the lepra Græcorum and the lepers of the New Testament, upholding his opinion that these last were instances of the elephantiasis, and not lepra. 'That this disease,' says our author, 'was different too from the leprosy mentioned in Leviticus, and for which a temporary exclusion only was required, is evident, inasmuch as it was incurable. Am I a god, says the king of Israel, that this man expects me to heal a leper? and the cleansing of lepers was admitted among the most extraordinary of our Saviour's miracles. On the treatment of these diseases it will not be necessary to enlarge further here, than by saying, the various alteratives, mercurial, antimonial, and vegetable, have been employed, and with various reputed success. 'Although,' says Dr. Thomas, 'by paying a proper attention to regimen, and administering alteratives, we may be able somewhat to retard the progress of the disease, and thereby prolong the life of the patient; still, when the habit becomes generally tainted, all means will be likely to prove inefficacious.' In respect to the Greek elephantiasis, or Syrian leprosy, if we are to regard the affections as synonymous, it is agreed to be incurable. 'How

can we expect,' says Dr. Adams, 'to cure a disease which originates in the constitution, and which the constitution is unable to cure.' A generous diet, however, he adds, certainly protracts life, and renders it more tolerable. The treatment of the Barbadoes elephantiasis is directed principally in the first instance to the abatement of lymphatic irritation, and afterwards to support the tone of these vessels.

Of acne or spotted face there is an abundant variety. Eruptions on the face, especially on the forehead, chin, and temples, which do not extend to the body, are very common at all periods of life, but whether these distinct, hard, inflamed tubercles which are sometimes permanent for a considerable length of time, and sometimes suppurate very slowly and partially, are capable of being arranged accurately, as Dr. Willan proposes, under the varieties of acne simplex, punctata, indurata, and rosacea, admits of a doubt to say the least. The acne, or spotted face, is to be treated by internal remedies or by local astringents, according as the constitution appears to be affected, or the complaint is merely cutaneous, the symptoms characterising the one or the other state being for the most part rendered sufficiently obvious by the present state or previous history of the patient. Indeed the whole of cuticular medicine is resolvable into this principle. First ascertain how far the root of the evil exists in the interior of the frame, and how far the derangement is merely on the surface, and then proceed either to internal medicinals or to external applications.

Cutaneous absorption, or the promotion of this, is what we must always aim at in our endeavours to remedy chronic eruptions of the skin: and, when the disorders are attended with much local or systematic excitement, these absorbent powers must be such as act without much irritation, such as the mineral acids, either the sulphuric, the muriatic, or the nitric, which at the same time sufficiently stimulate the absorbent vessels of the surface, and serve to abate the prevailing irritation. Arsenic and mercurials appear to be more especially applicable to those states of the skin which are unconnected with much irritative disturbance, and in which more direct excitement is called for. We probably often increase and protract cutaneous complaints by the too indiscriminate and free use of these, especially of mercurials, from a vague notion of the alterative efficacy of these medicinals. In all affections of the surface cleanliness is one of the cardinal points upon which the treatment must turn, and we are disposed to think that independently of the one or two specific distempers and specific remedies, as mercury in syphilis, and sulphur in itch, we have not arrived hitherto at any satisfactory acquaintance with the principles of medicinal management, beyond that of exciting the excretory and absorbent power of the surface, abating local and constitutional irritation when they exist, preserving the bowels in a state of freedom or regularity, and correcting poverty of diet on one hand, and exciting, heating materials of food on the other.

It must be allowed, however, that several chronic affections of a cutaneous kind seem very much benefited by the decoction of the woods as it is called, decoct. sarsap. comp., which in connexion with Plummer's pill., the pil. hydrarg. submur., may be administered for some length of time when we find the cutaneous disorder of an obstinate nature, and when it assumes an anomalous character. Of the eruptions and derangements which are termed pseudo-syphilitic we shall have to treat in the article SURGERY.

In the course of the above remarks it will be seen that we doubt the correctness of those classifications which have been made by some modern authors, especially Willan and Bateman. It may be right, however, just to state the principles upon which these arrangements have been proposed and the classes into which the various affections of the skin are divided. The elementary terms then of Dr. Bateman, which he principally takes from Dr. Willan, are,

1. *Papula.* Pimple.—Little eminences on the skin not commonly containing a fluid, and in which he ranks strophulus or the eruptions which are common to very young children under the name of the red gum, or red gown, and tooth rash; these often appear in the healthiest children, and being attended by no constitutional derangement no medical treatment is demanded, unless indeed, under the feeling that it is right to attend to the stomach and first passages, we should be disposed to give the child a few grains of magnesia, or a few minims of sp. ammon. aromat.

2. *Squama.* A scale.—Disorders in which the cuticle comes off in the form of lamina. The lepra is one of the illustrations of a squamous as opposed to a porriginous disease.

3. *Exanthemata.* Rashes.—The febrile eruptions, such as measles and scarlatina, are exanthematous diseases.

4. *Bulla.* Bleb.—These are swellings containing a watery fluid. The nettle rash, and the vesicular disease called pemphigus, are included in this class. The nettle rash, when it is obviously caused by irritating matter taken into the stomach, requires emetics and purgatives. Beyond this, these vesicular affections are very little under the control of medicine.

5. *Pustula.* Pustule.—Common boils and distinct small pox are examples of pustular diseases. The porriginous affections are pustular as opposed to the leprous or scaly on one hand, and the herpetic or vesicular on the other.

6. *Vesicula.* Vesicle.—Some eruptions, instead of proceeding to pustular suppuration, continue vesicular; the vaccine disorder is more vesicular than pustular. Shingles are vesicular.

7. *Tuberculum.* Tubercle.—This, like the papula or pimple, is a flesh eruption as opposed to the pustular or vesicular, but the swelling is much larger. Acne, or spotted face, is an instance of a tubercular eruption.

8. *Macula.* Spot.—This designation merely points out discolored skin, as in the nœvi materni.

9. *Wheal.*—This has somewhat the character of the bulla or bleb, but it is not so permanent, nor does it contain a fluid.

10. *Furfur.* Scab.—Scurfy exfoliation, as in the disease called pityriasis, which consists of a yellowish color of skin extending over the prin-

cipal part of the body, the cuticle coming off in bran-like exfoliation. It lasts often for months or years, and does not seem to be much under the influence of medicine.

11. *Scab.*—Hard cuticle forming itself over superficial ulcerations.

12. *Stigma.* Specks.—Several together forming petechiæ.

435. *Tic Douleureux.*—Respecting the pathology and precise nature of nearulgia facialis or tic douleureux very little can be advanced that is satisfactory. Its seat is usually on the cheek bone, and it affects in a manner quite peculiar; for, beside that the pain is extreme and intolerant, it is accompanied by twitchings and convulsive darts, from which the name tic has been derived; and it is usually as protracted and obstinate as it is painful and peculiar.

Some have endeavoured to account for this affection by supposing it to be an inflammation of the neurilima, investing the particular nerve that is its seat; but its mode and manifestation seem inconsistent with the notion of inflammatory disorder even of the most chronic kind; and to attribute it to a particular condition of the brain is quite vague and nugatory, for it often lasts for years without the cerebral system seeming to be at all affected, and, even when comatose affection supervene upon it, one should rather incline to the inference that these last depended upon some altered condition of the nervous organisation and functions consequent upon the intensity and protraction of the disorder, than that the disorder resulted from the condition of the brain.

The remedies too seem inconsistent with the cerebral pathology of the malady; for nothing certainly has come so near to a specific operation in this complaint as very large quantities of those medicinals which go under the denomination of tonics; arsenic bark, and more especially carbonate of iron. We have seen cases, which, to say the least, came nearly up to the full malignancy of the disorder that have yielded to the carbonate of iron in drachm doses, repeated three times a day; and it would, we think, be right in all nascent affections menacing the actual establishment of neuralgia facialis to make trial of this last mentioned drug. All the narcotics, such as opium and henbane and hemlock have been tried without affording any thing beyond a temporary relief; even the division of the affected nerve has proved unavailing, and a most rigid attention to dietetic rules has been enjoined and practised under the notion of 'digestive organ' derangement, without at all fulfilling the expectation of prescriber or patient.

In concluding the present article it will scarcely be necessary to point out the books which the student of medicine will find his account in consulting. The use which we have made of most of the modern authors, who have written systems of medicine, is a proof of the value we set upon their labors. Indeed we have been fearful sometimes of transgressing even encyclopædian license by transferring sections of books into our pages. If, however, we have largely borrowed, it will be admitted that we have liberally acknowledged, and we should hope rather to have promoted the circulation, than interfered with the value, of the several works that have contributed towards the composition and compilation of the present article.

It will all along have been seen that we have been anxious to impress the peculiar nature of medical researches, and the different circumstances in which a student of medicine is placed from that of an enquirer into any other branch of science. It will have been perceived also, that, without regard to the restriction of uniformity, we have dwelt upon some parts of our subject more fully than others; thus on the head of nervous and mental ailments we may be considered as having entered into more detail than consisted with the limited and practical manner in which other affections had been discussed; to this we have perhaps been partly led by the feeling that our readers are not expected to be exclusively professional, and we have therefore been desirous of branching occasionally out from the dryness of mere detail, into something rather speculative, and of general interest.

But we will not conceal that our intention has further been to assist in freeing the science from the fetters of mere technicality, and to enforce the conviction that neither a combination of anatomical and physiological knowledge, nor a full acquaintance with disease and antidotes in a routine way, will suffice to form the philosophic and efficient practitioner of medicine.

We have already, in the introductory portion of the present treatise, introduced some few remarks from a sensible writer, Mr. Mansford, bearing upon this point, and we have the highest satisfaction in concluding the paper by presenting an extract from a little work which has been sent to us from our friend Dr. Stewart, the author, while these pages have been passing through the press. This little book, entitled On Tendency to Disease of Body and Mind, &c. strikes us as containing in a small compass much that is admirable in matter, joined with a singular felicity and impressiveness of manner; but the reader shall judge for himself.

'It must be always borne in mind, when we consider the different manifestations of mental or corporeal power, that it is not in the object or subject of any action, that the great virtue lies, but rather in the passion or function that grapples with it. Food and drugs have, in themselves alone, no more strength or operation, when applied to the lethargic or unwilling stomach, than a book or engraving has, when laid before the gaze of an untutored savage. Their admiration is merely the opportunity or occasion, upon which the vital energy is called into play; and it is the functional power, not the passive capacity, of any organ which is to be considered. Whether the application be made to the internal surface of the alimentary canal, or to an ulcerated extremity, it is still the living fibre which is excited and interested. For, though necessary to the transactions in which they bear a part, any articles of diet or medicine are subservient to various controlling powers, and can of themselves do nothing; neither are they in any sort of ac-

cordance with the phenomena to which they administer. Vitality bids defiance, to a certain extent, to chemical and mechanical laws, or at least regulates and overrules their sway; and its deficiency is always best estimated by the resistance which these last maintain, on some occasions, in opposition to it. This peculiar power is nevertheless bounded. Certain general laws hedge in the widest irregularities, and establish something like constancy in the occurrences belonging to natural functions. For instance, in digestion, the instrumentality of various organs is required, and these are more or less affected and disciplined by circumstance and habit; and then the subject matter must contain certain elements of nutrition, and be free from an excessive proportion of crude or poisonous alloy; but, after all, whatever be the diet, and whatever the precautions used as to time and preparation, it is still this unseen power of vital energy which acts and governs, and in fact, 'makes the food it feeds on.' If we look merely to secondary phenomena, without tracing them to their primary source, we shall not account for the condition of any one of the living functions. An explanation of the ultimate stages of digestion and assimilation will in vain be sought in the most scrupulous analysis of the quality, and in the most exact admeasurement of the quantity, of esculent substances, if at the same time the disorder or well-being of the complicated apparatus which is brought to bear upon them, be not estimated. How else shall we explain the impunity with which people in vigorous health feed upon the most indigestible fare, the dura ilia messorum, compared with the irritation which the simplest and properest food occasions, when the stomach is debilitated or diseased?

We draw from the foregoing considerations, that all the agents or circumstances which modify the living powers have not a direct or positive, but only an indirect or relative operation. It is their fitness and expediency, their practical effect, not their inherent virtue, and abstract definite qualities, which recommend them to our notice. For instance, when in the treatment of an injured joint, rest is enjoined at one period, on account of inflammation, and then motion is ordered, at another, to keep up the proper uses of the part, neither plan is of itself good or bad; but we have an example of the legitimate agency of the healing art, which alternately interferes or looks on, as it is judged proper to check the tendency of vital actions, or to trust entirely to them. In this way alone can we account for the remarkable similarity of effects brought about by causes very different in their nature and mode of operation. We know that, in the treatment of many diseases, it is now a minute dose of a poison, now a total change in the habit of life, which sets up a new action in the system. At one time the most active unremitting supply of corroborants is demanded, as in purulent discharges; at another, a total suspension of human agency, as in encouraging union by the first intention.

It is not possible to deny the truth of this statement without refusing credence to the majority of writers and speakers on all occasions of professional conference and consultation; and without taking a very partial and limited view of the laws of physiology, pathology, and therapeutics. But if we duly consider under what different circumstances the same series of external phenomena may exist, how different may be the conditions of the vital energy, and how various the aptitude of the inherent powers of the system, to profit by any opportunity of re-establishment; we shall be much less puzzled to explain these apparently discordant facts. By considerations such as these we can easily subdue all tendency to pyrrhonism, reconcile discrepences which would else appear startling, and account for various revolutions in theory and practice totally inexplicable in any other way. Hence, too, we learn to study, rather the varied applicability of remedial agents, than to confide in their specific power. We must, it is true, from our limited powers of penetration and comprehension, and from the influence of habit, look with more favorable eyes upon those instruments which we have proved, and be inclined to account for their efficacy upon principles which we have deduced from actual trial, or from the common fund of experience and observation. But, without denying the utility of a system of professional orthodoxy, we should be cautious of attaching ourselves with so much bigotry to any favorite class of remedies, as to exclude all others from their rank as auxiliaries. Our art should be, like the system which it aims to preserve, living and progressive; and we should learn not only what, but how to think.

We are then all prepared to admit that there must be causes operating which we cannot appreciate, and to acknowledge the assistance which we must always derive from the general laws which control life and health, and recovery from disease; but it is also certain that so long as we have the power of stepping in to alter the direction of the vital processes, and to originate new actions in the system, we are untouched by the suspicion of the vulgar, who, ignorant of these principles, frequently consider the medical practitioner inefficient when he is really exercising the greatest skill, and promoting the most beneficial results. In these matters, as in most others where we are vitally concerned, we can obtain only moral evidence, and must not expect demonstration. There is a balance of probabilities to be decided only by a majority of proof. In new and isolated cases, therefore, we have analogy only as our guide; and proceed with less satisfaction and confidence than in those which are more familiar. Where there is conflicting testimony, in favor of opposite methods, we must always suppose a variation in the circumstances of the disease and of the treatment. Where the most frequently repeated experiments establish the character of a remedy, we find still a call for attention to its application and management; as in the employment of mercury and venæsection. Even the inestimable value of the vaccine matter, as a preventive of small-pox, though established beyond doubt in a general view, is yet subject to fluctuation, from circumstances which modify its action and defeat its operation. and which prevent our regarding it as a sure specific. Our profession, in its practical capacity. being then not a science, but simply applying the me-

dical sciences (see the author's pamphlet on the Division of Labor in Medical Practice.—Hatchard and Son), we must go on reasoning and inferring, and nicely weighing contingencies, and acting upon general deductions from our multiplied observations, still prepared to find the fading system of to-day give place to the more enlarged and more refined theory of to-morrow; and we may leave to mathematicians the task of determining how far the power of human agency can be made to square exactly with the causes upon which depraved action depend, when diseases and their cures shall be reduced to definite proportions, medicine as an art abolished, and all such matters, not managed by physicians, surgeons, and accoucheurs, but settled by Cocker's Arithmetic!'

After some further reflections on the re-agency of moral causes, Dr. S. goes on to say—'The intellectual faculties and the affections are beings not to be talked of only, but re-agents, which may be made subservient to our purpose, and auxiliaries in our mode of cure. It is with a view to this important and practical end, that we enquire, whether it be ever allowed us to assemble these spirits of the deep, by throwing out the food upon which they feed, and to summon them by pronouncing the spell which they obey? In matters which we know to be under the control of habit, and so much modified by circumstance, shall we not endeavour to discipline and educate the unruly, and to elicit and develope those which are deficient? We cannot, it is true, create a passion; but we can perhaps lay a train for its appearance; we cannot either form a seed, or construct a plant; but we can cultivate the soil from which they spring, and provoke them by arrangements and contrivances of our own. Shall then the physician, who is, par excellence, the creature of real life, who is all things unto all men, the connecting link of all stages of society, the witness of every act, and the repository of every secret—shall he content himself with advising the frantic man to 'be calm,' and directing the hypochondriac to 'keep up his spirits?' Shall he not rather in critical circumstances exercise a temporary power of dictating, and provide 'ne quid damni capiat respublica?' 'De l'ascendant que les ames fortes ont sur les esprits foibles.''

To those who have engaged in the actual practice of the art, the above intimations respecting the peculiar nature of medical researches, and the necessity of something being appended to mere medical science, will be appreciated as indicative of a proper tone of thinking and feeling. With this extract we had intended to close the article; but, as we are called upon to fill up our page, we shall do it by transcribing the concluding sentences of an address, delivered some time since, preliminary to a course of chemical instruction.

'Let the student of medicine,' says the lecturer, 'be given to understand that science will prove nugatory, and learning a vain thing in the practice of physic, if they shall be calculated on as answerable to all the exigencies of morbid circumstance in the way that philosophy teaches planetary motions, or calculates upon phases in the celestial bodies.

'Good sense and independent judgment, and a ready discernment are, in medicine, what taste and correct feeling are to the fine arts—they are the links which bind the several parts of science into one comprehensive and consistent totality—they are that which may keep from the extravagance and mannerism, as artists would say, of a school—they infuse life, and soul, and order, into what, without them, would be a lifeless and confused mass of materials. Let then no opportunity be lost of getting knowledge, but with all your gettings get wisdom; or, in other words, cultivate that disposition of mind which shall at once enable you to learn from others, and judge for yourself, and which shall often direct you what to do, and what to leave undone, where testimony is unavailing and science impotent.

'With respect to your general conduct in society as members of a liberal calling, and as partaking in an especial manner of that responsibility which attaches to every individual in social life, I feel that it is not necessary for me to expatiate at large; but I shall just use the freedom of urging consistency of conduct amidst all the chances and changes of this precarious and oftentimes painful existence. Be on your constant guard against the usurping influence of those malignant passions which belong to our nature. Let the superior success of a rival practitioner, should such happen to be the case, in the district where you reside, be suffered to excite as little as may be the feelings or the manifestations of envy. Conscious of having done your best to deserve success, persevere, in spite of apparent or temporary obstacles, in the manly endeavour to gain success; and calmly leave the event to the disposal of a superior power.

'Let no temptation of temporary advantage impel you to the adoption of a measure, either of a public or private kind, of which, when you ask counsel of your conscience respecting its expediency, the reply of 'the man within the breast' is, Desist; for, when once you lose that self-respect which is only to be retained by a firm resistance to every thing of an equivocal nature, you not only lose with it peace of mind, but the very act of compliance unlocks the door to the more easy access of future errings.

'In the event of large success in your profession, and in the world, let your honors and emoluments be borne meekly. Recollect that your less fortunate rival has the same feelings, and perhaps equal merit with yourself; and that, seeing the most stable reputation in medicine may receive a shock as serious in its nature as it had been unlooked for and unmerited in its occurrence.

'You have much before you of endurance, of forbearance, of enjoyment. You have embraced a profession which is full of uncertainties and anxieties; but, at the same time, rich in high and important truths; pregnant with sources of satisfaction; and abounding with circumstances of delight. And I here reiterate the conviction which I have expressed on former occasions, that in spite of all the uncertainties of the art, and all the vexations its practice involves, it will be found that the qualified, and conscientious, and consistent, practitioners will meet with full cause of self-congratulation, on the score of conscious utility, and full reason for being contented and happy in his course and calling.'

INDEX.

As the numbers are not continued in the last parts of the article, except to mark the diseases, we have indicated some of the particulars pointed out in the following index by the page, and have then placed p. before the number.

MEDI'ETY *n. s.* } Fr. *mediété, mediocrité;*
MEDIOC'RITY, } Lat. *medietas, mediocritas.*
Middle state; between two extremes; moderate degree: moderation; temperance.

When they urge us to extreme opposition against the church of Rome, do they mean we should be drawn unto it only for a time, and afterwards return to a *mediocrity?* *Hooker.*

Men of age seldom drive business home to the full period, but content themselves with a *mediocrity* of success. *Bacon.*

There appeared a sudden and marvellous conversion in the duke's case, from the most exalted to the most depressed, as if his expedition had been capable of no *mediocrities.* *Wotton.*

Great wits have great errors, and great estates have great cares; whereas *mediocrity* of gifts or of estate hath usually but easy inconveniencies. *Bp. Hall.*

They contained no fishy composure, but were made up of man and bird; the human *mediety* variously placed not only above but below. *Browne's Vulgar Errours.*

He likens the *mediocrity* of wit to one of a mean fortune, who manages his store with great parsimony; but who, with fear of running into profuseness, never arrives to the magnificence of living. *Dryden's State of Innocence.*

Getting and improving our knowledge in substances only by experience and history, is all that the weakness of our faculties in this state of *mediocrity*, while we are in this world, can attain to. *Locke.*

MEDINA (Sir John Baptist), an eminent painter, was son of Medina de L'Asturias, a Spanish captain, who had settled at Brussels, where the son was born in 1660. He was instructed by Du Chatel; and afterwards made Rubens his principal model. He was both an historical and portrait painter; and was held in extraordinary esteem by most of the princes of Germany, who distinguished him by several marks of honor. He married young, and came into England in 1686, where he drew portraits for several years with great reputation, as he painted strong resemblances with remarkable freedom of touch, and a delicate management of tint. The earl of Leven encouraged him to go to Scotland, and procured him many engagements. He returned to England for a short time; but went back to Scotland, where he died, and was buried in the Greyfriars church-yard at Edinburgh in 1711, aged fifty-two. He painted most of the Scotch nobility, and the professors of Edinburgh; but was not rich, having twenty children. He was knighted by the duke of Queensberry, being the last knight made in Scotland before the Union.

MEDINA, the capital of Woolly, a kingdom of Western Africa, contains from 800 to 1000 houses, and is defended by a high wall, surrounded by a thick hedge. It stands in long. 12° 50′ W., and lat. 13° 38′ N.

MEDINA, a city of Arabia, next in honor to Mecca for its sacred connexion with the founder of the Mahometan faith. It contains the tomb of the prophet, though the orthodox do not believe the body to be enclosed in it, but to have been transported to heaven. Still this tomb is held in great veneration; but a visit to it is not considered in any very high degree meritorious, and is performed by few. Medina does not consist of more than 500 ill-built houses; and the sacred tomb itself is not superior to those which the founders of mosques usually erect. It is placed between those of the caliphs Abubeker and Omar: the building being hung with silk, which is renewed every seven years. The guard of forty eunuchs, according to Niebuhr, is chiefly designed to keep off the populace, who seek to carry off relics. Here is a very magnificent mosque, founded by the prophet, being supported by 400 columns, and containing 300 lamps, which are kept always burning. Jambo, on the Red Sea, is the port of Medina.

MEDINA DEL CAMPO, the ancient Methymna Campestris, an inland town of the province of Leon, Spain, has been the birth-place and residence of several of her kings. It is of good size, and has a neat square, with a noble fountain. The town is separated by the little river Zapardiel, into two parts. Here is a Jesuits' college, a respectable structure; and a well endowed hospital. This town has three annual fairs. Population between 5000 and 6000. The country around is rich in wine. Thirty-seven miles north-west of Segovia.

MEDINA DEL RIO SECO, an old town of Leon, is situated in a plain, watered by the Sequillo. It contains three parish churches, four convents, three hospitals, and about 8000 inhabitants. Noted in former times for its population, manufactures, and fairs, it received the name of India Chica, or the Little Indies. The castle is now entirely in ruins, and the whole place in a decayed state. Twenty-five miles north-west of Valladolid.

MEDINA SIDONIA is an ancient town of Spain, in Andalusia, having two churches, six monasteries, and about 5000 inhabitants. It has long given the title to a duchy; and the families of Medina Celi and Medina Sidonia are now united. Twenty-two miles south-east of Cadiz.

MEDIOLANUM, in ancient geography, a city of Italy, the capital of the Insubres, built by the Gauls, now called Milan. It was a municipium; a place of great strength; and the seat of the liberal arts; whence it had the name of Novæ Athenæ. See MILAN.

MEDIOLANUM AULERCORUM, an ancient town of Gallia Celtica, afterwards named Eburovicum Civitas (Antonine), corrupted to Civitas Ebroicorum, and this last to Ebroica; whence the modern name Evreux.

MED'ITATE, *v. a.* & *v. n.* } Fr. *mediter*
MEDITA'TION, *n. s.* } Italian *meditare;*
MED'ITATIVE, *adj.* } Span. *mediter;*
Lat. *meditor.* To plan or contrive; to think upon: as a neuter verb, to contemplate; muse; dwell upon with deep thought: the substantive and adjective correspond.

His delight is in the law of the Lord, and in his law doth he *meditate* day and night. *Psalm* i. 2.

Blessed is the man that doth *meditate* good things in wisdom, and that reasoneth of holy things. *Ecclus.* xiv. 20

Them among
Theer set a man of ripe and perfect age,
Who did them *meditate* all his life long.
Faerie Queene

Some affirmed that I *meditated* a war; God knows I did not then think of war. *King Charles.*

In *meditation*, those which begin heavenly thoughts, and prosecute them not, are like those which kindle a fire under green wood, and leave it so soon as it but begins to flame; losing the hope of a good beginning, for want of seconding it with a suitable proceeding. *Bp. Hall.*

Meditate till you make some act of piety upon the occasion of what you *meditate*; either get some new arguments against a sin, or some new encouragements to virtue. *Taylor.*

'Tis most true,
That musing *meditation* most affects
The pensive secresy of desert cell. *Milton.*

To worship God, to study his will, to *meditate* upon him, and to love him; all these bring pleasure and peace. *Tillotson.*

Like a lion that unheeded lay,
Dissembling sleep, and watchful to betray,
With inward rage he *meditates* his prey. *Dryden.*

Thy thoughts to nobler *meditations* give,
And study how to die, not how to live.
Granville.

Some thought and *meditation* are necessary; and a man may possibly be so stupid as not to have God in all his thoughts, or to say in his heart, there is none. *Bentley.*

Before the memory of the flood was lost, men *meditated* the setting up a false religion at Babel. *Forbes.*

MEDITERRANE', *adj.*, MEDITERRA'NEAN, or MEDITERRA'NEOUS. } Fr. *mediterranée*, of Lat. *medius* and *terra*. Encircled with land; inland; remote from the sea.

In all that part that lieth on the north side of the *mediterrane* sea, it is thought not to be the vulgar tongue. *Brerewood.*

It is found in mountains and *mediterraneous* parts; and so it is a fat and unctuous sublimation of the earth. *Browne.*

We have taken a less height of the mountains than is requisite, if we respect the *mediterraneous* mountains, or those that are at a great distance from the sea. *Burnet.*

The MEDITERRANEAN SEA, the Mare Internum of the ancients, extends in length from the strait of Gibraltar to the coast of Syria, nearly 2300 miles; but is of a breadth varying from 300 to 900 miles: the limits of its latitudes are 45° 54′ and 30° 5′. It is united to the Atlantic by the strait of Gibraltar, the Fretum Herculeum, Columnarium, and Gaditanum, of ancient geography, receiving the first two names from the promontories of Abyla and Calpe, the ancient pillars of Hercules; and the latter from Gades (Cadiz). The Arabs gave to the strait the name of Babuz Zukak, the gate of the way. Its length is fourteen leagues, and the breadth where narrowest six leagues.

The Mediterranean has been thought to have been originally a vast lake, the waters of which being suddenly increased by an irruption of the Black Sea, at the time of the formation of the latter, forced themselves a passage through the present strait of Gibraltar, and produced the inundation that submerged the great Atlantic island of Plato: Buffon, however, objects to this hypothesis on the ground that it is the ocean which runs into the Mediterranean, and not the latter into the ocean: he believes that the Mediterranean was in reality a lake, and that the strait was formed by a sudden convulsion produced by some earthquake, or violent effort of the ocean against this spot. This opinion, which was also that of several of the ancients, is supported by the similarity of the strata observed at equal elevations on the opposite sides of the strait.

The Mediterranean forms various *gulfs*, the three most considerable of which are the Gulf of Venice or Adriatic Sea (a name derived from the now small town of Adria, on the Tartara, nine leagues south of Venice, anciently washed by the sea); the Archipelago (Ægean Sea); and the Gulf of Tripoli on the coast of Africa.

Portions of this, the largest expanse of water in the world not denominated an ocean, have also other distinctive names. The space between the Balearic Islands and Spain is by the Spaniards called the Sea of Valencia (Mare Balearicum). That between Sardinia, Corsica, Italy, and Sicily, the ancient Tyrrhenian Sea, is named sometimes the Sea of Tuscany and of Sicily. The great gulf by which the Adriatic is entered is called the Ionian Sea, and the eastern extremity of the Mediterranean from the isle of Candia is denominated the Levant.

Gulfs of this sea, of a secondary description, are those of Lyon (Sinus Gallicus, Sinus Leonis), Genoa (Sinus Ligusticus), and Tarente (Tarentinus). The first extends from Cape St. Sebastian, in Catalonia, to the Isles of Hieres; the Gulf of Genoa, in its most extensive sense, from these islands to the promontory of Piombino; and the Gulf of Tarente is a branch of the Ionian Sea.

The *current* that flows into the Mediterranean from the ocean has been supposed to prove its level to be lower than that of the Atlantic, an effect which can only be produced by the loss of more of its water by evaporation than is restored to it by rivers, rains, &c.: its level is certainly also lower than that of the Red Sea. We are acquainted with but few authentic notices of the depth of the Mediterranean. In the channel between Sicily and Malta the greatest depth is 100 fathoms, while between Malta and Cape Bon there is not more than thirty fathoms water. The inward current is much stronger on the African shore of the strait of Gibraltar, and even at times an outward current is experienced on the opposite coast. From the strait the current sets strongly to the east along the coast of Africa, following its direction to the coast of Syria, where it sets to the north and to the west along the coast of Caramania, at the rate of one mile per hour. The current from the Black Sea passes to the south through all the channels of the Archipelago. A current sets into the Adriatic along the east coast quite to its head, and out on the opposite coast. The general current sets out along the coasts of France and Spain; but with the wind from north-west it is the reverse, the currents then setting in along the coasts of Spain and France; and indeed, throughout the sea, the currents are considerably affected by the winds.

The idea of a submarine current in the strait of Gibraltar rests on the following curious and almost decisive facts:—Dr. Hudson, in a paper communicated to the Philosophical Transactions, above a century ago, says, 'In 1712 M. de L'

Aigle of the Phœnix, off Marseilles, giving chace near Ceuta Point to a Dutch ship, came up with her in the middle of the gut between Tariffa and Tangier, and there gave her one broadside which sunk her. A few days after, the sunk ship, with her cargo of brandy and oil, arose on the shore near Tangier, at least four leagues to the west of the place where she sunk, and directly against the strength of the current; which has persuaded many men that there is a recurrency in the deep water in the middle of the gut that sets outward to the grand ocean, which this accident very much demonstrates.' Philosophical Transactions, vol. xxxiii. p. 192.

Lieutenant (afterwards admiral) Patton, when lieutenant of the Emerald, being overtaken with a very heavy gale of easterly wind, in approaching the rock of Gibraltar, when night came on it became necessary to lay the ship to, under a close-reefed main-topsail, to wait for day-light and better weather; and this was done as nearly as possible in the mid channel. About one o'clock in the morning lieutenant Patton observed an unusual darkness on the lee beam, and supposing it to be land, and the vessel to be in imminent danger, he instantly wore the ship, without waiting even to acquaint the captain. Finding it impossible to clear the land by setting sails, he saw that there was no chance of saving the ship but by trusting to the anchors. One of them was accordingly let go, but before it took effect the vessel struck the ground three times; but the ship, notwithstanding the very high swell, and the breakers within half a cable's length of the stern, rode fast till day-break, when the weather became more moderate, and the vessel was found to have drove in at the back of the rock of Gibraltar, by a counter current. In consequence of this narrow escape, lieutenant Patton was led to study the subject of the currents of the strait of Gibraltar.

'He had ascertained by experience,' says his brother, captain Patton, 'that when two fluids meet in a narrow channel, the one being lighter than the other, that which is heaviest will run out below, at the same rate exactly that the fluid which is lightest runs in above. Of the truth of this any person may satisfy himself by filling two long phials, one with salt water and the other with fresh; color one of them with ink, or any other substance to distinguish it, and place the mouths of the phials close together, holding them horizontally: the salt water, which is heaviest, will be seen to run out below, exactly at the same rate that the fresh water, which is lightest, runs in above. The same law of nature holds with respect to air, which is also a fluid; if, for example, the air in a room is more heated than the air in the outside, or next apartment, it will of consequence become rarified and lighter; if the doors be opened between them, and a lighted candle be placed on the floor of the passage of the door, the flame will blow inward with the cold air running in below; but if the candle is held up, near the upper part of the door, the flame will go outward with the warm and light air, blowing out as fast above as the heavy air comes in below.

'Lieutenant Patton, therefore, very naturally conceived that, if the water within the Mediterranean be heavier than the water in the Atlantic, the water of the latter, according to the laws of gravity and fluids, must of course run in above, and at the some rate the water of the Mediterranean, being heaviest, run out below; and in this particular case, as the cause must be perpetual, the effect must follow; and the upper or surface current never cease to run in from the Atlantic to the Mediterranean. In order to ascertain the fact, whether the water in the Mediterranean is actually heavier than the water in the Atlantic, Lieutenant Patton filled some bottles of sea-water, at a distance from all land, in the Atlantic, and also some bottles near the middle of the Mediterranean, which were afterwards carefully and accurately weighed; when a flask, containing one pound six ounces and five drachms of the Atlantic water, was found to be thirteen grains lighter than the same flask most exactly filled with an equal quantity of the Mediterranean water. The difference of weight seems small in the contents of a flask, but, on so large a body of water as the gut of Gibraltar must contain, is quite sufficient to account for the constant current which, from this cause, as lieutenant Patton has fully ascertained, runs from the Atlantic into the Mediterranean.'

To this testimony may be added the fact lately communicated to Dr. Marcet by Dr. Macmichael, on the authority of the British consul at Valencia, that some years ago a vessel was lost at Ceuta, on the African coast, and its wreck afterwards thrown up at Tariffa on the European shore, full two miles west of Ceuta.

The *tides* of the Mediterranean are all, on the whole, inconsiderable; but they have, in some places, a perceptible rise and fall. The greatest seems to be at Venice, where the extreme difference is three feet. At Marsala, in Sicily, the flood comes from the north-east, and the rise is two and a half to three feet; at Naples one foot, at Toulon one to two feet, on the coast of Syria only six inches. The winds also produce partial and irregular elevations of water, which in many instances have probably been mistaken for tides: when strong westerly winds blow, for any continuance, they force an accumulated body of waters through the strait, which raises the general level of the sea, while strong Levant winds have a contrary effect; nevertheless it is observed that, in the sea of Tuscany, south-east winds cause a greater elevation of the tide; on the north coast of Sicily, particularly at Marsala, where, as we have observed, the common rise is but three feet, with a strong south-east wind it is as much as ten or eleven. In the strait of Euripus, which separates Negropont from the continent, a singular phenomenon occurs: during the first eight days of the moon, as well as from the fourteenth to the twentieth day, and for the last three days, the tide ebbs and flows regularly four times in the twenty-four hours; while, during each of the other days it ebbs and flows with great force from eleven to fourteen times, though the difference of elevation never exceeds two feet. Aristotle is said to have drowned himself here from a feeling of humiliation at being unable to account for this.

In the strait of Messina is found the celebrated Charybdis, which at present is not considered a very dangerous agitation of the waters. It occupies a space of about 100 feet in circumference opposite a little cove east of Faro light-house called Calo Faro, and about 250 yards from the shore. The agitation only takes place when the current is ebbing, or setting through the strait from the north, when its stream makes with the shore a number of angles of incidence which retard its progress, so that it takes two hours to reach Charybdis from the entrance of the strait. Here it produces a considerable rippling, but no vortex; for the light substances thrown into it, instead of being carried down, are tossed about on the surface. The depth of water here is about eighty fathoms. Between the tides there is a period of repose, of never more than an hour nor less than a quarter of an hour. When the wind blows strongly from the south against the current, the waves rise to a dangerous height for open boats; but the only danger to a large vessel is of being driven on shore by the stream, her sails and rudder being in this spot useless. In order to prevent such accidents, expert seamen, with proper boats, are kept constantly ready on the beach, at Messina, to put off to the assistance of any vessel. On the Calabrian shore, opposite Charybdis, is the equally celebrated rock of Scylla, a little promontory the extremity of which is 200 feet in perpendicular height. At low water many rocks show themselves at its base; and these, with the currents and waves rushing with great fury and noise into the neighbouring caverns, doubtless gave rise to the poetical fiction of 'the dogs howling round the monster Scylla.' However this rock is not without a certain degree of danger, which in some measure authorises the proverb of 'falling upon Scylla in trying to avoid Charybdis;' for the tide setting directly on it, and the depth being too great for anchorage, a ship is liable to be driven on it in either a calm or a contrary wind. On the summit of the promontory is a castle, and on the south side a little village.

The *Fata Morgana* of the strait of Messina is to the ignorant as wonderful a phenomenon as was Scylla or Charybdis to the ancients. 'In fine summer days,' says a late French traveller, 'when the weather is calm, there rises a vapor from the sea which, when it has acquired a certain density, forms, in the atmosphere horizontal prisms, whose sides are so disposed that they reflect for some time like mirrors the objects on the coast, exhibiting by turns the city of Messina, trees, animals, men, mountains, &c. This representation continues for eight or ten minutes, when shining irregularities are observed on the surface of the prisms, that first render confused the objects they reflect and the picture dies away gradually.'

The Mediterranean being the receptacle of but four rivers of magnitude, while a stream from the Atlantic continually runs into it, its waters are as saline as those of the latter. According, indeed, to the late experiments of Dr. Manet they are even more so. The singularity of this has been explained upon the supposition that the Mediterranean is not supplied, by the rivers which flow into it, with a quantity of fresh water sufficient to replace what it loses by evaporation under a burning sun, aided by a powerful radiation from the African shores and the parching winds blowing from the adjacent deserts: and philosophers suppose that the only reason why this sea does not gradually increase in saltness, and become converted into saturated brine, is the under current of water already mentioned, salter than the ocean, which runs out at the strait of Gibraltar, and unloads its waters of their excess of salt.

This sea has several springs of fresh water rushing up from amidst the salt, the most celebrated of which is in the grand port of Tarento, called the Little Sea, and at some distance from the mouth of the Galesus: it is in such force and abundance that it may be taken up without the least mixture of salt water.

The *winds* most prevalent in the Mediterranean blow between north-west and north-east, with few intermissions, for nine months of the year, and almost constantly during summer. In the other three months (February, March, and April) south-east and south-west winds prevail. The nature and effects of the winds in the Mediterranean, however, differ greatly according to locality. On the south of Spain the Solano wind (called in Italy the Sirocco) is from the south-east. These, blowing from the sandy deserts of Africa, bring with them, particularly to Sicily and Naples, a degree of insupportable heat. During their continuance the elasticity of the air seems to be lost, and both the body and mind are reduced to debility. At Palermo, where the intensity of the Sirocco is greatest, it never lasts more than forty-eight hours, but at Naples it sometimes continues for weeks. The Mistral is a north-west wind which blows with great violence down the Gulf of Lyon. The Kamsin a S. S. W. wind, which blows in Egypt in March and April, generally not more than three successive days at a time. While it continues, the atmosphere seems to be on fire, and acquires a purple tinge; and the transient blasts which succeed from time to time, resemble the breath from a furnace. This is the period in Egypt when the plague, which seems to be indigenous in this country, bursts forth in all its violence. The Kamsin signifies the wind of fifty days, thus named because it only happens, it is said, during fifty days of March and April. The Samiel, or poisonous wind of the Arabs, which at Bassora blows from north-west, at Bagdad from west, at Mecca from the east, and in Syria from the south-east, and which is also the Simoom of the desert, is similar in its nature and effects. It contains a great portion of azote.

Towards the east of the Mediterranean the temperature of the atmosphere varies more with the wind than in any other part of the world. In the Archipelago the northern winds, Tramontana, the Etesian winds of the ancients (though this denomination was also extended to all periodical winds), which blow at times with great violence during summer, bring a considerable degree of cold, and obscure the horizon in a remarkable manner. They are very injurious to vegetation, and cause violent head-aches. A few

hours of these winds cover the mountains of Epirus with snow, which as speedily disappears with a few hours of the Sirocco. On the coasts of the Levant there are land and sea breezes; the latter, on the coasts of Turkey, is called the Imbat. In some places the former are exceedingly baneful, particularly in the island of Candia, where they are said frequently to suffocate those exposed to them.

The Marobia is a northern phenomenon of this sort, most probably deriving its name from Mare Ubbriaco, or drunken sea, as its movement is apparently very inconsistent. It occurs principally on the southern coast of Sicily, and is generally found to happen in calm weather, but is considered as the certain precursor of a gale. The Marobia is felt with the greatest violence at Mazzara, perhaps from the contour of the coast. Its approach is announced by a stillness in the atmosphere and a lurid sky; when suddenly the water rises nearly two feet above its usual level, and rushes into the creeks with amazing rapidity; but in a few minutes recedes again with equal velocity, disturbing the mud, tearing up the sea-weed, and occasioning noisome effluvia: during its continuance the fish float quite helpless on the turbid surface, and are easily taken. These rapid changes (as capricious in their nature as those of the Euripus) generally continue from thirty minutes to upwards of two hours; and are succeeded by a breeze from the southward, which quickly increases to heavy gusts.—*Smyth's Memoir of Sicily*.

The *temperature* of the Mediterranean varies greatly, according to peculiar circumstances. Towards the south the climate approaches to that of the tropics, while on the north the variations of the seasons are more considerable. The greatest severity of winter, however, does not exceed some days of light frost, and the snow never lies more than a few hours in the valleys of the coasts. The Adriatic being frozen, in the years 860 and 1234, is recorded as a singular phenomenon. In the eastern part of the sea, and particularly amongst the islands of the Archipelago, the winters are disagreeable, from the prevalence of the Sirocco, accompanied by heavy storms of rain, thunder, and lightning. The climate of Attica, on the contrary, is constantly dry and serene. The medium heat of the sea around Sicily, at a depth of from ten to twenty fathoms, by Six's thermometers, is from 73° to 76°, which, being 10° or 12° warmer than the water outside Gibraltar, accounts for the greater evaporation and consequent currents.—*Smyth's Memoir*, p. 184.

Coral is the most important af the *marine productions* of the Mediterranean. It is found in great abundance round the Lipari Islands, in the strait of Messina, and on the coast of Barbary; but the French and Sicilians are the only nations who make its fishery an object of industry. The former, on the coast of Barbary, is said to produce a profit of 360,000 francs per annum. That of the Sicilians, round Lipari and Volcano, employs about sixteen boats; and that in the strait of Messina eighteen to twenty, with eight men in each. The produce is about 3000 lbs. weight per annum. The spots on which this substance is found, in the strait, are nearly in the middle, from the Faro to opposite the church of the Grotto, on the Sicilian shore, an extent of six miles; and on two small rocky spots opposite the canal of St. Stephen, eight miles south of Messina. The depth here is from sixty to ninety fathoms. This space is divided into ten portions, one of which only is fished every year, so that each has ten years rest, the time found necessary to allow the coral to grow. To the extremities of a wooden cross pieces of net are fastened; the machine is sunk by heavy weights, and dragged over the bottom, breaking off the branches of coral which thus get entangled. A trifling quantity of this substance is also fished in the gulf of Ajaccio (Corsica), and in some spots near Sardinia and Minorca. Eleven other species of the gorgona, or sea fan, are found in this sea.

It also possesses a great variety of naked mollusca, amongst which the medusa pulmo is the most common in the seas of Italy. The holuthuria phasalis (Portuguese man of war of our seamen) is also common in this sea, and is named by the French la vellette and la galere, the sail and the galley. The species of testaceous mollusca are also very numerous: the murex afforded the celebrated purple dye of the ancients. Oysters, limpits, scollops, and muscles, are abundant; and of the latter is a singular species, found in the gulf of Nice and the Adriatic, enclosed in masses of limestone at the bottom of the sea. It is called, from its resemblance to that fruit, the sea date (pholas dactylus) and much esteemed by the epicures of Rome and Naples. The lanna pinna, or sea pine, is a bivalve, which affords a kind of tow, or silk, that is manufactured into gloves, stockings, &c. These fish are taken principally round Cape St. Vito, the south point of the Gulf of Taranto. The paper nautilus is also met with, but rarely.

The common lobster and crab abound on the coast of Tuscany; and the squilla arenaria is a very delicate prawn, of the Adriatic. Ichthyologists reckon thirty-eight genera of fish, divided into upwards of 100 species, in the Mediterranean and its tributary rivers.

But the indolence of most of the modern races who inhabit its coasts prevents the fisheries of this sea from being carried to any extent as an object of commerce; and with the exception of the tunny fish, anchovies, and sprats, the whole produce is consumed. The tunny enters the Mediterranean in shoals from the ocean in spring, and passes through into the Black Sea and Sea of Azoph, in whose shoal waters it is supposed to spawn: they return to the ocean in autumn. 'It is said,' observes Mr. Tuckey, 'that these fish enter the Black Sea along the coast of Asia and return along that of Europe; Aristotle and Pliny, who noticed this fact, account for it by supposing the fish to see better with the right eye than with the left. It is however more natural to suppose that the prevailing winds are the cause; for when the fish enter the channel they are chiefly from the south, and, when they return, from the north; the fish therefore prefer the smooth water under the weather shore. These fish are also said to spawn in the Italian seas.

The French carry the tunny fishery to the greatest extent. These fish arrive on the coast of Provence from June to September inclusive, and are taken both with hook and line and with nets.'

'The thonaire, used here, is a number of nets joined together and hauled on shore like the seine, when the shoals of fish appear, for whose arrival a strict watch is kept by persons placed on the hills. The madrague is an enclosure of nets, consisting of several apartments, like a succession of rooms opening one into the other, the nets which compose them being kept in a perpendicular position by floats and weights. The outer apartment, called the hall, has an opening through which the fish enter, and when it is full the opening is closed by another piece of net, let down by the fishermen who attend in the boat. The fish are then frightened by the noise of the men into the second apartment, and so on to the others, there being from four to eight, until they get into the last, which is called the chamber of death, and when this is full the nets that form it are raised to bring the fish to the surface, when they are killed with spears and harpoons.'

This fishery is also carried on on the coast of Valencia, from April to September, with nets in the same manner, called almadrabas, and on the coast of Sardinia, the fisheries of which produce upwards of £70,000 a year. The Sicilians carry on this fishery near the isles of Maretimo, &c.; and the Neapolitans in the gulf of Taranto. The female fish are much the largest, weighing from 800 lb. to 1200 lb. The method of curing is by cutting off the head and dividing the fish into six or eight pieces: it is then either simply salted, or is boiled and preserved in oil. The belly pieces are preferred for this last purpose, and the fish thus prepared is called by the French thon marine, and by the Italians tarantilla, from its being prepared chiefly at Taranto: the livers and roes are also salted.

The anchovy enters this sea in shoals in May, June, and July, and is an important object of the French fishery. The preparation consists in cutting off the head, which is said to be bitter, emptying the inside, and salting and packing in little barrels. The most esteemed are those taken near Gorgona; but the people of Frejus are considered the most expert in curing them. The French, Valencians, and Italians, also take great quantities of sprats on their coasts, which they both smoke and salt. The season of this last fishery is from December to March.

The sword-fish is taken in the gulfs of Genoa and Messina. The fishery commences on the Calabrian shore in April, and lasts till July, when it begins on the opposite coast of Sicily and lasts till August. The fish enter the gulf from the north close along the Calabrian shore, and in their return from the south keep close to the Sicilian shore. Twenty to thirty feluccas, and a number of smaller boats are employed in this fishery with harpoons, or it is carried on with nets called palmidores.

The fish chiefly taken in the gulf of Lepanto are mullet, which are dried in the sun for the consumption of the Greeks during their fasts, and the roes made into boutaraga, a kind of inferior caviar, which is exported to France and Italy. The preparation of this object consists in highly salting the roes, pressing them between boards, and then washing and drying them in the sun, or smoking. The mackarel is a visitor of the Mediterranean; and some writers have given the herring to this sea, but the fish called harengade and celerin, on the coast of France, is now ascertained to be only a large sprat. The red turmulet abounds on the coast of Egypt, particularly in winter; the raia aquila is also chiefly met on this coast: the barbel is likewise to be found on the lakes of Naples.

The hippocampus, or cavallo marino of the Italians, abounds in the gulf of Naples and the Adriatic, where it is washed up dead on the shores, and when dried is preserved as a curiosity, the head having a resemblance to that of the horse, and the tail to that of the shrimp. The Italian women take it to increase their milk, and use it externally as an anodyne to the breast: it has also been used with honey and vinegar in hydrophobia. The gadus minutus arrives periodically, and is followed by numbers of large fish, to the great joy of the fishermen, who make them their food.

Instances have occurred of great cetaceous animals being taken in the Mediterranean, but they are considered only as individuals which have strayed thither. A pike-headed whale, 100 feet long, was taken in 1620 near the island of Corsica; and in 1790 a round-nosed whale was killed on the coast of Provence. The whale which Pliny mentions as having entered the port of Ostia, in Claudius's reign, clearly excited the attention of the Roman populace by its being considered a wonder. But this sea habitually yields the grampus (delphinus orca), the delphinus feres, the common porpoise (delphinus phocæna), and the bottle-nosed porpoise (delphinus delphis) the dolphin of naturalists. The modern Greeks are said to have a great veneration for this latter.

Here are of amphibious animals, of the genus phoca, three species—the common seal (phoca vitulina), the hooded seal (phoca monachus), and the little seal (phoca pusilla). They frequent the desert isles, particularly of the Ionian Sea and the Archipelago: the Zantiots are the only people that take them for their skins and fat. Two species of sea turtle are also met with in the Mediterranean—the loggerhead and hawksbill: the sea birds are, various species of the gull and diver, the storm-petrel, tern, sea swallow, and wild duck.

We have room but to add an extract from an ingenious paper of Dr. Robertson's adddressed to Dr. Brewster, in the Edinburgh Philosophical Journal, 1819, on the luminous appearance of the waters of this sea: a specimen of which is seen in the Fata Morgana, already alluded to.

'In addition to these observations,' says this writer, 'I beg leave to offer what I have remarked respecting the very luminous appearance of its waters on the slightest agitation, so frequently perceived after sunset, especially during the warm season. By many people this has been supposed to be caused by certain minute luminous insects existing in the water, to the disengagement of phosphorus from the excrements, or

remains of fishes that have died, and other putrid matters. By seamen this luminous appearance, from the slightest agitation, has been considered as generally the precursor of blowing weather, and I am persuaded, from repeated observation, that the remark is as correct as it is general.

'This luminous appearance is but rarely met with during the winter season, compared to the frequency with which it occurs in the summer and autumn. I have never seen it when the wind blows fresh from a northerly point, or when the temperature of the air is low; nor have I remarked it in any great degree but in calm weather, when the temperature of the air was high, and especially as the wind was changing towards a southerly point, and I have always observed that this luminous matter was emitted most strongly immediately preceding the fall of rain or an overcasting of the sky, showing a disposition to the formation of that meteor. Upon the whole I am of opinion that this appearance of light, on the agitation of the waters of the Mediterranean, is somehow or other connected with evaporation, and that it is occasioned by the rapid evolution of the electric fluid in that process; that probably it rarely depends on phosphoric matters existing in the waters; and, after repeated and careful observations by myself and others, I have never been able to trace its appearance as depending on the existence of insects, nor could I ever perceive any thing peculiar in the sensible qualities of water taken up in such circumstances, or that was different from the water of the sea when it did not give out this luminous appearance.'

ME'DIUM, *n. s.* Lat. *medium.* A mean; any thing interposing or intervening; hence the middle term, or step, of an argument; middle place or degree.

Whether any other liquors, being made *mediums*, cause a diversity of sound from water, it may be tried. *Bacon.*

All the old philosophy consented that virtue and vice had no *medium* between them, but whatsoever was not evil was good. *Bp. Taylor.*

He who looks upon the soul through its outward actions often sees it through a deceitful *medium*, which is apt to discolour the object. *Addison.*

The parts of bodies on which their colours depend are denser than the *medium* which pervades their interstices. *Newton.*

To find the *medium* asks some share of wit,
And therefore 'tis a mark fools never hit.
Cowper.

Medium, in philosophy, that space or region through which a body in motion passess to any point: thus ether is supposed to be the medium through which the heavenly bodies move (see Ether); air the medium wherein bodies move near our earth; water the medium wherein fishes live and move; and glass is also a medium of light, as it affords it a free passage.

Medium, Arithmetical, or arithmetical mean, or medium rei; that which is equally distant from each extreme, or which exceeds the less extreme as much as it is exceeded by the greater, in respect of quantity, not of proportion; thus nine is a medium betwixt six and twelve.

Medium, Circulating. Upon this prolific topic we expected (see our article Bank) to see the public mind and the procedures of the monied interest in a far different state to that in which we find them, at the date of drawing up this article. While of the issues of the Bank of England an account is periodically afforded, of the banking system (if such there be), in this the highest and most influential quarter, no intelligible account is allowed to circulate beyond the court of directors; and even to the proprietors no statement of profits is afforded. We have only therefore to add to that article that the bank of England has returned to cash payments, and, having been allowed to plant branch banks at the distance of not less than sixty miles from London, has made the experiment with considerable success in several large towns; that this year (1829) the country banks have withdrawn all their small notes from circulation, with little or no apparent difficulty to themselves; but that the result on the manufactures and mercantile interests is far from being fully ascertained. For the manner in which the various mercantile towns abroad conduct their banking measures we must refer to what we have been able to collect respecting them in the several separate articles. Some hints on the connexion of the doctrine of Currency with that of our Corn Laws may be found in the article Corn Laws. From a writer there quoted we may add the following extract as worthy the consideration of all classes:—

'Equity demands, in favor of the landed proprietor, an equivalent for the exclusive charges fixed by law on his estate: that equivalent must be a protecting duty on foreign corn imported; the amount of the duty is a fit subject for discussion: but here we are arrested by the past variations in the value of our currency, and the price which we have first to settle is the price of money; for it is impossible to establish a fixed protecting duty with fairness, when the standard of value is itself unfair. This appears to me the very core of the whole subject, the point on which you have committed the most fatal errors. You have fought for high prices, and concurred in measures which render them impossible. You have retained your monopoly, but consented to a change in the value of money which must destroy its efficacy. The ground which you still endeavour to defend is no longer tenable; and the points which you have surrendered ensure your defeat. If I might venture to allude to the conduct of the landed interest in the last session of parliament (1825–1826), I should say, that it affords conclusive evidence of the blindest adherence to the single object of high prices, coupled with an entire misapprehension of the means by which this object might be attained, and of the general principles on which the prices must depend; the price of commodities, and of corn among the rest, is compounded of two ingredients—of the supply in the market compared with the demand, and also of the value of money; itself the measure of value, liable, however, to great variation, in proportion to its quantity.

'The value of money is the inverse ratio of

its quantity; the supply of commodities remaining the same. Increase the quantity of money, prices rise: decrease the quantity of money, prices fall. On the other hand, the quantity of money remaining the same, increase the quantity of commodities, prices fall: decrease the quantity of commodities, prices rise. Thus a decrease of the quantity of money produces the same effect on the price of a commodity as an increase of the quantity of the commodity itself; if corn be that commodity, an addition to the value of money, such as the diminution of its quantity occasions, ensures as effectually a fall in the price of corn as the opening of the ports and free importation: in which of the two cases prices would fall lowest is a simple question of proportion between the increased supply of corn and the decreased quantity of money. These truths are elementary, and admitted as axioms; yet the conduct of the landed interest proceeds on a virtual denial of their validity. The high price of corn being their declared object, they direct their whole strength to the preservation of their monopoly of the supply, and at the same time contribute their support to measures designed to diminish the quantity of money and to increase its value. Their whole attention is absorbed by one half of the object of price—they look only to the supply, they disregard the measure of value.'

Medium, Geometrical, or medium personæ, is that where the same ratio is preserved between the first and second as between the second and third terms; or that which exceeds in the same ratio or quota of itself, as it is exceeded: thus six is a geometrical medium between four and nine.

MED'LAR, *n. s.* Sax. mæꝺ, from its being used in mead. The Mespilus of Linné, which see.

You'll be rotten ere you be half ripe
And that's the right virtue of the *medlar*.
Shakspeare.

October is drawn in a garment of yellow and carnation; with a basket of services, *medlars*, and chesnuts. *Peacham.*

Men have gathered from the hawthorn's branch
Large *medlars*, imitating regal crowns. *Philips.*

The leaves of the *medlar* are either whole, and shaped like those of the laurel, as in the manured sorts; or laciniated as in the wild sorts. *Miller.*

MED'LE, Med'ly, *v. a.* & *n. s.* Med'ley, *n. s.* & *adj.* } Goth. *medal*; Swed. *medel*, mingled. To mingle or mix (obsolete as a verb): a mixture; miscellany; confused mass or congeries: medley is used by Dryden for mingled; confused.

Ther is nothing that savoureth so sote to a child as the milke of his norice, ne nothing is to him more abominable than that milke whan it is *medled* with other mete. *Chaucer. Personnes Tale.*

Some imagined that the powder in the armory had taken fire; others, that troops of horsemen approached: in which *medly* of conceits they bare down one upon another, and jostled many into the tower ditch. *Hayward.*

I'm strangely discomposed;
Qualms at my heart, convulsions in my nerves,
Within my little world make *medley* war.
Dryden.

Mahomet began to knock down his fellow-citizens, and to fill all Arabia with an unnatural *medley* of religion and bloodshed. *Addison.*

They count their toilsome marches, long fatigues,
Unusual fastings, and will bear no more
This *medley* of philosophy and war. *Id. Cato.*

MEDMANN, or Mettmann, a town in the Prussian states of the Rhine, in the duchy of Berg, having manufactures of cotton, woollen, and hardware. Population 4000. Six miles E. N. E. of Dusseldorf.

MEDUL'LAR, *adj.* Medul'lary. } Fr. *medullaire*; from Lat. *medulla*, pith. Pertaining to the marrow.

The back, for the security of that *medullary* substance that runs down its cavity, is bent after the manner of the catenarian curve. *Cheyne.*

These little emissaries, united together at the cortical part of the brain, make the *medullar* part, being a bundle of very small, thread-like channels or fibres. *Id.*

MEDUSA, in mythology, one of the three Gorgons, and the only one subject to mortality. She was celebrated for her personal charms, and the beauty of her locks. Neptune became enamoured of her, and obtained her favors in the temple of Minerva. This profanation provoked Minerva, who changed the beautiful locks of Medusa into serpents, the sight of which turned the beholders into stones: but Perseus, armed with Mercury's axe, cut off Medusa's head, from whose blood sprang Pegasus and Chrysaor, together with the innumerable serpents that infest Africa. He placed Medusa's head on the ægis of Minerva, which he had used in his expedition; and the head still retained its petrifying powers.

Medusa, in zoology, a genus of vermes, belonging to the order of mollusca. The body is gelatinous, roundish, and depressed; and the mouth is in the centre of the under part of the body. Many species, on being handled, affect with a nettle-like burning, and excite a redness. They were named by the Greeks πνευμα θαλασσιος, and by the Romans pulmo marinus, or sea lungs. They attributed medicinal virtues to them. Dioscorides says that, if rubbed fresh on the diseased part, they cured the gout in the feet, and kibed heels. Ælian adds that they were depilatory; and, if macerated in vinegar, would take away the beard. Their phosphoric quality is well known; nor was it overlooked by the ancients. Pliny observes that if rubbed with a stick it will appear to burn, and the wood to shine all over.

Medusa Capillata, the capillated medusa, is a very singular animal; it is easily broken and destroyed by a touch; its shape is rounded, rising into a convexity in the middle, where it is therefore thickest; on the under side it is plain, and on this there is visible a rough, or, as it were, an echinated circle, within which there run eight pairs of rays from the centre toward the circumference; from the centre there arise also a number of curled appendages. This species is met with in vast abundance, floating on the surface of the water about Sheppey Island in Kent and elsewhere on that coast. This species is called by many authors pulmo marinus, or the sea lungs

MEDUSA LUMINOSA, a species discovered by Sir Joseph Banks, to which he has given the name of luminosa, as, when brought aboard by the casting net, it had the appearance of metal violently heated, and emitted a white light. These luminous animals are one of the causes of that appearance of the sea which has been mentioned by many navigators, and for which various reasons have been assigned. They seemed to emit flashes of light exactly resembling those of lightning, only not so considerable; but so frequent, that sometimes eight or ten were visible at the same moment.

MEDUSA UNDULATA, the waved medusa, has the edges waved, with fangs on the projecting parts; four orifices beneath, between which rises a stem divided into eight large ragged tentacula. These animals swim in large companies in search of food, with their tentacula in continual motion, with which they seize their prey, and convey it to their mouths; they vary in size, the largest being generally about eight inches in diameter. They vary likewise in the number of their tentacula; some have only two; others four, six, and some eight, but they rarely exceed that number. So powerful is their embrace, that whatever prey comes within their reach never escapes. They subsist on insects, small fish, &c.

MEDWAY, a river of England, which rises in the Weald of Sussex, and, entering Kent near Ashurst, runs by Tunbridge, and thence continues its course towards Maidstone. It is navigable for large ships to Rochester Bridge, and thence for vessels and barges to Maidstone, the tide flowing up to that town. The distance between its mouth, where the fort at Sheerness is erected, and Rochester Bridge, is between sixteen and eighteen miles. In this part of the river, the channel is so deep, the banks so soft, and the reaches so short, that it is one of the best and safest harbours in the world; and ships of eighty guns ride a-float at low water, within musket-shot of Rochester Bridge. Nor is there an instance upon record, that any of the royal navy ever suffered here by storms, except in the dreadful tempest in November 1703, when the Royal Catharine was driven on shore, sunk, and lost. On the banks are two castles, one at Upnor, to defend the ships between that and the bridge; the other is Gillingham Castle, well furnished with cannon, which commands the river. There is also a platform of guns at a place called the Swam, and another at Cockham Wood. But the principal fort is at Sheerness.

MEED, *n. s.* Sax. meꝺ; Teut. *meeten, myde*; Goth. *met*. Reward; hence present; gift; recompense, good or evil.

But if I do this thing wilfulli I haue *meide*? but if aghens my wille dispendyng is bitaken to me.
Wiclif. 1 *Cor*. ix.

Ne for prayer, ne for *mede* he wil not be corrupt.
Chaucer. Personnes Tale.

He knows his *meed*, if he be spide,
To be a thousand deaths, and shame beside.
Spenser.

Whether in beauties glory did exceed,
A rosy garland was the victor's *meede*.
Faerie Queene.

Thanks to men
Of noble minds is honourable *meed*. *Shakspeare.*

Plutus, the god of gold,
Is but his steward; no *meed* but he repays
Seven-fold above itself. *Id. Timon of Athens*

He must not float upon his watery bier
Unwept, and welter to the parching wind,
Without the *meed* of some melodious tear.
Milton.

A long and prosperous enjoyment in the land of Canaan was the *meed* set before them, if they should obey and make good their part of the covenant.
Barrow.

If so, a cloak and vesture be my *meed*,
Till his return no title shall I plead.
Pope's Odyssey.

MEEK, *adj.*
MEEK'EN, *v. a.*
MEEK'LY, *adv.*
MEEK'NESS, *n. s.*
Goth. and Swed. *mink*; Danish, *mygr*; Hebrew, מך. Mild or pliable of temper; 'not easily provoked:' to meeken is to soften: meekness, gentleness; mildness; suavity.

Moses was very *meek* above all men.
Numb. xii. 3.

Hir *meke* praiere and hir pitous chere
Made the markis for to han pitee.
Chaucer. Cant. Tales.

Be therefore, O my dear lords, pacifyed,
And this mis-seeming discord *meekly* lay aside.
Faerie Queene.

That pride and *meekness* mixt by equal part,
Do both appear to adorn her beauty's grace.
Spenser.

You sign your place and calling, in full seeming,
With *meekness* and humility; but your heart
Is crammed with arrogancy, spleen, and pride.
Shakspeare.

Both confessed
Humbly their faults, and pardon begged, with tears
Watering the ground, and with their sighs the air
Frequenting, sent from hearts contrite, in sign
Of sorrow unfeigned, and humiliation *meek*.
Milton.

No pride does with your rising honours grow
You *meekly* look on suppliant crowds below.
Stepney.

We ought to be very cautious and *meek*-spirited, till we are assured of the honesty of our ancestors.
Collier.

When his distemper attacked him, he submitted to it with great *meekness* and resignation, as became a Christian. *Atterbury.*

The glaring lion saw, his horrid heart
Was *meekened*, and he joined his sullen joy.
Thomson.

If thou art rich, then shew the greatness of thy fortune, or, what is better, the greatness of thy soul, in the *meekness* of thy conversation; condescend to men of low estate, support the distressed, and patronize the neglected. *Sterne.*

MEER, or
MERE, *n. s.*
MEERED, *adj.*
Sax. mepe; Belg. *meer*. A lake or river: hence a boundary: meered is bounded, or relating to a boundary.

What, although you fled! why should he follow you?
The itch of his affection should not then
Have nickt his captainship; at such a point,
When half to half the world opposed, he being
The *meered* question.
Shakspeare. Antony and Cleopatra.

MEEREN, or MEER (John Vander), an esteemed painter, born in 1627. He chose for his subjects sea-pieces, landscapes, and views of the

sea and its shores; which he painted with great truth, as he had accustomed himself to sketch every scene after nature. He also painted battles with approbation. He died in 1690.

MEEREN, or MEER (John Vander) the Young, an eminent landscape-painter, supposed to have been the son of the preceding, of whom he learned the rudiments of the art; but, being deprived of his instructor before he had made great progress, he became a disciple of Nicholas Bergham, and was accounted the best of those who were educated by that admired master. In the style of his master he painted landscapes and cottages, with peasants at their rural occupations and diversions; but he very rarely introduced cows, horses, or any other animals, except goats and sheep, which last are highly finished. His touch is scarcely perceptible, and yet the colors are admirably united. He died in 1688. His genuine works bear a very high price, and are esteemed even in Italy.

MEERJAOW, a town of the province of Canara, Hindostan, on an inlet of the sea. It is supposed to have been the Musiris of the ancients; and was nearly destroyed by Hyder Aly when he invaded the province in 1773. The neighbouring forests abound with teak and black pepper. Long. 74° 36′ E., lat. 14° 27′ N.

MEERMAN (Gerard), a Belgic writer on jurisprudence, was born at Leyden in 1722; and was an author at the age of seventeen. Between 1744 and 1748 he was abroad in several voyages; and, on his return, was appointed pensionary counsellor of Rotterdam. In 1766 he was made counsellor of the high tribunal of the chace of Holland and West Friseland; and died at Aix-la-Chapelle, December 15th, 1771. The emperor created him a baron of the German empire; and Louis XV. invested him with the order of St. Michael. He possessed an immense collection of books and MSS.; and presented several of the latter to the French king's library. Among his works may be specified Novus Thesaurus Juris civilis et canonici, 1751—54, 7 vols. folio; and Origines Typographicæ, 1765, 4to.

MEERMAN (John), son of the preceding, was born in 1753, and early distinguished for learning. He studied at Leipsic under Ernesti; and completed his education at Leyden, where, in 1774, he took the degree of LL.D. He now visited France, Italy, Germany, Great Britain, and Ireland; and, on his return home, he was elected burgomaster of Leyden, a situation which he soon resigned. Under Louis Buonaparte he was director of the fine arts and of public instruction in Holland; and, on the union of that country to France, he was made a count of the empire. He died August 19th, 1815, leaving to the city of the Hague the rich library of his father, which he had largely increased. His best known published works, including a supplementary volume to his father's Thesaurus, are the History of William, earl of Holland, and king of the Romans, 5 vols. 8vo.; The Relations of Great Britain and Ireland, of Austria, of Prussia, and of Sicily, 1787—94, 5 vols. 8vo.; The Relations of the North and North-West of Europe, 1905-6, 6 vols. 8vo.; containing observations made by the author in his travels.

MEERSCHAUM, in mineralogy, a kind of clayey earth, the keffekil of Kirwan. Color yellowish and grayish-white. Massive. Dull. Fracture fine earthy. Fragments angular. Opaque. Streak slightly shining. Very soft, sectile, but rather difficultly frangible. Adheres strongly to the tongue. Feels rather greasy. Specific gravity 1·2 to 1·6. Before the blowpipe it melts on the edges into a white enamel. Its constituents are, according to the analysis of Klaproth, silica 41·5, magnesia 18·25, lime 0·50, water and carbonic acid 39. It occurs in the veins in the serpentine of Cornwall. When first dug, it is soft, greasy, and lathers like soap. Hence the Tartars use it for washing clothes. In Turkey it is made into tobacco-pipes, from meerschaum dug in Natolia, and near Thebes. See *Jameson's Mineralogy* for an entertaining account of the manufacture.

MEET, *adj.* } Sax. mæte; Goth. *mæti*, in
MEET'LY, *adv.* } measure. See METE. Fit; proper; adapted; suitable. 'Meet with' is a low phrase for 'even with' you.

> Arcite is ridden anon unto the toun,
> And on the morwe, or it were day light,
> Ful prively two harneis hath he dight,
> Both suffisant and *mete* to darreine
> The battaille. *Chaucer. Cant. Tales.*

Ah! my dear love, why do you sleep thus long, When *meeter* were that you should now awake? *Spenser.*

If the election of the minister should be committed to every parish, would they choose the *meetest*? *Whitgift.*

> I am a tainted wether of the flock,
> *Meetest* for death.
> *Shakspeare. Merchant of Venice.*

> To be known shortens my laid intent,
> My boon I make it, that you know me not,
> Till time and I think *meet*. *Id. King Lear.*

Niece, you tax Signior Benedick too much; but he'll be *meet with* you. *Shakspeare.*

As for the comfort of conjugal society, what other did our good God intend in the making of that *meet* helper? *Bp. Hall.*

The eye is very proper and *meet* for seeing. *Bentley.*

MEET, *v. a.* & *n. s.* } Sax. metan; Belg.
MEET'ER, *n. s.* } *moetan*; Teut. *moten*;
MEET'ING, } Goth. & Swed. *mota.*
MEETING-HOUSE, *n. s.* } To encounter; come face to face: hence to oppose in conflict or hostility; close with; join; to find; light upon; accost: as a neuter verb, to assemble; congregate: it frequently takes the preposition *with* after it. A meeting is an encounter; assembly interview, or place of assembly or meeting Meeting-house, an old but well-fashioned word signifying a dissenting place of worship.

His daughter came out to *meet* him with timbrels and dances. *Judges* xi. 34.

They appointed a day to *meet* in together. 2 *Maccabees.*

When he cometh to experience of service abroad, he maketh as worthy a soldier as any nation he *meeteth with.* *Spenser.*

> When shall we three *meet* again,
> In thunder, lightning, or in rain?
> *Shakspeare. Macbeth.*

Falstaff at that oak shall *meet with* us. *Shakspeare.*

There are beside
Lascivious *meeters*, to whose venomed sound
The open ear of youth doth always listen. *Id.*

Let's be revenged on him; let's appoint him a *meeting*, and lead him on with a fine baited delay. *Id.*

Met'st thou my posts? *Id.*

We *meet with* many things worthy of observation. *Bacon.*

Before I proceed farther, it is good to *meet with* an objection, which if not removed, the conclusion of experience from the time past to the present will not be found. *Id.*

A little sum you mourn, while most have *met*
With twice the loss, and by as vile a cheat. *Creech.*

Mean while our primitive great sire, to *meet*
His godlike guest, walks forth. *Milton.*

To *meet* the noise
Of his almighty engine, he shall hear
Infernal thunder. *Id.*

Their choice nobility and flower
Met from all parts to solemnize this feast. *Id.*

The materials of that building happily *met* together, and very fortunately ranged themselves into that delicate order, that it must be a very great chance that parts them. *Tillotson.*

I knew not till I *met*
My friends, at Ceres' now deserted seat. *Dryden.*

Not look back to see,
When what we love we ne'er must *meet* again. *Id.*

Had I a hundred mouths, a hundred tongues,
I could not half those horrid crimes repeat,
Nor half the punishments those crimes have *met.* *Id.*

If the fathers and husbands of those, whose relief this your *meeting* intends, were of the household of faith, then their relicks and children ought not to be strangers to the good that is done in it, if they want it. *Sprat's Sermons.*

He yields himself to the man of business with reluctancy, but offers himself to the visits of a friend with facility, and all the *meeting* readiness of desire. *South.*

Royal mistress,
Prepare to *meet with* more than brutal fury
From the fierce prince. *Rowe's Ambitious Stepmother.*

Our *meeting* hearts
Consented soon, and marriage made us one. *Rowe.*

The nearer you come to the end of the lake, the mountains on each side grow higher, till at last they *meet.* *Addison.*

What a majesty and force does one *meet with* in these short inscriptions: are not you amazed to see so much history gathered into so small a compass? *Id. on ancient Medals.*

Hercules' *meeting with* pleasure and virtue, was invented by Prodicus, who lived before Socrates. *Addison.*

His heart misgave him that the churches were so many *meetinghouses;* but I soon made him easy. *Id.*

To me no greater joy,
Than that your labours *meet* a prosperous end. *Granville.*

Of vice or virtue whether blest or curst,
Which *meets* contempt, or which compassion first. *Pope.*

Since the ladies have been left out of all *meetings*, except parties at play, our conversation hath degenerated. *Swift.*

Meg fain wad to the barn gane
To win three wechts o' naething;
But for to *meet* the deil her lane,
She pat but little faith in. *Burns.*

MEGALE POLIS, written dividedly by Ptolemy and Pausanias; or conjunctly Megalopolis, according to Strabo; an ancient town of Arcadia, built under the auspices of Epaminondas, after the battle of Leuctra; many inconsiderable towns being joined together in one great city (whence the name), the better to withstand the Spartans. Strabo says it was the greatest city of Arcadia. It was destroyed by Cleomenes III., king of Sparta.

MEGALESIA, AND MEGALENSES LUDI, feasts and games in honor of Cybele or Rhea, the mother of the gods, held on the 12th of April by the Romans, and famous for great rejoicings and diversions of various sorts. The Galli carried the image of the goddess along the city, with drums and other music, in imitation of the noise made to prevent Saturn from hearing the cries of his infant son Jupiter, when he was disposed to devour him.

MEGANTICK, a lake of Lower Canada, on the borders of New England, from which the river Chaudiere in part arises. It is nine miles in length, and two in average breadth, running deeply into the land. It is surrounded by some excellent meadows, and altogether the scenery is beautifully picturesque here: large groups of stately trees ranging above each other until they crest the summit of the rising lands. The waters abound with fish; and the country is the resort of almost every species of game.

MEGARA, in ancient geography, a noble city, capital of Megaris, which for many years carried on war with the Corinthians and Athenians. It had for some time a school of philosophers, called the Megarici, successors of Euclid the Socratic, a native of Megara. Their dialect was the Doric; changed from the Attic, which it formerly had been, because of the Peleponnesian colonists who settled there. Megara was situated at a distance from the sea. Its port was called Nisæa, from Nisus, son of Pandion II., who obtained Megaris for his portion, when the kingdom of Athens was divided into four lots by his father. He founded the town, which was eighteen stadia, or two miles and a quarter from the city, but united with it, as the Piræus with Athens, by long walls. It had a temple of Ceres. The site is now covered with rubbish, among which are standing some ruinous churches. The place has been named from them Dode Ecclesiais, the Twelve Churches; but the number is reduced to seven. The acropolis or citadel, called also Nisæa, was on a rock by the seaside. Some pieces of the wall remain, and a modern fortress has been erected on it, and on a less rock near it. Megara consists now only of a few cottages on the slope of an eminence, divided in the middle.

A few inscriptions are found, with pedestals fixed in the walls and inverted; and also some mutilated statues. One of the former relates to Atticus Herodes, and is on a pedestal which supported a statue erected to him when consul, A. D. 143, by the council and people of Me-

gara, in return for his benefactions to the city. In the plain behind the summits is a large basin of water, with scattered fragments of marble, the remains of a bath or fountain, which is recorded as in the city, and remarkable for its size and ornaments, and for the number of its columns. The spring was named from the local nymphs called Sithnides. The stone of Megara was of a kind not found any where else in Hellas; very white, uncommonly soft, and consisting of cockle shells. This was chiefly used, and, not being durable, may be reckoned among the causes of the desolation at Megara, which is so complete that one searches in vain for vestiges of the many public edifices, temples, and sepulchres, which once adorned the city. Megara was engaged in various wars with Athens and Corinth, and experienced many vicissitudes of fortune. It was the only one of the Greek cities which did not flourish under their common benefactor Adrian. Another benefactor was Diogenes, son of Archelaus, who bestowed on the Megarensians 100 pieces of gold towards building their towers, and also 150 more, with 2200 feet of marble, towards re-edifying the bath. This Diogenes was one of the generals employed by the emperor Anastasius on a rebellion in Isauria, and took the capital Claudiopolis, A. D. 494.

MEGARIS, in ancient geography, the country of the Megareans, is described as a rough region, like Attica; the mountain called Oneian, or the Asinine, now Macriplayi, or the Long Mountain, extending through it towards Bœotia and Mount Cithæron. It belonged to Ionica or Attica, until it was taken by the Peloponnesians in the reign of Codrus, when a colony of Dorians settled in it. This territory had Attica on the east, Bœotia on the north and west, and the Isthmus of Corinth on the south.

MEGASTHENES, a Greek historian in the age of Seleucus Nicator, about A. A. C. 300. He wrote concerning the oriental nations, and particularly the Indians. His history is often quoted by the ancients. What now passes as his composition is spurious.

MEGIDDO, in ancient geography, a town of Galilee, mentioned (Josh. xvii. 11) among the cities of Manasseh, in the tribe of Issachar or Asser, on the west side of the Jordan, near an open plain, fit for drawing up an army in battle array. It was situated on the north, contrary to its position in the common maps. The Canaanites, being tributary to the Israelites, dwelt in it, Josh. xvii. It was rebuilt by Solomon, 1 Kings ix; and is remarkable for the deaths of Ahaziah king of Israel, and Josiah king of Judah, 2 Kings ix. 27; xxiii. 29.

MEGNA, THE, a river of Hindostan, formed by the junction of numerous streams, which issue from the mountains on the northern boundary of Bengal. The principal of these is the Brahmapootra. Below Dacca it is joined by the Issamutty, Dullasary, Luckia, and Ganges, after which it pours its immense waters into the bay of Bengal, forming several large islands at its mouth. Between these the tide enters with great rapidity, forming in the spring tides what is called the Bore, and which in a few minutes rises twelve feet high. The sand-banks run nearly thirty miles into the sea. This appears to be the proper entrance of the Ganges.

ME'GRIM, *n. s.* Fr. *migraine*; Gr. ημικρανια. Disorder of the head.

In every *megrim* or vertigo there is an obtenebration joined with a semblance of turning round.
Bacon's Natural History.

There, screened in shades from day's detested glare,
Spleen sighs for ever on her pensive bed,
Pain at her side, and *Megrim* at her head. *Pope.*

MEHALLET KEBEER, a city of Lower Egypt, the capital of the district of El Garbie, in the Delta, and standing on a canal between the eastern and western branches of the Nile. It is of considerable magnitude and commercial importance, so as to be called Kebeer 'the great,' and possesses manufactures of cloth and sal ammoniac. Long. 31° 24′ E., lat. 30° 50′ N.

MEHKOOR, a populous district of Hindostan, in the province of Berar; situated between two ranges of mountains, and subject to the Nagpore rajah.

MEHWAS, a district of the province of Gujerat, Hindostan, situated on the south-east bank of the Puddar. The inhabitants, formerly Hindoos, have been converted in considerable numbers to the Mahometan religion, and are marauders, who live by plunder. Any one who can head twenty horsemen considers himself an independent chief. They breed horses and cattle, but cultivate little of the soil.

MEIBOMIUS (John Henry), a learned German, who was professor of physic at Helmstadt, where he was born, and at Lubec. He wrote the Life of Mæcenas, published at Leyden, in 4to. 1653, with several other learned works.

MEIBOMIUS (Henry), son of the preceding, was born at Lubec in 1638; he became professor of physic at Helmstadt; and, besides medical works, published Scriptores rerum Germanicorum, 3 vols. folio, 1688; a very useful collection, first begun by his father.

MEIBOMIUS (Marcus), another writer of the same family, who published a collection of seven Greek authors, who had written upon ancient music, with a Latin version by himself, dedicated to queen Christina of Sweden, who invited him to her court. But his enthusiasm in favor of ancient music subjected him to a degree of raillery, that made him leave the court of Sweden. His edition of the Greek mythologists, and notes upon Diogenes Laertius in Menage's edition, show him to have been a man of learning.

MEJERDAH, a river of Tunis, the Bagrada of the ancients, in the western part of that territory, and running along the borders of Algiers, till it falls into the Mediterranean at Porto Farina. The country beside its banks is level, and very rich, in consequence of which it is deeply impregnated with soil, and often presents the same discolored aspect as the Nile. It is one of the most considerable streams in Barbary.

MEINUNGEN, a principality of Saxony forming part of the duchy of Saxe-Meinungen, and divided into the Oberland and the Unterland, two districts situated at some distance from each other. The extent of the whole is

about 448 square miles. The Unterland is the larger of the two, containing nearly 350 square miles, and a population of 40,000. It is traversed by the Werra, and has extensive forests, several iron mines, and mines of coal and cobalt. The manufactures, which are not considerable, are of woollen, linen, and hardware. The chief export is salt from the mines of Salzungen. The Oberland has 16,000 inhabitants, and is a hilly district of the great forest of Thuringia.

Meinungen, a town of the above principality, situated amongst mountains, on the Werra. Since 1681 it has been the residence of the dukes of Saxe-Meinungen, who have an elegant palace here, with a library and a depôt of archives. Here is also a lyceum, council-house, and state-house. The chief manufacture is black crape. Population 4200. Twenty-one miles north of Schweinfurt.

MEINY, n. s. Sax. menigu; old Fr. *mesnie, mesne; Lat. mansio*. A house or family; a retinue or train.

They summoned up their *meiny*; strait took horse;
Commanding me to follow, and attend. *Shakspeare.*

MEISSEN, or Misnia, a circle of Saxony, on both sides of the Elbe, and extending from Bohemia on the south, to Prussian Saxony on the north. Part of it was ceded to Prussia at the congress of Vienna in 1815, but it has still an area of 1600 square miles. It is one of the best cultivated parts of Saxony, and yields corn, fruit, flax, hops, and pasturage, in abundance, and, in a few districts, wine. It contains also the principal manufactures of the kingdom in woollen, linen, and cotton. Dresden itself lies within its limits. Inhabitants 298,000.

Meissen, a town of Saxony, the capital of the former margraviate and circle of this name, is situated on the left bank of the Elbe, at its junction with the Meissa, in one of the most beautiful valleys of Saxony. It is divided into three parts: the upper and middle towns, and the suburbs. On a rock, eighty feet in height, stand the remains of an ancient castle, built by the emperor Henry I.; and on a neighbouring eminence the rock of Afra, the ancient monastery of that name. The objects worth notice in this town are the fine Gothic cathedral, the chapter-house, and a covered bridge over the Elbe. This place is also distinguished for its porcelain manufacture, the clay of which is yielded in the neighbourhood. Population 4000. Fifteen miles W. N. W. of Dresden.

MEISSNER (Augustus Theophilus), an author of German romances, was the son of a Saxon quarter-master, and born in 1753 at Bautzen in Lusatia. He studied law and the belles lettres at Leipsic and Wittemberg, and became keeper of the archives at Dresden. His literary career commenced in his translating comic operas from the French. In 1785 he obtained at Prague the chair of belles lettres, and twenty years after was invited to Fulda, to direct the superior schools. He died in 1807. Meissner translated Hume's England into German, 1777-1780, and wrote a number of historical romances and other works. His Sketches have been translated into French, Danish, and Dutch.

MEKRAN, a large maritime province of Persia, extending along the shore of the Indian Ocean to Scinde, and on the west and north to Kerman and Seistan. It has been little traversed by travellers. Alexander the Great, in returning from his Indian expedition, passed through this province, and the sufferings and hardships endured by his army gave the most unfavorable impression of the nature of the country. The northern and inland part is the Baloochistan of modern geography, and separated from the maritime part by a range of mountains. See Baloochistan. The entire province is occupied by a great number of independent chiefs, whose power and territory is always fluctuating. The whole military force of the country may amount to about 25,000 men. Around Bunpore the people are migratory, and live in tents of black hair. The women of Mekran are not confined as in other Mussulman countries. The chief place at present is Kei.

MEL, honey. See Honey.

MELA (Pomponius), an ancient Latin writer, who was born in Hispania Bætica, and flourished under Claudius. His three books of Cosmography, or De Situ Orbis, are written in a concise, perspicuous, and elegant manner. Isaac Vossius gave an edition of them in 1658, 4to., with copious notes.

MELADA, Meleda, or Melit, an island of the Austrian empire, on the coast of Dalmatia. It formerly belonged to the republic of Ragusa, and has a town of the same name; a good harbour, and a large monastery. Population 2000. Long. of the eastern point 17° 58' E., lat. 43° 5' N.

Melada, a small barren island of Dalmatia, at the entrance of the canal of Zara, to the north of Isola Grossa. It is inhabited chiefly by fishermen.

MELALEUCA, in botany, the cayputi, or cajeput-tree, a genus of the polyandria order, and polydelphia class of plants: cal. quinquepartite, superior: cor. pentapetalous; the filaments are very numerous, and collected in such a manner as to form five pencils; there is one style: caps. half-covered with the calyx, formed like a berry, trivalved and trilocular. The species are all natives of India and the South Sea Islands. The most remarkable is,

M. leucodendron, from a variety of which (the latifolia, or broad-leaved leucodendron) the cajeput oil is obtained: a medicine in very high esteem among the eastern nations, particularly in India. It is said to be obtained by distillation from the fruit. When brought into this country it is a liquid of a greenish color, of a fragrant but very peculiar odor, and of a warm pungent taste. Hitherto the oleum cajeput has been little employed either in Britain or on the continent but in India it is used both internally and externally, and is highly extolled for its medical properties. It is applied externally where a warm and peculiar stimulus is requisite; it is employed for restoring vigor after luxations and sprains.

MELAMPODIUM, in botany, a genus of the polygamia necessaria order, and syngenesia class of plants; natural order forty-ninth, com-

positæ; receptacle palæaceous and conical; pappus monophyllous and valve-like; CAL. pentaphyllous.

MELAMPUS, in fabulous history, a celebrated soothsayer and physician of Argos, son of Amythaon and Idomenea or Dorippe. He lived at Pylos in Peloponnesus. His servants once killed two large serpents who had made their nests at the bottom of a large oak; and Melampus paid so much regard to their remains, that he raised a funeral pile and burned them upon it. He also took their young ones, and fed them with milk. Some time after this, the young serpents crept to Melampus, as he slept on the grass near the oak; and, as if sensible of the favors of their benefactor, they wantonly played around him, and softly licked his ears. This awoke Melampus, who was astonished at the sudden change which his senses had undergone. He found himself acquainted with the chirping of the birds, and all their rude notes, as they flew around him. He took advantage of this supernatural gift; made himself perfect in the knowledge of futurity, and Apollo instructed him in the art of medicine. He soon after cured the daughters of Prœtus, by giving them hellebore, which from that circumstance has been called melampodium; and, as a reward, he received the eldest princess in marriage. The tyranny of his uncle Neleus, king of Pylos, obliged him to leave his native country; and Prœtus gave him part of his kingdom. About this time the personal charms of Pero, the daughter of Neleus, had gained many admirers; but the father promised his daughter to him only who should bring him the oxen of Iphiclus. Bias, who was one of her admirers, engaged his brother Melampus to steal the oxen. Melampus was caught in the attempt and imprisoned; and nothing but his services as a soothsayer and physician could have saved him from death. But when he had taught the childless Iphiclus how to become a father, he not only obtained his liberty, but also the oxen; and with them he compelled Neleus to give Pero in marriage to Bias. A severe distemper, which had rendered the women of Argos insane, was totally removed by Melampus; and Anaxagoras, the king, rewarded his merit by giving him part of his kingdom, where he established himself, and where his posterity reigned during six generations. He received divine honors after death.

MELAMPYRUM, cow-wheat, a genus of the angiospermia order, and didynamia class of plants; natural order fortieth, personatæ: CAL. quadrifid: COR. upper lip compressed, with the edges folded back: CAPS. bilocular and oblique, opening at one side; there are two gibbous seeds. There are four species, all natives of Britain, and growing spontaneously in corn fields. They are excellent food for cattle; and Linnæus tells us that, where they abound, the yellowest and best butter is made. Their seeds, when mixed with bread, give it a dusky color, and produce vertigo.

MELANCHOL'Y, *n. s.* & *adj.* } Fr. *melan-*
MELANCHOL'IC. } *colič*; Latin *melancholia*, of Gr. μελαν black, and χολη bile. A disease formerly supposed to proceed from an abundance of black bile, a species of madness; gloomy; pensive; hypochondriac temper.

He protested that he had only been to seek solitary places by an extreme *melancholy* that had possessed him. *Sidney.*

I have neither the scholar's *melancholy*, which is emulation; nor the musician's, which is fantastical; nor the courtier's, which is proud; nor the soldier's, which is ambitious; nor the lawyer's, which is politick; nor the lady's which is nice; nor the lover's, which is all these; but it is a *melancholy* of mine own, compounded of many simples, extracted from many objects, and indeed the sundry contemplation of my travels, in which my often rumination wraps me in a most humorous sadness. *Shakspeare.*

How now, sweet Frank; art thou *melancholy*? *Id.*

It is a false slander raised on Christianity, that it maketh men dumpish and *melancholic*. *Bp. Hall.*

All these gifts come from him; and, if we murmur here, we may at the next *melancholy* be troubled that God did not make us angels. *Taylor's Holy Living.*

Think of all our miseries
But as some *melancholy* dream which has awaked us
To the renewing of our joys. *Denham.*

The king found himself at the head of his army, after so many accidents and *melancholick* perplexities. *Clarendon.*

Moonstruck madness, moping *melancholy*. *Milton.*

This *melancholy* flatters, but unmans you;
What is it else but penury of soul,
A lazy frost, a numbness of the mind? *Dryden.*

If he be mad, or angry, or *melancholick*, or sprightly, he will paint whatsoever is proportionable to any one. *Id.*

He observes Lamech more *melancholy* than usual, and imagines it to be from a suspicion he has of his wife Adah, whom he loved. *Locke.*

The commentators on old Ari-
Stotle, 'tis urged, in judgment vary:
They to their own conceits have brought
The image of his general thought:
Just as the *melancholick* eye
Sees fleets and armies in the sky. *Prior.*

In those deep solitudes and awful cells,
Where heavenly pensive contemplation dwells,
And ever musing *melancholy* reigns. *Pope.*

This sudden view of my danger strikes me with *melancholy*; and, as 'tis usual for that passion above all others to indulge itself, I cannot forbear feeding my despair with all those desponding reflections which the present subject furnishes me with in such abundance. *Hume on the Human Understanding.*

MELANCTHON (Philip), the celebrated contemporary and fellow-laborer of Martin Luther, was born at Bretten, in the Lower Palatinate of the Rhine, in Saxony, on the 16th of February, 1497. His mother was the daughter of John Reuter, for many years mayor of that town, and his father, George Schwartzerd, a native of Heidelburg, who had settled at Bretten in consequence of his marriage, and filled the office of engineer, or commissary of artillery under the palatinate princes Philip and Rupert. In compliance with a custom very prevalent at that time among the learned, our reformer's name was afterwards changed, by his friend Reuchlin or Capnio, from Schwartzerd, signifying black earth, to Melancthon, a Greek appellation of similar import. The conduct of his early studies devolved chiefly on his maternal grandfather

Reuter, who was well qualified for the task, and affectionately solicitous for his improvement. He was first placed at a public school in his native town; but, a contagious disorder having found its way into this seminary, he was withdrawn, and pursued his studies under private tuition. In the Latin language he had for his preceptor John Hungarus of Pforzheim, a scholar of considerable merit, who was delighted with the proficiency of his pupil. At Pforzheim he likewise entered on the study of Greek, which he diligently and successfully cultivated. Happening to lodge at the house of a relation who was sister to John Reuchlin, that elegant scholar was struck with the early proofs of his genius, and presented him with a Greek grammar and a Greek and Latin lexicon. At the age of thirteen he had made so great a proficiency as to write several poetical pieces, and, among others, a comedy, which he dedicated to his friend Capnio, who, on that occasion, gave him the name that he ever afterwards bore.

From Pforzheim, where he resided nearly two years, Melancthon proceeded to the university of Heidelburg, then celebrated for its eminent professors in the different branches of learning; and here he soon so much distinguished himself as to be selected to write many of the public discourses of the professors and others: his credit for learning indeed was so great, that count Leonstein committed to his care the education of his two sons. At this early age he composed his Rudiments of the Greek Language. At Heidelburg he formed an acquaintance with various learned men, particularly the celebrated Pallas, who was for many years the brightest ornament of the academy: but he continued here not more than three years; the place not being thought favorable to his constitution, which was naturally feeble. This circumstance, together with the mortification of being refused a higher degree in the university merely on account of his youth, induced him to remove to Tubingen, a town in the duchy of Wurtemberg. He now attended particularly to the mathematics, jurisprudence, logic, medicine, and theology.

Melancthon was not yet seventeen when, in the year 1513, he took his degree of M. A., and commenced a course of private teaching. Not long after he became a public lecturer in the university on the learned languages, logic, ethics, mathematics, and divinity. His elegant classical taste was the theme of universal admiration, and it was at this period he commenced the restoration of Terence, whose works he arranged in their present poetical form out of the confused prose into which they had been reduced through the ignorance of transcribers. The attention of the learned was now universally attracted to him; and Erasmus declared that he was destined to eclipse himself. The venerable Latimer, too, we find speaking of him in the highest terms, and recommending him strongly to the patronage of king Edward VI.

After residing six years at Tubingen our young reformer removed (25th August 1518), on the invitation of the elector of Saxony, to the university of Wittemberg. So great was the esteem in which he was held at Tubingen, that Simler says, 'The whole city lamented his departure. No one can conceive or estimate how much the academy lost of distinction and emolument when he left.' At Wittemberg his station as Greek professor first brought him into contact with Luther, whom he had the honor of instructing in that language, and who ever readily acknowledged his literary superiority. His public lectures are said sometimes to have been attended by 1500 persons. On his first arrival he found the university in a wretched condition, both as to literature and philosophy; a single copy of the most celebrated Greek classics could not be found in print; and the students were obliged to write out passages as they were explained to them. Melancthon set himself diligently to diffuse the knowledge of this important language. In his first year he delivered lectures on Homer, and on the Greek of the epistle to Titus; all the principal theologians attended him, and all classes were inspired with the love of Greek. His ardor and diligence were indeed too great for his health, and we find the elector Frederick urging him to take wine for the support of his weak frame, and offering him the best in his own cellars. He announced, in an oration delivered in the month of October, a plan for reforming the studies of youth. In this address he particularly urges the study of the Greek philosophy, and the sacred scriptures, promising his pupils every aid that his own industry or erudition could afford. Melancthon was fully aware of the erroneous subtleties of the Aristotelian philosophy, and of the mischievous support which it had so long afforded to false and unscriptural tenets, by involving every subject in metaphysical obscurity; but he possessed a mind which could discriminate accurately, and he therefore carefully availed himself of the general prejudice in its favor, for the illustration and support of real philosophy and religion. With this view he composed a number of elementary treatises, which were, for a long time, in general use in the Lutheran schools, among which may be particularly noticed his Logic; Physics; Ethics; and a Treatise on the Soul: which were applauded by the most competent judges of the age as much calculated to aid the labors of the young student.

Melancthon was present at the celebrated dispute between Carlostadt and Eckius at Leipsic, in the summer of 1519; and, though he represents himself as a mere hearer on this occasion, he became so much interested in the procedings, and so often offered suggestions to Carlostadt, that Eckius was induced to exclaim, with some warmth, 'Tace tu Philippe, ac tua studia cura, nec me perturba.' He afterwards wrote an account of this conference in a letter to a friend, which, falling into the hands of Eckius, produced from him a bitter rejoinder, which Melancthon answered in a small tract, written with so much acuteness, elegance, and candor, that it greatly promoted the cause of the reformers.

In the year 1520 he married Catharine Crappin, the daughter of a burgomaster of Wittemberg, with whom he lived in the most perfect harmony for thirty-seven years, and by whom he had two sons and two daughters. Both the for-

mer died young; the latter were married, the elder to George Sabinus, the younger to Caspar Peucer, an excellent man, who suffered much for maintaining the doctrines of the Reformation.—Melancthon's wife is said to have been a pattern to her sex for the simplicity and purity of her manners, and diligent domestic economy. Yet so great was their hospitality that their house was scarcely ever free from guests, and it seems to have been a maxim with them never to refuse a needy applicant. In addition to these serious deductions, as they may be justly accounted, from his very moderate income, the time of this great man was often severely taxed by the calls of persons soliciting his advice in their difficulties, his correction of literary productions, or his recommendations to others. For a considerable time he delivered his lectures on the Holy Scriptures without any salary; and, when the elector offered to settle on him a pension of 200 florins, he refused it, on the ground that he was unable to devote sufficient time and attention to the duty which he judged was incumbent upon him. When the elector Maurice urged him on this subject, and entreated him at least to ask some favor, he requested his dismission. He is said to have been materially assisted in his projects of benevolence by the faithful care of an affectionate domestic, to whom all the duties of provisioning his family were intrusted, and who, after faithfully discharging those duties and contributing to feed the streams of his charity for more than thirty years, died in the bosom of the family, regretted as a friend. The benevolence of Melancthon, however, was retired, and entirely devoid of ostentation; and, although mentioned by few writers, yet it is an undoubted fact that, when his purse was insufficient to answer the calls that were thus made on it, he would sometimes supply the deficiency by privately disposing of articles of domestic furniture.

Whatever he read or heard he quickly made his own; it is even asserted that he could retain, for the most part, the very words of the writer or speaker. In the midst of all these excellencies he was so modest that he never uttered his opinion without the most serious deliberation, and was ready to acknowledge any mistakes, into which he might have fallen, with the greatest simplicity. His good qualities, indeed, were so conspicuous, that the very enemies of that Reformation, of which he was so ardent a supporter, most readily acknowledged and extolled them.

The importance of so able a coadjutor in the good cause was very apparent, and none valued his assistance more than Luther. During his temporary confinement in the castle of Wartenburg, we find him thus expressing himself: 'The accounts which I receive of your abundant success in religion and learning during my absence rejoice my heart exceedingly, and very much diminish the miseries of separation. The circumstance of your going on so prosperously is peculiarly delightful to me, because it may serve to convince the wicked one, that, however he may rage and foam, his desires shall perish, and Christ will finish the work which he has begun.' While, however, Melancthon was so important an auxiliary to Luther in the great cause in which they were embarked, such was his constitutional timidity, that all the firmness of Luther was necessary to console and support him. Yet we never find him for a moment abandoning the post of duty. In the year 1521 the doctors of the Sorbonne attacked the Lutheran doctrines, in a violent pamphlet; to which Melancthon replied in a piece entitled Adversus Furiosum Parisiensium Theologastrorum Decretum pro Luthero Apologia. In this publication, he, with the keenest satire, exposes the folly of these monkish divines, showing that those very men who contended against Luther for opposing the fathers, were themselves the most diametrically opposed to them. He published another piece this same year against Thomas Placentinus, or Emset, who had attacked Luther on the ground of his secession from the church. A piece which excited the greatest attention, however, at this time, was that which he published under the title of Loci Communes Theologici. It was translated and extensively read in France and Italy, particularly in Venice, till a monk, who had seen it in its German dress denounced it to the inquisitors, and had it suppressed. The author in this publication gives a summary of Christian doctrine, which is at once both lucid and Scriptural, and calculated to make any one, according to Luther, who has become master of it, in conjunction with a thorough knowledge of the Scriptures, a divine against whom neither the devil nor any heretic can be able to stand. In this eventful year also Melancthon was called to take a conspicuous part in the abolition of private masses. The Augustinian Friars at Wittemburg had attempted this in Luther's absence, and the elector, alarmed at the measure, had sent one of his counsellors to remonstrate with them. Our reformer was chosen, in conjunction with five others, to enquire into this matter, and so thoroughly were they convinced of the propriety of the step, that they urged the prince to enforce it throughout his dominions. Melancthon gave full proof in this discussion of his deep acquaintance with the Scriptures and the history of the purer ages of the church, as well as of the firmness with which he could resist corruption; until the elector was finally induced to wink at these innovations, though he did not publicly countenance them.

In the early part of the year 1522 the subject of this memoir was engaged in a conference with Stubner and others of the Anabaptists, see that article. The piety of some of these sectaries and the sufferings they had endured on account of their opinions, made a considerable impression upon his mind, and led him to treat them with more kindness than was shown to them by Luther. The latter indeed readily perceived the dangerous issue of their more prominent opinions.

It has been already mentioned that Melancthon was one of his coadjutors in the translation of the Holy Scriptures (see article Luther), and not a little of the correctness and fidelity with which this work was executed is to be attributed to his labors. His extensive acquaintance with the original languages eminently fitted him for

this work, and no one could feel more than he did its importance to the cause of the reformation. We find him also employed about this time in writing a valuable Commentary on the Epistle of Paul to the Romans, which was not, however, published till the year 1540. In the dedication to Philip of Hesse will be found a clear statement of the author's sentiments on the most important articles of Christian doctrine, as well as a consistent view of the whole train of the apostle's reasoning, while his criticisms are most valuable. In the month of May 1525 he assisted at the funeral of the lamented Frederick, elector of Saxony, and delivered an oration, which affords a high but not unmerited encomium on that prince, the greatest of all the human supporters of the reformed religion of this period.

So highly was Melancthon esteemed at this time, even by the enemies of the Reformation, that not a few attempts were made by the catholic party to draw him over to themselves. That of the celebrated Erasmus is the most remarkable, both because it equally illustrates the dishonest adherence of that eminently learned man to a cause, the weakness and wickedness of which he often exposed in his works, and the steady adherence of our reformer to those opinions which upon the full conviction of his conscience he had adopted. Erasmus used every effort to shake him, by hinting to him the wishes of some of the highest dignitaries in the church that Melancthon would come over to them, and his regret that he had not devoted his great powers to literature alone. The language of Melancthon in reply to these insinuations is decided and noble: 'For my own part,' says he, 'I cannot with a safe conscience condemn the sentiments of Luther, however I may be charged with folly or superstition, that does not weigh with me. But I would oppose them strenuously, if the Scriptures were on the other side; most certainly I shall never change my sentiments from a regard to human authority, or from the dread of disgrace.' We are also told that cardinal Campeggio used his most strenuous endeavours to bring over Melancthon to the orthodox party; but he met with no better success.

It was in consequence of an accidental meeting between our reformer, while on a journey, and Philip the landgrave of Hesse, that the latter first made those enquiries into the nature of the Reformed doctrine which resulted in his adopting it. In the mean time the cause of religion and learning continued to advance in Saxony, and in the latter part of the year 1525, by the permission of the elector, Melancthon repaired to Nuremberg to arrange for the senate the plan of an academical institution there. On the occasion of its opening we find him delivering an oration, in which he complains in very severe terms of the neglect of learning, which marked the priesthood of the day, and animates the senate to proceed in the good work in which they had engaged, as the most seasonable remedy for that evil. So great was the admiration of him excited at Nuremberg, that he was invited to fill a professor's chair in the new university; this, however, he was too warmly attached to Wittemburg to accept: but he continued to correspond with those who had the management of its affairs; and that even at a time when his numerous engagements were seriously injurious to his health.

In the year 1526, when it was judged advisable by the elector of Saxony to present a memorial at the diet of Spires, Melancthon was required by that prince to draw it up, which he accomplished in a very satisfactory manner; refuting the chief objections of the papists to the reformed doctrine; and citing in particular the commandments of Christ and the examples contained in the Scriptures to demonstrate that justification by faith is the great truth of the word of God, which must be maintained at the risk of the severest persecution. He enters upon several other topics with equal faithfulness and power, insisting that the reformers had separated from the Romish church not from the love of schism, but because they were impelled to that separation by the obedience due to the Scriptures and to God. The result of this appeal was highly advantageous, as will be seen in the article Reformation. In the mean time our reformer was called upon to advise the landgrave of Hesse as to the promotion of the Reformation in his states, and in preparing for publication a directory of doctrine and practice. In this work the papists alledged that Melancthon advocated different sentiments to those of Luther, and loudly exulted in the circumstance; nothing, however, was more unfounded, and Luther himself treated the charge with the utmost contempt. A more serious vexation occurred to the author in the conduct of one of his fellow-laborers. In speaking of the law Melancthon had urged the inculcating a spirit of contrition in order to obtain the remission of sins; at this John Agricola was so offended, that a breach took place between him and Melancthon, which was with difficulty made up by the interference of the elector. Agricola afterwards became the founder of a sect called the Antinomians; see Agricola and Antinomians.

Melancthon attended at the second diet of Spires in the year 1529, and was during the meeting the means of preserving the liberty, if not the life, of Simon Grynæus, professor of Greek in the university of Heidelburg. The latter had engaged in an argument with Faber, bishop of Vienna, which induced that crafty prelate to adopt means for removing him by force from the diet. While Grynæus was at supper with his friends, Melancthon, who was of the party, was called out to speak with an old man of singular appearance, who advised that Grynæus should be sent to a place of safety, as some messengers from the king, at the instigation of Faber, were coming to seize him. Grynæus was accordingly sent away, and almost immediately after the messenger arrived: the old man being never afterwards seen or heard of, the warning given was regarded as nothing less than a divine interposition. Melancthon was, during the sitting of this diet, harassed with great anxiety; the interdiction of every innovation in religion, and the solemn protest of the reformed princes, which then took place, made it a scene of great interest; and he and Luther were constantly looked up to

as advisers in these trying circumstances. At the same time the agitation of the sacramental controversy caused them no small grief, especially as it tended to separate them from those whom they could not but regard as brethren. In this year Melancthon published a Commentary on the Epistle to the Colossians, to which Luther wrote a preface, speaking highly of it and preferring it to his own works.

In 1530 we find Melancthon employed to draw up the celebrated confession of Augsburg; and such was the effect produced, that several of the Catholics acknowledged it could not be answered from the Scriptures; when an answer was at length prepared, the emperor, as if aware of its weakness on other grounds, declared authoritatively, that those were his sentiments, and he would no longer tolerate any who did not adopt them. The Apology for the Augsburg Confession was also written by our reformer, and with the same mixture of firmness and suavity: these qualities indeed were so conspicuous, as well as his great talents, at the conferences wnich were now frequently held with the Romish party, that they made several efforts to gain him over, but, as before, he stood firm in his attachment to the truth. It was at this momentous crisis, when the decree of the diet had been published, asserting the doctrines of popery, and condemning the Protestants, that the courage of Melancthon and his confidence in Divine assistance displayed themselves in a striking manner. While he and his friends were anxiously deliberating upon the best measures to be pursued, he was suddenly called out of the room. Some of the elders of the reformed churches had brought their friends and families to pray for and encourage the minds of their leaders, and even the children were seen engaged in prayer on their behalf. Encouraged by this scene he returned to his friends with so cheerful a countenance, that Luther rallied him upon it, and asked what had produced so sudden a change. 'O,' said Melancthon, 'I have seen our noble protectors, and such as, I will venture to say, will prove invincible against every foe.' 'And, pray,' said Luther, 'who are they?' 'They are the wives of our parishioners and their little children,' rejoined his colleague, 'whose prayers I have just witnessed—prayers which, I am satisfied, our God will hear.'

In the month of August, 1532, Melancthon was called to the office of delivering an oration at the funeral of the elector John, whom he deservedly styles a pious, firm, and peaceful prince, the father of his people. We afterwards find him delivering his decided opinion on the attempt of the pope and his nuncio to fix the meeting of a general council in Italy. In consequence of this advice the nuncio was informed, that, the controversy having been principally carried on in Germany, it was proper that the council should be assembled there. Two years after Melancthon was requested to undertake a journey, in order to confer with Bucer on the sacramental controversy; and in the same year his accustomed candor and meekness were displayed in a conference with certain of the Roman Catholic party, appointed by the archduke Ferdinand and duke George.

So universal was the fame of cur reformer that in the month of June, 1535, he received a pressing invitation from Francis I. of France, to visit his dominions, in order to discuss the subjects of difference between the Protestants and the papal see. Some of his friends (among whom was Luther) urged his compliance; but it was well perhaps for the Protestant cause that some impediments were interposed, as there is more than a doubt of the sincerity of the French court:—about this time, in consequence of some indiscreet reflections of the Protestants on the Romish clergy, six Lutherans were condemned to death by the parliament of that country, and actually suffered. The elector excused himself to the king for not sending him, on the plea that his services were more than ever necessary at home, as the academy at Wittemburg had been scattered by a pestilential disorder. Melancthon, however, wrote a small work on the best means of settling religious controversies, and sent it to the king. About the same time also Henry VIII. of England, having sent Dr. Barnes to consult the Saxon divines respecting his divorce from Catherine of Arragon, urged Melancthon to visit this country. Henry, it appears, was not a little jealous of his proposed visit to France, and made use of every means to draw him over to England. But our reformer, notwithstanding his own wish and that of Luther, that he should comply with this request, was obliged by the elector to refuse; and could only send to his royal correspondent letters of advice, and a copy of his Commentary on the Romans. In return, the latter wrote him a letter, expressing his approbation of his zeal in defence of religion, and presented him with 200 crowns, a large sum in those days. Henry's chief object in these negociations being to procure the sanction of his divorce from the Saxon divines, and neither Luther nor Melancthon being able to concur in it, the correspondence soon dropped. Our reformer, however, by this means became acquainted with some of the most celebrated leaders of the Reformation in England, particularly archbishop Cranmer.

In a journey undertaken for the benefit of his health, in 1536, Melancthon rendered essential service to the university of Tubingen by his advice relative to its religious and literary management. He also wrote at this time a treatise against the fanatical Anabaptists, who had produced great disturbances among the lower orders. Soon after his return home another conference was held between the Saxon and Swiss divines, upon the sacramentarian controversy, and he was appointed to draw up a formula on the subject; which all parties agreed in signing.

Melancthon was now (February, 1537) called upon to take a leading part at the meeting of Smalcald, held by the confederate Protestant princes, to deliberate on the propriety of attending the council, appointed by pope Paul III. for the 27th of May following; and incurred no little odium on account of his willingness to make concessions to the Catholics, for the sake of peace. But his work composed for this occasion, on the supremacy of the pope and the authority of bishops, manifested his firmness on essential points. He also wrote tne letters tha

passed between the princes and the king of France on the subject of this council. It was his pen, indeed, that was at this time used in drawing up almost all the authorised documents of the Protestant princes. A further attempt was made this year by the pope, through the means of cardinal Sadolet, to conciliate Melancthon; and Henry VIII. applied again for a deputation of the Saxon divines, and especially for a visit from our reformer; he was, however, too much occupied with other concerns; year after year passed away, and the journey was never accomplished. One of his letters to the king at this time boldly exposes those errors of popery which he still retained in his system, and which the English bishops greatly contributed to uphold. In 1540 he drew up a new and excellent defence of the Reformers, and soon after, while on his way to the diet at Spires, was taken so ill, that he appeared to Luther to be on the point of death. Alarmed at this, the latter broke out into the most ardent supplications, and then, turning to the patient, confidently assured him that he should not die; that God would raise him up. Strange as it may appear, while he was speaking, Melancthon evidently revived, and was soon after restored to health: he himself even says, 'I must have died, if Luther had not recalled me from the gates of death.'

At the conference which opened in the month of January 1541, at Worms, Melancthon was engaged in a dispute with Eckius; but, at the end of the third day, the emperor ordered his agent Granville to break up the meeting, appointing another at Ratisbon early in the spring. On his journey thither Melancthon, being overturned, dislocated the wrist of his right hand, and he never afterwards recovered the full use of it. In this meeting he again had a long debate with Eckius, during which his opponent, having brought forward some perplexing sophism, Melancthon paused to consider, and then said, 'I will give you an answer to morrow.' Eckius replied, 'But there is no honor in that: why cannot you answer me immediately.' 'My good doctor,' said Melancthon, 'I am not seeking my own glory in this business, but truth: I say, God willing, you shall have an answer to-morrow.' In the year 1542 we find him assisting at the ordination of a Protestant bishop, at Naumburg; and, early in the next year, he was engaged in a correspondence with the prince archbishop of Cologne, about the introduction of the reformed religion into his dominions. He visited Cologne, and, though the object proposed was not fully accomplished, much good was done, and the city of Hildesheim, in particular, embraced the Protestant doctrine. At this period many private and public trials oppressed his mind: the improper behaviour of one of his sons-in-law, and the death of his friend Valerius Cordus, the renewal of the sacramental controversy, in which Luther manifested unjustifiable violence of language, and the miserable state of the Protestants in France, all conspired to embitter his declining life. In 1545 he drew up a plan of proceeding for the elector palatine, who wished to introduce the Protestant doctrine into his country; and soon after assisted at the episcopal ordination of George, prince of Anhalt, who had devoted himself to the ministry of the gospel.

Melancthon, however, seems justly to have regarded the death of Luther, in 1546, as the most afflictive event that ever befel him. He expressed his feelings most powerfully in the affectionate and able oration delivered at the funeral of this great man: for not less than twenty-eight years had they lived and labored together in the same cause, and though they differred in some few of their sentiments, and were in many respects of very opposite dispositions, their harmony seems never to have been interrupted. In the month of November the university of Wittemburg being dissolved for a short time, in consequence of the war between the emperor and the Protestant princes, Melancthon retired, with his wife and family, to Yerbst, in Anhalt. Here he received repeated offers of a professor's chair in the university of Jena, but he could not bring his mind to forsake Wittemburg, and, in less than a twelvemonth, recommenced his lectures. In this year, also, the famous temporary rule of faith and worship, called the Interim, was published at Augsburg by order of the emperor Charles V., and afterwards enforced by the sword. To this document Melancthon replied, exposing its errors, and setting forth its miserable defects: his work was immediately translated into English. In the month of January 1552 he set out on his journey to the council of Trent, but soon was obliged to return in consequence of a war breaking out between the elector of Saxony and the emperor.

Melancthon now continued in his usual occupation at Wittemburg, occasionally attending different conferences, and composing most of the official documents that the Protestants promulgated. Truth compels us to add, that he was found approving the conduct of Calvin in the persecution of the miserable Servetus, the only apology for which is, that the principles of religious liberty were ill-understood by all parties; and that the reformers themselves were scarcely delivered, at this time, from the thraldom of a church in which persecution was professed and vindicated. The care of all the Protestant churches may be said now to have devolved on Melancthon, and he had frequently to meet his popish adversaries on the most important subjects. The last conference he attended was in 1557, at Worms; when the right of private judgment in matters of religion was discussed, and he manfully maintained the great principle of the Reformation, that the only authority to which human reason ought implicitly to submit, in religious concerns, is the infallible word of God. He then visited Heidelburg at the request of the elector palatine; and while there, surrounded by his friends, received the painful tidings of the death of his wife. He was now, in a great measure, weaned from the world, and, after a life of useful and even splendid public labors, closed his mortal career on the 19th of April 1560, in the sixty-fourth year of his age. He was interred at Wittemburg near his friend and associate Martin Luther. 'Nature,' says one of his biographers, 'had given him a peaceable temper,—

which was not altogether in accordance with the times in which he lived: his moderation often only served as his cross. He was like a lamb in the midst of wolves; nobody liked his mildness; it looked as if he were lukewarm.' The following is an epitaph he composed on himself:—

Iste brevis tumulus miseri tenet ossa Philippi,
Quis, qualis fuerit nescio, talis erat.

MELANIPPIDES, a Greek poet, who flourished about A.A.C. 520 His grandson, of the same name, flourished about sixty years after, at the court of Perdiccas II. of Macedonia. Some fragments of their poetry are extant.

MELAS (M. de), a modern Austrian general, who served with distinction against the French republic. In 1793 and 1794 he was a major-general, and then a lieutenant field-marshal on the Sambre. He was removed in 1795 to the army of the Rhine; and, in March 1796, to that of Italy. In 1799 he was at the head of the Austrian army, acting in concert with Suwarrow. He distinguished himself at Cassano, and was present at the battles of Trebia and Novi; he beat Championnet at Genola, November 3d, and took Coni. In 1809, however, he lost the battle of Marengo; but, though his conduct was censured, he was afterwards appointed commander in Bohemia. In 1806 he presided at the court of enquiry into the behaviour of general Mack at Ulm. Melas died at Prague in 1807.

MELASSO, a large town of Anatolia, the ancient Mylasa, and formerly so adorned with public buildings as to originate the story of the crier, who, on entering the market-place, instead of saying Hear, ye people, called out, Hear, ye temples. It is situated in a fertile plain; but the modern houses are mean. It is eighty miles south of Smyrna.

MELASTOMA, in botany, the American gooseberry tree, a genus of the monogynia order, and decandria class of plants; natural order seventeenth, calycanthemæ: CAL. quinquefid and campanulated; petals five, inserted into the calyx: BERRY quinquelocular, and wrapped in the calyx. There are many species, all natives of the warm parts of America, and very beautiful, from the variegation of their leaves. Most of them are of two different colors on their surfaces; the under side being either white, gold-colored, or russet, and their upper parts of different shades of green; so that they make a fine appearance in the hot-house all the year round. There are few of these plants in the European gardens, from the difficulty of bringing over growing plants from the West Indies; and the seeds being small, when taken out from the pulp of their fruits, rarely succeed. The best way is to have the entire fruits put up in dry sand as soon as they are ripe, and forwarded by the quickest conveyance to Britain. They should be taken out as soon as they arrive, and the seeds sown in pots of light earth, and plunged into a moderate hot-bed of tanner's bark. When the plants come up, and are fit to be removed, they must each be planted in a small pot, and plunged into the tan-bed; and afterwards treated as other exotic plants.

MELAZZO, or MILAZZO (the ancient Mylæ), a sea-port town of the north coast of Sicily, in the Val di Demona. It is built on a promontory, which has a good road on each side, and a well-sheltered capacious bay. The town, which is ill-built, is divided into two parts: the one on the promontory being strongly fortified, and the other at the harbour, near the bottom of the bay. Neither contains any buildings of note. The trade chiefly consists in the export of wine, olives, and olive oil, to Marseilles, Leghorn, and Genoa. The tunny fishery is also considerable. The neighbourhood, covered with villages and groves of olives and orange trees, bounded by the mountains of Pelorus, exhibits a most picturesque scene. Population 6000. Twenty miles west of Messina, and 100 east of Palermo.

MELCHIOR (Adam), a German biographer, born at Grotkaw, in Silesia, and educated at the college of Brieg. He was a Calvinist; was made rector of a college at Heidelberg, and wrote several works, particularly five volumes of the Lives of Illustrious Men, 1615—1620. He died in 1622.

MELCHISEDEC, or MELCHIZEDEC, king of Salem, and priest of the Most High. The scripture tells us nothing either of his father, mother, genealogy, birth, or death. And in this sense St. Paul says, he was a figure of Jesus Christ, 'who is a priest for ever, after the order of Melchisedec,' and not after the order of Aaron, whose origin, life, and death, are known. When Abraham returned from his victory over the four confederate kings, Gen. xiv. 17—19, &c., Melchisedec came to meet him, at the valley of Saveh; presented him with a refreshment of bread and wine, and blessed him, and Abraham offered him the tythes of all the spoils. After this no mention is made of Melchisedec; only the Psalmist (cx. 4), speaking of the Messiah, says, 'Thou art a priest for ever after the order of Melchisedec.' St. Paul, in his epistle to the Hebrews (vii. 6—10), unfolds the mystery. A great number of difficulties, however, have been started respecting the person of Melchisedec. St. Jerome thought that Salem, of which Melchisedec was king, was not Jerusalem, but the city of Salem, near Scythopolis, where they still pretended to show the ruins of his palace. The greatness and extent of these ruins are, he says, a proof of the magnificence of this ancient building. He thinks it was at this Salem, or Shelem, that Jacob arrived after his passage over Jordan, on his return from Mesopotamia. (Gen. xxxiii. 18). Some believe that Salem, where Melchisedec reigned, is the same as Salem mentioned by John, chap. iii. 23. Various names have been invented for the parents of Melchisedec. But it is generally agreed by the learned that when the apostle says (Heb. vii. 3), he was 'without father and without mother,' &c., no more is meant than that he derived his priesthood from no ancestral right, and handed it down to no posterity, or order of men. Nevertheless, some have taken St. Paul's words literally, and contend that he was not of human origin. Origen and Didymus took him to be an angel. The Arabic Catena, upon the ninth chapter of Genesis, makes Melchisedec to b

descended from Shem by his father, and from Japheth by his mother. Cedrenus and others derive Melchisedec from an Egyptian stock. They say his father was called Sidon, and was the founder of Sidon, the capital of Phœnicia. The Jews and Samaritans believed Melchisedec to be the same with the patriarch Shem; which opinion has been followed by many modern writers. M. Jurieu endeavoured to prove that he is the same as Ham. Peter Cunæus and du Moulin asserted that Melchisedec, who appeared to Abraham, was the son of God, and the patriarch worshipped him, and acknowledged him for the Messiah. We shall only add one opinion more concerning Melchisedec. The learned Heidegger supposes a two-fold Melchisedec; the one historical, of whom Moses gives an account in Gen. xiv. that he was king as well as high-priest of Jerusalem; the other allegorical, whom St. Paul describes, and this is Jesus Christ. Numberless other fables have been invented of Melchisedec, which are totally unworthy of notice.

MELCHISEDECIANS, a sect of heretics, who rose in the beginning of the third century, and affirmed that Melchisedec was not a man, but a heavenly power, superior to Jesus Christ: for Melchisedec, they said, was the intercessor and mediator of the angels, but Jesus Christ was so only for men, and his priesthood only a copy of that of Melchisedec, who was the Holy Ghost.

MELCHITES, in church history, the name given to the Syriac and Egyptian Christians. The Melchites, excepting some few points of little or no importance, which relate only to ceremonies and ecclesiastical discipline, are in every respect professed Greeks; but they are governed by a particular patriarch, who resides at Damas, and assumes the title of patriarch of Antioch. They celebrate mass in the Arabian language. The religious among the Melchites follow the rule of St. Basil, the common rule of all the Greek monks. They have four fine convents, about a day's journey from Damas, and never go out of the cloister.

MELCOMBE Regis, a town of Dorsetshire, 127 miles from London, at the mouth of the Wey, by which it is separated from Weymouth. It appears from the name to have been anciently the king's demesne, and from the records to have paid quit-rent to the crown, after the time of king Edward I. till it was bought off by the inhabitants before they were united to Weymouth. It lies on the north side of the haven, on a peninsula, surrounded by the sea on all sides except the north. The streets are broad and well paved, and many of the houses large and high. It sent members to parliament in the reign of Edward I. before Weymouth had that privilege. It was appointed a staple in the reign of Edward III. In the next reign the French burnt it; and it was thereby rendered so desolate, that the inhabitants obtained a discharge from customs. In the reign of Henry VI. its privileges, as a port, were removed to Pool; but in that of queen Elizabeth they were restored by act of parliament, which was confirmed by king James's reign, on condition that Melcombe and Weymouth should make but one corporation and borough, and enjoy their privileges in common; and to this was owing the flourishing state of both. In the two reigns last mentioned a wooden bridge with seventeen arches was built from hence to Weymouth; to which, as well as its church, the chief contributors were citizens of London. Upon its decay it was rebuilt in 1770. It has a good market place and town hall, to which the members of the corporation of Weymouth come to attend public business. For several years past the sea has retired from it on the east, the priory formerly being bounded by the sea; but there is now a street beyond it, from which it is several paces to the high water mark. The priory was situated in the east part of the town, in Maiden Street, whose site occupied about an acre, now covered with tenements. Near it are the remains of an ancient nunnery. It has three meeting-houses, and a work-house for the poor. The church, which is in the middle of the town, has a wooden turret for a bell. It was rebuilt in 1605, and made parochial; and is a handsome fabric, with a beautiful altar piece, painted and given by Sir James Thornhill. The port, which generally goes by the name of Weymouth, is the best frequented in the county, and is defended by Sandford and Portland castles. The markets for both towns are on Tuesday and Friday. Melcombe Regis is bigger, more thriving, and populous than Weymouth. The united corporation consists of a mayor, recorder, two bailiffs, an uncertain number of aldermen, and twenty-four capital burgesses. Whoever has been a mayor is ever after an alderman. They send two burgesses to parliament, who are elected by freeholders, whether they reside or not; and the number of inhabitants is 8200. Every elector has the privilege of voting for two persons, who, when chosen, are returned, in conjoint indentures, as the burgesses of Weymouth and the burgesses of Melcombe Regis. Melcombe lies eight miles south of Dorchester, and 127 W.S.W. of London. See Weymouth.

MELEAGER, in fabulous history, a celebrated hero, son of Œneus, king of Ætolia, by Althæa, daughter of Thestius. The Parcæ were present at his birth, and predicted his future greatness. Clotho predicted that he would be brave and courageous; Lachesis foretold his uncommon strength and valor; and Atropos said that he should live as long as that fire-brand which was on the fire remained entire and unconsumed. Althæa no sooner heard this, than she snatched the stick from the fire, and kept it with the most jealous care, to preserve the life of her son. The fame of Meleager increased with his years; he signalised himself in the Argonautic expedition, and afterwards delivered his country from the neighbouring inhabitants, who made war against his father at the instigation of Diana, whose altars Œneus had neglected. But Diana punished the negligence of Œneus by a greater calamity. She sent a huge wild boar, which laid waste all the country, and seemed invincible, on account of its immense size. All the neighbouring princes assembled to destroy this terrible animal. Among these, besides Meleager, were Idas and Lynceus, sons of Aphareus, Dryas son of Mars, Castor and Pollux, Piri-

thous son of Ixion, Theseus, Anceus, and Cepheus, sons of Lycurgus, Admetus son of Pheres, Jason, Peleus and Telamon sons of Æacus, Iphicles son of Amphitryon, Eurytryon son of Actor, Atalanta daughter of Schœneus, Iolaus the friend of Hercules, the sons of Thestius, Amphiarus son of Oileus, Protheus, Cometes, the brothers of Althæa, Hippothous son of Cercyon, Leucippus, Adrastus, Ceneus, Phileus, Echion, Lelex, Phœnix son of Amyntor, Panopeus, Hyleus, Hippasus, Nestor, Menœtius the father of Patroclus, Amphicides, Laertes the father of Ulysses, and the four sons of Hippocoon. This troop of heroes attacked the bear, and it was at last killed by Meleager. The conqueror gave the skin and the head to Atalanta, who had first wounded the animal. This irritated the rest, and particularly Toxeus and Plexippus the brothers of Althæa, and they endeavoured to rob Atalanta of the honorable present. Meleager defended her, and killed his uncles. Meantime the news of this celebrated conquest had already reached Calydon, and Althæa went to the temple to return thanks for the victory which her son had gained; but, being informed that her brothers had been killed by Meleager, she, in the moment of resentment, threw into the fire the fatal stick on which her son's life depended, and Meleager died as soon as it was consumed.

Meleager, a Greek poet, the son of Eucrates, was born at Seleucia in Syria, and flourished under Seleucus VI., the last king of Syria. He was educated at Tyre; and he died in the island of Coos, anciently called Merope. He there composed the Greek epigrams called Anthologia, which Planudes arranged in 1380.

MELEAGRIS, in ornithology, the turkey; a genus of birds belonging to the order of gallinæ. The head is covered with spongy caruncles, and there is likewise a membranaceous longitudinal caruncle on the throat.

M. gallopavo, the turkey of Ray, has a caruncle both on the head and throat; and the breast of the male is bearded or tufted. He lives upon grain and insects; when angry blows up his breast, spreads and erects his feathers, relaxes the caruncle on the forehead, and the naked parts of the face and neck become intensely red. Barbot informs us that very few turkeys are to be met with in Guinea, and those only in the hands of the chiefs of the European forts; the negroes declining to breed any, on account of their tenderness, which proves them not to be natives of that climate. Neither is that bird a native of Asia; the first that were seen in Persia were brought from Venice by some Armenian merchants. They are bred in Ceylon, but not found wild. It is the commonest wild fowl in North America, where they are often met with by hundreds in a flock. In the day time they frequent the woods, where they feed on acorns; and return at night to the swamps to roost on the trees. They are often taken by dogs, though they run fast for a time; but, the dogs persisting, the birds grow fatigued, and take to the highest trees, where they are shot one after another, if within gunshot. Turkeys were first seen in France in the reign of Francis I., and in England in that of Henry VIII. By the date of these reigns, the first turkeys must have been brought from Mexico, about A. D. 1521. Ælian mentions a bird found in India, which some writers have suspected to be the turkey; but Pennant concludes with Gesner, that it was either the peacock, or some bird of that genus. The hen begins to lay early in spring, and often produces a great number of eggs, which are white, marked with reddish or yellow spots, or rather freckles. She sits well, and is careful of her young; of which in this climate she often has from fourteen to seventeen for one brood; but she scarcely ever sits more than once in a season, except allured by putting fresh eggs under her as soon as the first set are hatched; for, as she is a close sitter, she will willingly remain two months on the nest, though this greatly injures her. Turkeys are bred in quantities in some northern counties of England, and are driven up to London in autumn for sale, in flocks of several hundreds, collected from the cottages about Norfolk, Suffolk, &c., the inhabitants of which attend carefully to them, by making them part of their family during the breeding season. It is curious to see with what facility the drivers manage them, by a bit of red rag fastened to a stick, which, from their antipathy to the color, has the same effect as a scourge to a quadruped. There are several varieties. The most common is dark gray, inclining to black, or barred dusky white and black. There is also a beautiful variety, of a fine deep copper color, with the greater quills pure white, and the tail of a dirty white. A variety with a pure-white plumage is also now frequent, and appears very beautiful. It was once esteemed a great rarity, and supposed originally to have arisen in Holland. In the Leverian museum is also a common turkey, with a large tuft of feathers on its head, much resembling one figured by Albin.

MELETIANS, in church history, a considerable party who adhered to the cause of Meletius, bishop of Lycopolis, in Upper Egypt, after he was deposed, about A. D. 366, by Peter, bishop of Alexandria, under the charge of having sacrificed to the gods, and been guilty of other heinous crimes; though Epiphanius makes his only failing to have been an excessive severity against the lapsed. This dispute, which was at first a personal difference between Meletius and Peter, became a religious controversy; and the Meletian party subsisted in the fifth century, but was condemned by the first council of Nice.

MELIA, Azaderach, or the bead-tree, in botany, a genus of the monogynia order and decandria class of plants; natural order twenty-third tribilatæ: cal. quinquedentated; the petals five: the nectarium cylindrical, as long as the corolla, with its mouth ten-toothed; the fruit is a plum with a quinquelocular kernel. There are three species, all exotic trees of the Indies, rising nearly twenty feet high, adorned with large pinnated leaves, and clusters of pentapetalous flowers. They are all propagated by seeds sown on hot-beds.

MELIANTHUS, honey-flower, in botany, a genus of the angiospermia order, and didynamia class of plants: cal. pentaphyllous, with the lowermost leaf gibbous: there are four petals, with the nectarium under the lowest: caps. quadrilocular.

1. M. major has a thick, ligneous, spreading root; many upright, ligneous, durable stalks, rising six or eight feet high; garnished with large pinnated leaves of four or five pair of serrated lobes, terminated by an odd one; and, from the sides and tops of the stalks, long spikes of chocolate-colored flowers.

2. M. minor has a root like the former; upright, ligneous, soft, durable stalks, rising four or five feet high; garnished with smaller pinnated leaves; and, from the sides and ends of the branches, long, loose, pendulous bunches of flowers tinged with green, saffron color, and red. Both species flower about June, but rarely produce seeds in this country. They are very ornamental, both in foliage and flower, and merit admittance in every collection. They are easily propagated by suckers and cuttings. They thrive best in a dry soil, and a sheltered warm exposure.

MELIBOEA, in ancient geography, an island of Syria, at the mouth of the Orontes; which forms a spreading lake round it. It was famous for its purple dye; and is supposed to have been originally a Thessalian colony. Hence Lucretius's epithet, Thessalicus.

MELICA, rope-grass, a genus of the digynia order, and triandria class of plants: CAL. bivalved, biflorous, with an embryo of a flower betwixt the two florets. There are many species, of which the most remarkable are,

M. altissima, and ciliaca, which thrive on the most barren hills, and are much relished by cattle. M. cerulea affords an excellent substitute for hair in the manufacture of brooms. M. nutans is a native of several parts of Britain and the adjacent islands; and the inhabitants of some of the western islands make ropes of it for fishing-nets, as it will bear the water long without rotting.

MELICE'RIS, *n. s.* Gr. μελικηρις.

Meliceris is a tumour inclosed in a cystis, and consisting of matter like honey. If the matter resembles milk curds, the tumour is called atheroma; if like honey, *meliceris*: and if composed of fat, or a suety substance, steatoma. *Sharp.*

MELICERTA, MELICERTES, or MELICERTUS, in mythology, a son of Athamas and Ino. His mother saved him from his father's fury, who prepared to dash him against a wall, as he had done his brother Learchus. The mother was so terrified that she threw herself into the sea with Melicerta in her arms. Neptune had compassion on the misfortunes of Ino and her son. He changed them both into sea deities. Ino was called Leucothoë or Matuta; and Melicerta was called by the Greeks Palemon, and by the Latins Portumnus. Some suppose that the Isthmian games were instituted in honor of Melicerta.

MELINDA, a kingdom on the east coast of Africa, situated between lat. 3° and 4° S., though there is great disagreement among geographers as to its extent, and it is altogether but little known. The coasts here are very dangerous; being full of rocks and shelves, and the sea at various seasons very liable to tempests. The interior is said to be for the most part rich and fertile; producing almost all the necessaries of life, except wheat and rice, both of which are brought thither from Cambaya and other parts potatoes are here fine, large, and in great plenty It also abounds with great variety of fruit-trees, roots, plants, and other esculents, and with melons of fine taste. There is also great plenty of venison, game, oxen, sheep, hens, geese, and other poultry, &c., and one breed of sheep, whose tails weigh between thirty and forty pounds. Here Vasco de Gama, having doubled the Cape, met with a hospitable reception, and was supplied with pilots to conduct him to Malabar. Cabral and several of his successors also met with friendly treatment on this coast. The Portuguese, however, as their power extended, became too haughty to be tolerated even by friendly powers. A quarrel arose: Melinda was taken and destroyed by them, and, when it was rebuilt, became one of their tributaries; till about 1698, when it was wrested from them by the Arabs.

Melinda, the capital, is a large handsome town, having houses built of stone, and many of them richly furnished. The numerous mosques give it a splendid appearance from the sea; but most of the churches and buildings erected by the Portuguese are in ruins. At the mouth of the Quillimany it has a good port, but it is difficult of access from shoals. Still it is the seat of a very considerable trade with the Red Sea, Persia, and the northern parts of India. The exports are gold, ivory, copper, wax, and drugs; in exchange for which they receive silks, cottons, linen cloths, and European goods.

MELINUM, in natural history, the name of an earth famous in the earliest ages of painting, being the only white of the great painters of antiquity; and, according to Pliny's account, one of the three colors with which alone they performed all their works. It is a fine, white, marly earth, of a very compact texture, yet remarkably light; a sort of texture which must render any earth fit for the painter's use that is of a proper color. It is often found forming a stratum in the earth, lying immediately under the vegetable mould. It is of a very smooth, but not glossy surface; is very soft to the touch; adheres firmly to the tongue; is easily broken between the fingers; and stains the skin in handling. It melts readily in the mouth, and is perfectly fine; leaving not the least grittiness between the teeth; thrown into water, it makes a loud bubbling and hissing noise, and moulders away into a fine powder. It does not ferment with acids; and suffers no change in the fire. These are the characters by which the melinum of the ancients is distinguished from all other white earths. It is still found in the same place from which the painters of old had it, viz. the isle of Milo or Melos, whence it had its name; and is common in most of the adjacent islands.

ME'LIORATE, *v. a.*
MELIORA'TION, *n. s.*
MELIOR'ITY.
Fr. *ameliorer*; Latin *melior*, better. To make better, or happier; improve. Melioration is the act or habit of improving. Meliority, state of being better.

Grafting *meliorates* the fruit; so that the nourishment is better prepared in the stock than in the crude earth. *Bacon.*

For the *melioration* of musick there is yet much left to try. *Id.*

Men incline unto them which are softest, and least in their way, in despight of them that hold them hardest to it; so that this colour of *meliority* and pre-eminence is a sign of weakness. *Bacon.*

But when we graft our buds inoculate,
Nature by art we nobly *meliorate*. *Denham.*

Castration serves to *meliorate* the flesh of those beasts that suffer it. *Graunt.*

Much labour is required in trees;
Well must the ground be digged, and better dressed,
New soil to make, and *meliorate* the rest. *Dryden.*

A man ought by no means to think that he should be able so much as to alter or *meliorate* the humour of an ungrateful person by any acts of kindness. *South.*

The order and beauty of the inanimate parts of the world, the discernible ends of them, the *meliority* above what was necessary to be, do evince, by a reflex argument, that it is the workmanship, not of blind mechanism, but of an intelligent and benign agent. *Bentley.*

Past indiscretion is a venial crime,
And if the youth, unmellowed yet by time,
Bore on his branch luxuriant then and rude
Fruits of a blighted size, austere and crude,
Maturer years shall happier stores produce,
And *meliorate* the well-concocted juice. *Cowper.*

MELIPILLA, a town and province of Chili, bounded on the north by Quillota, on the east by Santiago, on the south by the river Maypo, which divides it from Rancagua, and on the west by the sea. The province, abounding with wine and grain, is of small extent upon the sea, but is about twenty-five leagues from east to west. Its rivers are the Mapocho and Poangue. The town is near the Mapocho, and has a church and several monasteries; but is thinly peopled. The Jesuits had a college here.

MELISSA, in mythology, a daughter of Melissus, king of Crete, who, with her sister Amalthæa, fed Jupiter with the milk of goats. She first found out the means of collecting honey; whence it has been fabled that she was changed into a bee, as her name, Μελισσα, is the Greek for that insect.

Melissa, Baum, a genus of the gymnospermia order, and didynamia class of plants: cal. arid, a little plane above, with the upper lip having its dents nearly of equal height: cor. upper lip, arched and bifid; the under one, with the middle lobe, cordated: the most remarkable species are,

1. M. calamintha, or common calamint of the shops, with fibrous perennial roots; upright, square, branchy, hairy stalks, rising a foot high; roundish, indented, opposite leaves; and verticillate clusters of small bluish flowers, on forked foot-stalks, as long as the flowers.

2. M. grandiflora, or Hetrurian calamint, with fibrous perennial roots and annual stalks, rising about a foot high, garnished with oblong, oval, indented, hairy, opposite leaves; and from the upper axillæ verticillate clusters of large purple flowers on forked foot-stalks.

3. M. officinalis, or common baum, with fibrous perennial roots; many upright, square, branchy, annual stalks, rising two or three feet high; garnished with oblong, indented, opposite leaves, by pairs, two or three inches long, and half as broad; and from the upper axillæ verticillate clusters of small white flowers upon single foot-stalks. There is also a variety with variegated leaves. All these species are easily propagated by off-sets. This last, when in perfection, has a pleasant smell, somewhat of the lemon kind; and a weak, roughish, aromatic taste. The young shoots have the strongest flavor; the flowers, and the herb itself, when old or produced in very rich moist soils or rainy seasons, are much weaker both in smell and taste. Baum is appropriated, by the writers on the materia medica, to the head, stomach, and uterus; and, in all disorders of these parts, is said to be very serviceable.

MELISSUS of Samos, a Greek philosopher, was the son of Ragines and the disciple of Parmenides; and lived about 440 B.C. He asserted that the universe is infinite, immoveable, and without a vacuum. Themistocles was among his pupils.

MELITA, or Melite, in ancient geography, an island referred to Africa by Scylax and Ptolemy; but nearer Sicily, and allotted to it by the Romans; commended for its commodious harbours, for a city well built, and for weavers of fine linen. The Phœnicians were the first colonists. It is now called Malta.

MELITENSIS Terra, the earth of Malta, an earth of which there are two very different kinds; the one of the genus of boles, the other of marls. The latter is that known by medicinal authors under this name; the former is the Malta earth now in use; but both, being brought from the same place, are confusedly called by the same name. The Maltese marl, which is the terra Melitensis of medicinal authors, is a loose, crumbly, and very light earth, of an unequal and irregular texture, and when exposed to the weather, soon falls into fine soft powder; but, when preserved and dried, it becomes a loose, light mass, of a dirty white color, with a grayish cast: it is rough to the touch, adheres firmly to the tongue, is very easily crumbled to powder between the fingers, and stains the hands. Thrown into the water, it smells, and afterwards moulders away into a fine powder. It ferments very violently with acid menstruums. Both kinds are found in great abundance in the island, and the latter has been much esteemed as a remedy against the bites of venomous animals. The other has supplied its place in the German shops; and is used there as a cordial, sudorific, and astringent.

MELITO, bishop of Sardis in Lydia, in the second century, was remarkable for the apology he presented to the emperor Aurelius, in favor of the Christians; on which Eusebius and other ancient ecclesiastical writers bestow great praises; but that and all Melito's other works are lost.

MELITTIS, in botany, baum-leaved archangel, or bastard baum, a genus of the gymnospermia order, and didynamia class of plants; natural order forty-second, verticillatæ.

MELITUS, a Greek orator and poet, the accuser of Socrates. The Athenians, after the death of Socrates, discovering the iniquity of the sentence they had passed against that great philosopher, put Melitus to death, 400 B.C.

MELL, *v. n.* Fr. *meler*. To mix; meddle. Obsolete.

> In no wise dare I more *mell*
> Of thing wherein such peril is
> As like is now, to fall of this.
> *Chaucer's Dreame.*

> It fathers fits not with such things to *mell*.
> *Spenser.*

> Here is a great deal of good matter
> Lost for lack of telling:
> Now I see thou dost but clatter,
> Harm may come of *melling*. *Id. Pastorals.*

MELLAN (Claude), an engraver of considerable note, born at Abbeville in Picardy in 1601. His father was the receiver of the customs in that town, and took great care of his education. His genius for drawing appearing very early, he was sent to Paris, and placed under the direction of Simon Vouet, to perfect him in that art, and his studies promised success; but he was diverted from his application to them by the desire he had of learning the management of the graver, which he acquired with much facility. From Paris, at the age of sixteen, he went to Rome, where he engraved a considerable number of plates, many of which are held in great estimation; particularly those for the Justinian Gallery, the portrait of the marquis Justinian, and that of pope Urban VIII. Returning to France, he married and settled at Paris, in 1654. Louis XIV., being made acquainted with his merit, assigned him apartments in the Louvre, in the double quality of a painter and an engraver. He acquired a competent fortune, and was greatly esteemed. He died in 1688, aged eighty-seven.

MELLIF'EROUS, *adj.* } Lat. *mellifico*, or
MELLIFICA'TION, *n. s.* } *mel* (Gr. μελι) and
MELLIF'LUENCE, } *fluo*. Flowing with
MELLIF'LUENT, *adj.* } honey. Production
MELLIF'LUOUS. } of honey; flowing
with honey or sweetness: this is the sense of all the adjectives. Mellification is the art of making, or the production of honey. Mellifluence, a honied or sweet flow.

MELLITE, or **HONEY-STONE**, in mineralogy, takes its name from its yellow color, like that of honey. Its primitive figure is an octahedron. The crystals are small; their surface is commonly smooth and shining. Internally, it is splendent. It is transparent, passing into the opaque, and possesses double refraction. It is softer than amber, and brittle. Specific gravity 1.5. to 1.7. It becomes electric by friction. It occurs on bituminous wood and earthy coal, at a single locality in Thuringia. It consists of 46 mellitic acid, 16 alumine, and 38 water.

MELLITIC ACID; discovered by Klaproth in the mellite, or honey-stone. It is procured by reducing the mellite to powder, and boiling it with about 72 times its weight of water; the alumine is precipitated in the form of flakes, and the acid combines with the water. By filtration and evaporation, crystals are deposited, in the form of fine needles, or in small, short prisms. It is composed of carbon, hydrogen, and oxygen. In combination with the earthy alkalies and metallic oxides, it forms compounds called *mellates*.

MEL'LOW, *adj.*, *v.a.* & *v.n.* } French *mol*,
MEL'LOWNESS. } *moelleux*; Ital.
and Span. *molle*; Port. *mole*; all perhaps of Lat. *mollis*, soft. Ripe to softness; mature; soft in sound; unctuous; subdued or melted down by drink; intoxicated. To mellow is to ripen; mature; bring to or towards perfection: hence to ameliorate; make better in any way; be matured; ripen. Mellowness follows these senses.

An apple in my hand works different effects upon my senses: my eye tells me it is green; my nose, that it hath a *mellow* scent; and my taste, that it is sweet. *Digby.*

> The spring, like youth, fresh blossoms doth produce,
> But Autumn makes them ripe, and fit for use:
> So age a mature *mellowness* doth set
> On the green promises of youthful heat. *Denham.*

> Greedy of physicians frequent fees,
> From female *mellow* praise he takes degrees.
> *Roscommon.*

> A little longer,
> And Nature drops him down without your sin,
> Like *mellow* fruit, without a winter storm.
> *Dryden.*

> Of seven smooth joints a *mellow* pipe I have,
> Which with his dying breath Damætas gave. *Id.*

They plow in the wheat stubble in December; and, if the weather prove frosty to *mellow* it, they do not plow it again till April. *Mortimer's Husbandry.*

> On foreign mountains may the sun refine
> The grape's soft juice, and *mellow* it to wine.
> *Addison.*

> In all thy humours, whether grave or *mellow*,
> Thou'rt such a testy, touchy, pleasant fellow:
> Hast so much wit, and mirth, and spleen about thee,
> There is no living with thee, nor without thee. *Id.*

> When thou wast corn't, an' I was *mellow*,
> We took the road aye like a swallow:
> At Brooses thou had ne'er a fellow. *Burns.*

> As time improves the grape's authentic juice,
> *Mellows* and makes the speech more fit for use,
> And claims a reverence in its shortening day,
> That 'tis an honour and a joy to pay. *Cowper.*

> The rose was yet upon her cheek,
> But *mellowed* with a tenderer streak:
> Where was the play of her soft lips fled?
> Gone was the smile that enlivened the red.
> *Byron.*

MELMOTH (William), esq., a learned bencher of Lincoln's Inn, was born in 1666. In conjunction with Mr. Peere Williams, he published Vernon's Reports, under an order of the court of chancery. But the performance for which he most deserves to be held in remembrance is, The Great Importance of a Religious Life; of which, after many large editions had been circulated, 42,000 copies were sold within eighteen years, before the real author was known. Few men, it has been truly said, have ever passed a more useful, not one a more blameless life. He died on the 6th of April, 1743.

MELMOTH (William), esq., son of the preceding, the celebrated translator of Pliny and of Cicero's Letters; and author of those which pass under the name of Sir Thomas Fitzosborne.

MELOCHIA, Jews' mallow, in botany, a genus of the pentandria order, and monodelphia class of plants: CAPS. quinquelocular and monospermous. There are several species; but the only remarkable one is,

M. olitorius, the common Jew's mallow, a native of the warm parts of Asia and America. It is an annual plant, which rises about two feet high, dividing into several branches, garnished with leaves of different sizes and forms: some spear-shaped, others oval, and some almost heart-shaped: they are of a deep green, and slightly indented on their edges, having near their base two bristly reflexed segments. They have very long slender foot-stalks, especially those which grow on the lower part of the branches. The flowers sit close on the opposite side of the branches to the leaves, coming out singly; they are composed of five small yellow petals, and a great number of stamina surrounding the oblong germen, which is situated in the centre of the flower, and afterwards turns to a rough swelling capsule two inches long, ending in a point, and having four cells filled with angular greenish seeds. This species is cultivated about the city of Aleppo in Syria, and in the East Indies, as a pot-herb; the Jews boiling the leaves, and eating them with their meat. It is supposed by Rauwolf to be the olus Judaicum of Avicenna, and the corchorum of Pliny.

MELOCO'TON, *n. s.* Spanish *melocotone;* Lat. *malum cotoneum.* A quince. Obsolete.

In apricots, peaches, or *melocotones* upon a wall, the greatest fruits are towards the bottom. *Bacon.*

MEL'ODY, *n. s.* } Fr. *melodie:* Latin
MELO'DIOUS, *adj.* } *melodia;* Gr. μελῳδια.
MELO'DIOUSLY, *adv.* } Music; harmony or
MELO'DIOUSNESS, *n. s.* } sweetness of sound:
the other derivatives correspond.

Singing and making *melody* in your hearts to the Lord. *Ephesians.*

The prophet David having singular knowledge not in poetry alone but in musick also, judging them both to be things most necessary for the house of God, left behind him a number of divinely indited poems, and was farther the author of adding unto poetry *melody* in public prayer, *melody* both vocal and instrumental, for the raising up of men's hearts, and the sweetening of their affections towards God. *Hooker.*

Why rather, sleep, liest thou in smoky cribs,
And husht with buzzing night flies to thy slumber;
Than in the perfumed chambers of the great,
And lulled with sounds of sweetest *melody?*
Shakspeare.

Fountains! and ye that warble, as ye flow,
Melodious murmurs; warbling tune his praise.
Milton.

And oft with holy hymns he charmed their ears;
A musick more *melodious* than the spheres.
Dryden.

Lend me your songs, ye nightingales: Oh pour
The mazy-running soul of *melody*
Into my varied verse! *Thomson's Spring.*

The lover, in *melodious* verses,
His singular distress rehearses,
Still closing with a rueful cry,
Was ever such a wretch as I! *Cowper.*

MELOE, in zoology, a genus of insects of the order of coleoptera. The antennæ are jointed, the last joint being oval; the breast is roundish; the elytra are soft and flexible; and the head is inflected and gibbous. This genus is divided into two families; one without wings, and having the elytra shorter than the abdomen; the other winged, with elytra shorter than the body, and wholly covering the wings. See ENTOMOLOGY.

M. proscarabæus, the color is black, but without brightness, though intermixed with a small degree of purple, especially towards the under part of the body. Its head, which is large is dotted; as is the thorax, which is narrower, round, and has no margin. The elytra are as soft as leather, shagreened, and cover but one part of the abdomen. They seem cut off obliquely from the inner to the outer part, being shorter towards the suture, longer on the sides. There are no wings under the elytra. The abdomen is large, especially that of the female, in which it far exceeds the elytra. This insect makes its abode on the side of wet roads and in woods. Its food is insects, violet leaves, and delicate herbs. A fat unctuous matter of an agreeable smell oozes from its body. The males are less than the females. Oil, in which insects of this species have been infused, is said to be an excellent remedy for wounds and the scorpion's sting. It enters also into the composition of salve for plague sores. The insects bruised and mixed with oil or honey, Linnæus says, are recommended as a remedy in the rabies canina. See ENTOMOLOGY.

ME'LON, *n. s.* Fr. *melon;* Lat. *melo.* A species of cucumis. See below.

We remember the fish which we did eat in Egypt freely; the cucumbers and the *melons.* *Num.* xi. 5.

The southern wits are like cucumbers, which are commonly all good in their kind; but at the best are an insipid fruit; while northern geniuses are like *melons,* of which not one in fifty is good; but when it is, it is an exquisite relish. *Berkeley.*

The flower of the *melon* consists of one leaf, which is of the expanded bell shape, cut into several segments, and exactly like those of the cucumber, &c. *Miller.*

MELON, in botany. See CUCUMIS. The female flowers have no stamina or summits, but have a very large oval germen, situated below the flower, which turns to an oval fruit with several cells, filled with oval, acute pointed, compressed seeds, enclosed in a soft pulp. Great varieties of this fruit are cultivated in different parts of the world, many of them of no value, size being regarded too much in the markets. The cantaleupe melon, so called from a place near Rome, where this fruit has been long cultivated, and whither it was brought from Armenia, is in the greatest esteem among the curious. There are also the romana, the succadoe, the Zatte, the small Portugal or dormer, and the black Galloway melons, most of which are cultivated for an early crop. The proper management and culture of melons are as follow:—The seed from which they are to be propagated should be from three to six years old, sown at two different periods, to obtain a succession of crops. For those of the first season the seed may be set about the middle of February, on a cucumber bed, two inches from each other, and covered with a little earth. When a fortnight old they should be transplanted, and, in three weeks after, finally removed to the bed on which they are intended to remain, which ought to be in a warm situation, so as to be defended

from cold and violent winds. The second crop should be sown about the middle of March, and treated in a similar manner. But the hot-bed, formed with the view of rearing these tender exotics, ought to evaporate two or three days before it be ready for the reception of the plants; which should be carefully removed without injuring their fibres. After they are placed on the tops of the hills, raised of garden-mould above the dung, water them once or twice till they have taken root, when their management will vary but little from that of cucumbers, excepting that melons require more air and a small quantity of water. As soon as the plant spreads into branches it must be properly clipped: so that only two of the principal shoots may remain; and, to produce perfect and ripe fruit, one only should be left on each stem, and all superfluous young melons removed as soon as they appear. Besides, the diseased leaves and branches, together with the forked extremities, ought to be continually cut off; and when the fruit is set, or formed, it will be necessary to place thin boards or stones under each, and to turn it gently twice a-week, that the whole may be equally benefited by the sun and air. When fully grown, it must be plucked at a proper time, as it will otherwise lose a considerable part of its flavor. Thus, if melons be intended for the table they should be cut early in the morning, immersed in ice or cold spring water, and kept in the coolest place till they are used. The most certain criterion, to ascertain the maturity of this fruit, is its cracking near the foot-stalk, and beginning to smell.

MELOS, in ancient geography, an island between Crete and Peloponnesus, about twenty-four miles from Scyllæum. It is about sixty miles in circumference, and of an oblong figure. It enjoyed independence for above 700 years befor the Peloponnesian war. It was originally peopled by a Lacedemonian colony, about A.A.C. 1116. For this reason the inhabitants refused to join the rest of the islands and the Athenians against the Peloponnesians. This refusal was severely punished. The Athenians took Melos, and put to the sword all who were able to bear arms. The women and children were made slaves, and the island desolated. An Athenian colony repeopled it, till Lysander reconquered it, and restored the inhabitants to their possessions. It is now called Milo, as well as its capital. See MILO.

MELOTHRIA, in botany, small creeping cucumber, a genus of the monogynia order and triandria class of plants; natural order thirty-fourth, cucurbitaceæ: CAL. quinquefid: COR. campanulated and monopetalous; berry trilocular and monospermous. There is only one species, viz.

M. pendula, a native of Carolina, Virginia, and many of the American islands. The plants strike out roots at every joint, which fasten their stalks in the ground, by which means they extend far every way. The flowers are very small, shaped like those of the melon, of a pale sulphur color. The fruit in the West Indies grows to the size of a pea, is of an oval figure, and changes to black when ripe: these are by the inhabitants sometimes pickled when green. In Britain the fruit are much smaller, and are so hidden by the leaves that it is difficult to find them. The plants in this country require artificial heat.

MELPOMENE, in mythology, one of the nine muses, daughter of Jupiter and Mnemosyne. She presided over tragedy. Horace has addressed one of the finest of his odes to her, as to the patroness of lyric poetry. She was generally represented as a young woman with a serious countenance. Her garments were splendid; she wore a buskin, and held a dagger in one hand, and in the other a sceptre and crown.

MELROSE, a town of Roxburgh, on the confines of Tweeddale; seated on the south side of the Tweed; with an ancient abbey, now in ruins, founded by king David I. in 1136. He peopled it with Cistertians from Rivale abbey in Yorkshire, and dedicated it to the Virgin Mary. At the Reformation James Douglas was made commendator, who took down much of the building, to furnish materials for a large house for himself, which still remains. Nothing is left of the abbey excepting a part of the cloister walls elegantly carved; but the ruins of the church are most strikingly beautiful. Part is at present used for divine service, the rest uncovered; but every part does great honor to the architect. Alexander II. was buried beneath the great altar. This ancient monastery is mentioned by Bede, as having been founded in the end of the sixth century; and Sir Walter Scott's description of it, in the Lay of the Last Minstrel, has attracted numbers of travellers to the spot. Sir Walter's seat of Abbotsford is in the immediate vicinity. Melrose has fairs in March, June, August, and November.

MELT, *v. a.* & *v. n.*
MELT'ER, *n. s.*
MELT'ING, *adj.*
MELT'INGLY, *adv.*
} Sax. meltan; Goth. and Swed. *melta*; Belg. *smelten*; Gr. *μελδω*. To dissolve; make or reduce into liquid: hence to break into small particles; waste; and metaphorically to soften to regard or tenderness; waste away: as a neuter verb, to become liquid; be dissolved or lose substance; be softened into compassion, tenderness, or gentleness. A melter is particularly applied to one that smelts metals. Melting and meltingly follow the senses of the verb.

My soul *melteth* for heaviness: strengthen thou me. *Psalm.*

When the *melting* fire burneth, the fire causeth the waters to boil. *Isa.* lxiv. 2.

Miso and Mopsa, like a couple of foreswat *melters*, were getting the pure silver of their bodies out of the ore of their garments. *Sidney.*

Zelmane lay upon a bank, that her tears falling into the water, one might have thought she began *meltingly* to be metamorphosed to the running river. *Id.*

How they would *melt* me out of my fat drop by drop, and liquor fishermen's boots with me. *Shakspeare.*

Thou would'st have plunged thyself
In general riot, *melted* down thy youth
In different beds of lust. *Id. Timon of Athens.*

Dighton and Forrest,
Albeit they were flesht villains, bloody dogs,

Melting with tenderness and mild compassion,
Wept like two children in their death's sad story.
Shakspeare.

Whither are they vanished?
—Into the air: and what seemed corporal
Melted as breath into the wind. *Id. Macbeth.*

The rose is fragrant, but it fades in time;
The violet sweet, but quickly past the prime;
While lillies hang their heads and soon decay,
And whiter snow in minutes *melts* away.
Dryden.

The mighty master smiled to see
That love was in the next degree:
'Twas but a kindred sound to move,
For pity *melts* the mind to love. *Id.*

Melting into tears, the pious man
Deplored so sad a sight. *Id.*

This price, which is given above the value of the silver in our coin, is given only to preserve our coin from being *melted* down. *Locke.*

To take in pieces this frame of nature, and *melt* it down into its first principles; and then to observe how the divine wisdom wrought all these things into that beautiful composition; is a kind of joy which pierceth the mind. *Burnet.*

Alas! the story *melts* away my soul, *Addison.*

This the author attributes to the remissness of the former *melters*, in not exhausting the ore.
Derham's Physico-Theology.

The rock's high summit in the temple's shade,
Nor heat could *melt*, nor beating storm invade.
Pope.

If your butter wnen *melted* tastes of brass, it is your master's fault, who will not allow you a silver saucepan. *Swift.*

What with afflicted beauty can compare,
And drops of love distilling from the fair?
It *melts* us down; our pains delight bestow,
And we with fondness languish o'er our woe.
Young.

MELVILLE ISLAND in the North Polar Sea; one of the North Georgian group, between 74° and 76° 50' N., lat., and 105° 40', and 113° 40' W., long. It is surrounded with enormous masses of ice, and the only vegetation is moss. Captain Parry discovered it in 1819, and passed the winter of 1819—20 there.

MELTING CONE, in assaying, a hollow cone of brass or cast iron, into which melted metalline substances are thrown, in order to free them from their scoriæ. When a small quantity of matter is melted it will be sufficient to rub the inside of the cone with grease; but when the quantity is very large, especially if it contain any thing sulphureous, this caution of tallowing the moulds is not sufficient. In this case the assayer has recourse to a lute reduced to thin pap with water, which effectually prevents any injury to the cone.

MELVIL (Sir James), descended from an honorable Scots family, being the third son of the laird of Kaeth, was born in 1530. He went to France very young, as page to queen Mary, then married to the dauphin; and on the death of her husband followed her to Scotland, where he was made gentleman of her chamber, and admitted a privy counsellor. She employed him in her most important concerns, till her confinement in Lochleven, all which he discharged with the utmost fidelity; and, had she taken his advice, she might have avoided many of her misfortunes. When she was prisoner in England, she recommended him strongly to her son James with whom he continued in favor and employment until the death of queen Elizabeth: James would then have taken him to England; but Melvil, now grown old, was desirous of retiring from business, and in his retirement he drew up the memoirs of his past life for the use of his son. These Memoirs were accidentally found in Edinburgh castle in 1660, and published in folio in 1683.

MELVILLE BAY, a harbour on the north coast of New Holland, in the west entrance of the gulf of Carpentaria, said by captain Flinders to be the best harbour in the gulf. The entrance from the N. N. W. is four miles wide; and the bay every where affords good anchorage. On the south and eastern sides the country was found covered with pasturage and trees. Among the latter kangaroos appeared to be numerous. Long. of Point Dundas, at the entrance of the bay, 136° 41' 40" E., lat. 12° 13' 0" S.

MELVILLE, CAPE, the north-west point of Hispaniola. Long. 60° 30' W., lat. 15° 44' N.

MELVILLE ISLES are formed of an island, with several smaller rocky islets adjoining, on the north shore of New Holland, at the entrance into the gulf of Carpentaria. The island is low, about five miles long, and between one and two in breadth. It is barren, and the shores in general are sandy. The south end lies in long. 136° 52' E., lat. 12° 8' 30" S.

MELUN, an ancient and handsome town, the principal place of the department of the Seine et Marne, in France, having a minor court of justice, subject to the royal court of Paris, a communal college, a free drawing school, an agricultural society, a public library of 8000 volumes, an assembly room, and several pleasant public walks. It is a post town, situated at the foot of a hill, containing about 7000 inhabitants: the river Seine running through it and dividing it into several parts. It has tolerably open streets: in the eastern part of the Isle of France, near it, are the ruins of a palace, once inhabited by the French monarchs, and where Blanche, the mother of St. Louis, for some time held her court. Melun was besieged and taken several times by the English and by the duke of Burgundy; the former reduced it by famine in 1419, but fourteen years after the inhabitants drove them out and admitted the troops of Charles VII.

Its manufactures consist of flint glass, cloth, drugget, serge, printed linens, calicoes, &c. &c. There are also some cotton spinning factories, tan-yards and bark-mills, lime-kilns, &c. The inhabitants carry on a trade in corn, flour, wines, cheese, wool, and cattle. There is a considerable corn-market here for the supply of Paris, and a central jail for five departments. Near this place was born James Amyot, the translator of Plutarch. It is situated twelve miles north of Fontainbleau, thirty-nine south of Meux, and thirty-four S. S. E. of Paris.

MEM'BER, *n. s.* Fr. *membre;* Ital. *membro;* Lat. *membrum:* [Ex. Gr. μερος, quòd membra sint partes corporis; qu. per redupl. μεμερος?—Ainsworth.] Any part of a thing or person: an obvious or conspicuous part: hence a limb; in-

tegral or principal part of a discourse or poem; an architectural division of a column, capital, &c.; one of a community.

It is profitable for thee that one of thy *members* should perish, and not that thy whole body should be cast into hell. *Matthew.*

My going to demand justice upon the five *members*, my enemies loaded with obloquies. *King Charles.*

If shape it might be called, that shape had none,
Distinguishable in *member*, joint, or limb. *Milton.*

Mean as I am, yet have the Muses made
Me free, a *member* of the tuneful trade. *Dryden.*

In poetry, as in architecture, not only the whole but the principal *members*, should be great. *Addison.*

Sienna is adorned with many towers of brick, which, in the time of the commonwealth, were erected to such of the *members* as had done service to their country. *Addison.*

The peace and happiness of a society depend on the justice and fidelity, the temperance and charity, of its *members*. *Rogers.*

Where the respondent limits or distinguishes any proposition, the opponent must prove his own proposition according to that *member* of the distinction in which the respondent denied it. *Watts.*

MEM'BRANE, *n. s.* | MEMBRANA'CEOUS, *adj.* | MEMBRA'NEOUS, | MEM'BRANOUS. } French *membrane*, *membraneux*; Latin *membrana*, (that which binds together the members.—Priscian.) A fibrous integument of the body. See the extract from Quincy. The adjectives mean consisting of, or pertaining to, membranes.

They obstacle find none
Of *membrane*, joint, or limb, exclusive bars:
Easier than air with air, if spirits embrace,
Total they mix. *Milton.*

The chorion, a thick *membrane* obscuring the formation, the dam doth after tear asunder.
Browne's Vulgar Errours.

Great conceits are raised of the involution or *membranous* covering called the silly-how. *Browne.*

The inner *membrane* that involved the several liquors of the egg remained unbroken. *Boyle.*

Lute-strings, which are made of the *membraneous* parts of the guts strongly wreathed, swell so much as to break in wet weather. *Id.*

Such birds as are carnivorous have no gizzard, or musculous, but a *membranous* stomach; that kind of food, being torn into small flakes by the beak, may be easily concocted by a *membranous* stomach.
Ray on the Creation.

A *membrane* is a web of several sorts of fibres, interwoven together for the covering and wrapping up some parts: the fibres of the *membranes* give them an elasticity, whereby they can contract, and closely grasp the parts they contain, and their nervous fibres give them an exquisite sense, which is the cause of their contraction; they can, therefore, scarcely suffer the sharpness of medicines, and are difficultly united when wounded. *Quincy.*

Anodyne substances, which take off contractions of the *membranous* parts, are diuretick. *Arbuthnot.*

Birds of prey have *membranaceous*, not muscular stomachs. *Id. on Aliment.*

MEMEL, a fortified town of Prussia, on the Dange, adjacent to the Curische Haff, which here joins the Baltic by a narrow strait, and receives the great river Memel or Niemen, which is navigable through a great part of Lithuania. It has three suburbs, one of which lies beyond the Dange. The situation commands a good regular trade in timber, particular deals, brought down in floats; hemp, flax, corn; hides and skins; tallow, bristles, wax, feathers, and Lithuanian yarn. The imports are chiefly coffee, sugar, pepper, dye-woods, tobacco, rum, and cotton goods. Lying only about thirteen miles from the Russian frontier, this town also carries on a good deal of smuggling with that country. The average number of vessels, great and small, that visit the harbour, is from 600 to 700, of which two-thirds are British. The entrance of the harbour is obstructed by shoals and quicksands, so that it will not admit vessels drawing above eighteen feet of water. The exchange transactions are generally conducted at Konigsberg. The manufactures are trifling, with the exception of the saw-mills for cutting deals, logs, and boards. Population 6000. Seventy miles N. N. E. of Konigsberg, and 130 north-east of Dantzic.

MEMEN'TO, *n. s.* | MEMOIR', | MEM'ORABLE, *adj.* & *n. s.* | MEM'ORABLY, *adv.* | MEM'ORATIVE, *adj.* | MEMORAN'DUM, *n. s.* | MEMO'RIAL, | MEMO'RIALIST, | MEM'ORIZE, *v. a.* | MEM'ORY, *n. s.* } Lat. *memento*, *memorabilis*, *memorandum*, *memorialis*, *memoria* · Fr. *memorie*, *memorable*, *memorial*. Notice, remark, or hint, to assist recollection. A memoir is a collection of such notices; used particularly with regard to personal or family history. Memorably, worthy of being recollected. Memorandum, a note to assist memory. Memorial, as an adjective, assisting memory; retained in memory; (memorative is used by bishop Hall in the former sense): as a substantive, a monument, or other formal record of a person's history, or of particular transactions. A memorialist is the writer, or he who presents a memorial. To memorize is to record; cause to be remembered. Memory, the power or faculty of recollection; fame; time of knowledge.

A *memorial* unto Israel that no stranger offer incense before the Lord. *Num.* xvi. 43.

Nothing I so much delight to recount, as the *memorable* friendship that grew betwixt the two princes.
Sidney.

Churches have names, some as *memorials* of peace, some of wisdom, some in *memory* of the Trinity itself, some of Christ under sundry titles; of the blessed Virgin not a few; many of one apostle, saint, or martyr; many of all. *Hooker.*

They neglect to *memorize* their conquest of the Indians, especially in those times in which the same was supposed. *Spenser.*

When Duncan is asleep, his two chamberlains
Will I with wine and wassel so convince,
That *memory*, the warder of the brain,
Shall be a fume. *Shakspeare. Macbeth.*

That ever living man of *memory*,
Henry the Fifth! *Id. Henry VI.*

Be better suited;
These weeds are *memories* of those worser hours:
I pr'ythee put them off. *Id. King Lear.*

They meant
To *memorize* another Golgotha.
Shakspeare.

Thy master now lies thinking in his bed
Of thee and me, and sighs, and takes my glove,
And gives *memorial* dainty kisses to it. *Id*

Our master, for his learning and piety, is not only a precedent to his own subjects, but to foreign princes; yet he is but a man, and seasonable *mementos* may be useful. *Bacon.*

From this desire, that main desire proceeds,
Which all men have surviving fame to gain,
By tombs, by books, by *memorable* deeds,
For she that this desires doth still remain. *Davies.*

Memorials written with kind Edward's hand shall be the ground of this history. *Hayward.*

Let their names that were bravely lost be rather *memorized* in the full table of time; for my part, I love no ambitious pains in an eloquent description of miseries. *Wotton.*

Do but cast your eyes back upon the fresh *memory* of those late flourishing times of this goodly kingdom, when pure religion was not more cheerfully professed than inviolably maintained. *Bp. Hall.*

The same thoughts do commonly meet us in the same places, as if we had left them there till our return; for that the mind doth secretly frame to itself *memorative* heads, whereby it recals easily the same conceits. *Id.*

Our *memories* are so frail that they need instruments of recollection, and laborious artifices to help them. *Jer. Taylor.*

In other parts like deeds deserved
Memorial, where the might of Gabriel fought.
Milton.

Thy request think now fulfilled, that asked
How first this world, and face of things, began,
And what, before thy *memory*, was done. *Id.*

All the laws of this kingdom have some monuments or *memorials* thereof in writing, yet all of them have not their original in writing; for some of those laws have obtained their force by immemorial usage. *Hale.*

Dares Ulysses for the prize contend,
In sight of what he durst not once defend;
But basely fled that *memorable* day,
When I from Hector's hands redeemed the flaming prey? *Dryden.*

Is not the frequent spectacle of other people's deaths a *memento* sufficient to make you think of your own? *L'Estrange.*

Memory is the power to revive again in our minds those ideas which after imprinting have disappeared, or have been laid aside out of sight. *Locke.*

I resolved to new-pave every street, and entered a *memorandum* in my pocket-book accordingly.
Guardian.

I must not omit a *memorial* setting forth, that the *memorialist* had, with great dispatch, carried a letter from a certain lord to a certain lord. *Spectator.*

As the *memory* relieves the mind in her vacant moments, and fills up the chasm of thought with ideas of what is past, we have other faculties that agitate and employ her upon what is to come. These are the passions of hope and fear. *Id.*

Medals are so many monuments consigned over to eternity, that may last when all other *memorials* of the same age are worn out or lost. *Addison.*

There is not so variable a thing in nature as a lady's head-dress. Within my own *memory* I have known it rise and fall within thirty degrees. *Id.*

Reflect upon a clear, unblotted, acquitting conscience, and feed upon the ineffable comforts of the *memorial* of a conquered temptation. *South.*

Be our great master's future charge
To write his own *memoirs*, and leave his heirs
High schemes of government and plans of wars.
Prior.

The tomb with manly arms and trophies raise;
There high in air *memorial* of my name
Fix the smooth oar, and bid me live to fame. *Pope.*

There is not in any author a computation of the revenues of the Roman empire, and hardly any *memoirs* from whence it might be collected.
Arbuthnot on Coins.

Nature's fair table-book, our tender souls,
We scrawl all o'er with old and empty rules,
Stale *memorandums* of the schools. *Swift.*

May I, at the conclusion of a work, which is a kind of monument of Pope's partiality to me, place the following lines as an inscription *memorial* of it.
Broome.

The case is with the *memorial* possessions of the greatest part of mankind: a few useful things mixed with many trifles fill up their *memoirs*. *Watts.*

He resolved to disappoint the effects of their negociations, by entering into a closer union with his nephew. In order to accomplish this, he transmitted to James an elaborate *memorial*, representing the numerous encroachments of the see of Rome upon the rights of sovereigns.
Robertson. History of Scotland.

Excesses of all kinds do a great injury to the *memory*. *Mason.*

They spake of him they loved, of him whose life,
Though blameless, had incurred perpetual strife;
Whose deeds had left, in spite of hostile arts,
A deep *memorial* graven on their hearts. *Cowper.*

Theresa's form—
Methinks it glides before me now,
Between me and yon chesnut's bough,
The *memory* is so quick and warm;
And yet I find no words to tell
The shape of her I loved so well. *Byron.*

MEMMINGEN, a walled town of Bavaria, on the Iller, has a neat town-house, a merchants' hall, arsenal, barracks, a public library, and a high school. Its manufactures are on a small scale, and consist of the weaving and printing cottons and linen, tanneries, tobacco, woollen, iron and copper works. In the environs hops are cultivated. Population 6500, chiefly Lutherans. Twenty-eight miles south by east of Ulm.

MEMNON, in fabulous history, a king of Ethiopia, son of Tithonus and Aurora. He came with a body of 10,000 men to assist his uncle Priam during the Trojan war. He behaved with great courage, and killed Antilochus, Nestor's son. The aged father challenged the Ethiopian monarch; but Memnon refused it on account of the venerable age of Nestor, and accepted that of Achilles. He was killed in the combat, in the sight of the Grecian and Trojan armies. Aurora prayed Jupiter to grant her son such honors as might distinguish him from other mortals. The god consented; and immediately a numerous flight of birds issued from the burning pile on which the body was laid, and dividing themselves into two separate bodies, fought with such fury, that above half of them fell in the fire as victims to appease the manes of Memnon. These birds were called Memnonides: and it has been said, by some of the credulous ancients, that they never failed to return every year to the tomb of Memnon in Troas, and repeat the same bloody engagement in honor of that hero. The Ethiopians or Egyptians, over whom Memnon reigned, erected a celebrated statue to his memory. This statue had the wonderful property of uttering a melodious sound every day at sun-rising, like that which was heard at the breaking of the string of a harp when it was wound up: effected, it is

said by the rays of the sun, when they fell upon it. At the setting of the sun, and in the night, the sound was lugubrious. Such is the testimony of the geographer Strabo, who confesses himself ignorant, however, whether the sound proceeded from the basis of the statue, or the people that were then around it. This celebrated statue was dismantled by order of Cambyses when he conquered Egypt: but its ruins still astonish modern travellers by their grandeur and beauty.

MEMNON OF RHODES, one of the generals of Darius king of Persia. He advised that prince to lay waste the country, in order to deprive Alexander the Great's army of support, and afterwards to attack Macedon; but this counsel was disapproved by Darius's other generals. Memnon behaved, at the passage of the Granicus, like an experienced general. He afterwards defended the city of Miletum with great courage; seized the islands of Chio and Lesbos: spread terror throughout all Greece; but was stopped in his progress by the hand of death. Barsina, Memnon's widow, was taken prisoner with Darius's wife, and Alexander had a son by her named Hercules.

MEMORY is that faculty of the mind which presents to us ideas of what is past, accompanied with a persuasion, that the things themselves were formerly real and present. What we distinctly remember to have perceived, we as firmly believe to have happened, as what is now present to our senses. The means by which the mind retains the ideas of past objects, and how these ideas carry with them evidence of their objects having been actually perceived, will be found noticed in our article METAPHYSICS. The ingenious Dr. Beattie, in his Elements of Moral Science, divides memory into two species, active and passive.' 'When we remember,' says he, 'with little or no effort, it is called remembrance simply, or memory, and sometimes passive memory. When we endeavour to remember what does not immediately, and, as it were, of itself, occur, it is called active memory, or recollection.' This is a talent of importance in every situation of life, and many rules have been laid down for its acquisition, direction, improvement, and preservation. Perhaps the most important practical observation on the subject is, that sensual excess of any kind is prejudicial to the brain, and gradually impairs this faculty. Such, indeed, is the precarious state of our mental powers, and particularly of our recollection, that it often happens, even with the most regular and temperate, that, notwithstanding every effort, those ideas, which appear to be the most interesting and desirable to be retained, vanish from the mind irrecoverably. To correct this inherent weakness various methods have been proposed, which constitute what is called the art of memory. Those of our readers who are inclined to avail themselves of such assistance, may consult Dr. Gray's treatise, entitled A New Method of Artificial Memory, or our article MNEUMONICS. But let them remember that it is not extraneous aid, but constant attention and exercise, which form the true art of memory. 'It is the practice of many readers,' says Dr. Beattie, 'to note in the margin of their books the most important passages, the strongest arguments, or the brightest sentiments. Thus they load their minds with superfluous attention, repress the vehemence of curiosity by useless deliberations, and by frequent interruption break the current of narration or the chain of reason, and at last close the volume, and forget the passages and the marks together. Others are firmly persuaded, that nothing is certainly remembered but what is transcribed: and they, therefore, pass weeks and months in transferring large quotations to a common-place-book. Yet, why any part of a book, which can be consulted at pleasure, should be copied, we are not able to discover. The hand has no closer correspondence with the memory than the eye. The act of writing itself distracts the thoughts; and what is read twice is commonly better remembered than what is transcribed. This method, therefore, consumes time, without assisting the memory. But to write an abridgment of a good book may sometimes, be a very profitable exercise. In general, when we would preserve the doctrines, sentiments, or facts, that occur in reading, it will be prudent to lay the book aside and put them in writing in our own words. This practice will give accuracy to our knowledge, accustom us to recollection, improve us in the use of language, and enable us so thoroughly to comprehend the thoughts of other men, as to make them in some measure our own.' 'Our thoughts,' says the author of the Idler, 'have, for the most part, a connexion; so that the thought which is just now in the mind, depends partly upon that which went before, and partly serves to introduce that which follows. Hence we remember best those things of which the parts are methodically disposed and mutually connected. A regular discourse makes a more lasting impression upon the hearer than a parcel of detached sentences, and gives to his rational powers a more salutary exercise: and this may show us the propriety of conducting our studies, and all our affairs, according to a regular plan or method. When this is not done, our thoughts and our business, especially if in any degree complex, soon run into confusion.' It is hardly credible to what a degree both active and passive memory may be improved by long practice. Scaliger reports, of himself, that in his youth he could repeat above 100 verses, having once read them; and Berthicus declares that he wrote his Comment upon Claudian without consulting the text. The extraordinary memory of Magliabechi is well known. See MAGLIABECHI. That of Jedidiah Buxton was of a peculiar kind, so long habituated to numbers, that it could fix on nothing else. See BUXTON. To hope, however, for such degrees of memory as these, would be equally vain as to hope for the strength of Hercules, or the swiftness of Achilles. 'But there are clergymen,' says Dr. Johnson, 'who can get a sermon by heart in two hours, though their memory, when they began to exercise it, was rather weak than strong. And pleaders, with other orators who speak in public and extempore, often discover, in calling instantly to mind all the knowledge necessary on the present occasion, and every thing of importance that may

have been advanced in the course of a long debate, such powers of retention and recollection as, to the man who has never been obliged to exert himself in the same manner, are altogether astonishing. As habits, in order to be strong, must be formed in early life, the memories of children should therefore be constantly exercised; but to oblige them to commit to memory what they do not understand, perverts their faculties, and gives them a dislike to learning.' In a word, those who have most occasion for memory, as orators and public speakers, should not suffer it to lie idle, but constantly employ it in treasuring up and frequently reviving such things as may be of most importance to them; for, by these means it will be more at their command, and they may place greater confidence in it upon any emergency.'

MEMPHIS, an ancient city, and the royal residence of the kings in Upper Egypt; fifteen miles from Delta to the south, according to Pliny: called also Moph and Noph, in Scripture. Though this city is now so completely ruined that authors greatly disagree concerning its situation, yet Strabo says, that in his time it was the most magnificent in Egypt, next to Alexandria. It was the capital of the country: and there was an entire temple of Osiris, where the Apis, or sacred ox, was kept and worshipped; with an apartment for the mother of the ox; a very magnificent temple of Vulcan; a large circus for fighting bulls; and a great colossus in the middle of the city, which was thrown down. There was likewise a temple of Venus, and a serapium in a very sandy place, where the wind heaps up hills of sand very dangerous to travellers; with a number of sphynxes, the heads of some of them only being visible, the others covered up to the middle with sand. He adds, that in the front of the city there were many lakes; and that it contained a number of palaces, at that time in ruins. These buildings, he said, formerly stood upon an eminence; they lay along the side of the hill, stretching down to the lakes and groves, forty stadia from the city. There was likewise a mountain in the neighbourhood, on which were a great number of pyramids, with the sepulchres of the kings, among which two were accounted wonders of the world. From this description, Mr. Bruce concludes, that the celebrated capital of Egypt stood in the place where the villages of Metrahenny are now situated; in opposition to Dr. Shaw's opinion, who thinks it was situated at Geeza, Gisa, or Gyzeh. Savary has also shown, that Gisa was not the situation of the ancient Memphis.. This stood, he says, on the west bank of the Nile, on the spot where the village of Memph now stands, which still preserves the name. Large heaps of rubbish are still to be seen there; but the Arabs have transported to Cairo the columns and remarkable stones, which they have disposed, without taste and without order, in their mosques and public buildings. This city extended as far as Saccara; and was almost wholly encompassed by lakes, part of which are still subsisting. It was necessary to cross them to convey the dead to the sepulchres. The tombs, hewn out of the rock, were closed up with stones of a proportionable size, and covered with sand. These bodies, embalmed with so much care, and preserved with so much respect, are torn from the monuments they repose in, and sold without decency to strangers, by the inhabitants of Saccara. This place is called the plain of mummies. There too we find the well of the birds, into which one descends by a rope, into subterraneous galleries, filled with earthen vases, containing the sacred birds. They are rarely met with entire, because the Arabs break them in hopes of finding idols of gold. They do not conduct travellers into the places where they have found more precious articles. They even close them up carefully, reserving to themselves some secret passages by which they descend. In a journey into Egypt, made by the duke de Chaulnes, he advanced very far into these winding labyrinths, sometimes crawling, and sometimets scrambling on his knes. Informed by Mr. Edward Wortley Montague, who had carefully visited Egypt, he arrived at one of those passages which had an opening shut up from without, by branches of the date tree interwoven, and covered with sand. He remarked there some hieroglyphics in relievo, executed in the highest perfection. But the Arabs resisted every offer he made them to permit him to take drawings or moulds of them. The duke is of opinion that these hieroglyphics, sculptured with so much art that the objects they represent may be discovered at the first sight, might furnish the key of the others, whose contours are simply expressed, and form a sort of alphabet of this unintelligible language. Several pyramids are distinguishable along the mountains which bound Saccara on the west, the greatest part of which appear as lofty as those of Gisa. See PYRAMIDS.

MEMPHREMAGOG, a lake of North America, the greater part of which belongs to Canada, and the rest to the state of Vermont. It is thirty-five miles long, and three broad; in long. 72° 8′ W., lat. 45° N. It communicates with the St. Lawrence, by the river St. Francis, and receives the waters of Black, Barton, and Clyde rivers, which rise in Vermont.

MEN'ACE, *v. a.* & *n. s.* } Fr. *menacer, me-*
MEN'ACER. } *nace;* Lat *minatio,* à *minâ*, a weight. To threaten; a threat: a menacer is one who threatens.

Who ever knew the heavens menace so?
Shakspeare.

From this league
Peeped harms that *menaced* him. *Id.*

How many of us, after a thousand hammerings of the *menaces* of God's law upon our guilty souls, continue yet insensible of our danger! *Bp. Hall.*

Purely to seek God's honour, and in all our actions to regard it as our principal aim—promiseth the best rewards to humility, and *menaceth,* that whoever exalteth himself shall be abased. *Barrow.*

He that would not believe the *menace* of God at first, it may be doubted whether, before an ocular example, he believed the curse at last.
Browne's Vulgar Errours.

What should he do? 'Twas death to go away,
And the god *menaced* if he dared to stay. *Dryden*

Hence, *menacer!* nor tempt me into rage:
This roof protects thy rashness. But begone!
Philips.

MENAGE', *n. s.* Fr. *menage.* A collection of animals.

The horse is a noble creature: which, as it is the strength and pride of France, so wins the hearts and heels of that nation. And whereas there is a double kind of *menage*, as I have heard, one for service, the other for pleasure. *Bp. Hall.*

I saw here the largest *menage* that I ever met with. *Addison.*

Menage (Giles), a celebrated French writer, born at Angers in 1613. He finished his studies in that city, was made advocate, and pleaded, for some time, at Angers, Paris, and Poictiers; but at length became an ecclesiastic, and studied polite literature. He entered into the family of cardinal de Retz, and afterwards went to live in the cloister of Notre Dame, where he held a weekly assembly of learned men. He read a great deal, and was incessantly quoting in his conversation verses in Greek, Latin, Italian, French, &c., on which account he was ridiculed as a pedant. The reputation of his works procured him a place in the academy della Crusca, at Florence. His Requeste des Dictionaires, with the superior interest of his competitor Mr. Bergent, prevented his admission into the French Academy. He died at Paris in 1692, aged seventy-nine. He published many books in prose and verse; the principle are, 1. Miscellaneous Works. 2. The Origin of the French Language. 3. The Origin of the Italian Tongue; Geneva, 1685, folio. 4. Malherbe's Poems, with Notes. 5. Diogenes Laertius, with Observations. 6. Remarks on the French Tongue. 7. Greek, Latin, Italian, and French Poems.

MENAI Strait, and Bridge. Menai Strait is a strait about half a mile across, between the island of Anglesey and the coast of Wales, which has become of considerable importance in modern times as a point of communication between Great Britain and Ireland. The mail from London to Dublin passes this strait regularly: a circumstance which, in the year 1810, induced the house of commons to appoint a select committee 'to enquire into the state of the roads from Holyhead to London; into the regulations for the conveyance of his majesty's mail between London and Dublin; and also into the laws and regulations relating to the conveyance of passengers, goods, and merchandise, between Dublin and Holyhead.' This committee made several reports, in which it recommended various measures for improving the roads in this great line of communication, many of which are now in progress. But, in regard to expedition, it would have been of little avail to have improved the roads, without remedying the delay, the inconvenience, and the danger, experienced in crossing the Menai Strait.

In this year and 1811, therefore, several plans of Bridges were proposed for effecting a regular and unobstructed passage in the place of the Bangor ferry. All the bridges proposed were to be of cast iron, and of sufficient width of span and height of elevation not to obstruct the navigation. Among those approved by the committee of the house of commons, after due investigation, was one of a single arch, of cast iron, of 500 feet span, and 100 feet above the level of high-water in the middle of the arch, projected by Mr. Telford. Although the least expensive of any cast iron bridge of those dimensions, the estimated cost of this bridge was upwards of £127,000. But the construction of such a bridge presented a difficulty in the fixing of proper centering, which could not be accomplished by ordinary means from below, owing to the rocky bottom of the channel, and the depth and rapidity of the tide-way. Mr. Telford was, however, led to devise a new mode of suspending the centering from above, and furnished a design of this kind.

The report of the commissioners being made to parliament, and the necessary funds being granted, in July 1818 directions were given for the commencement of the work, at Ynysy-moch, on the Anglesey shore. It was to consist of one opening of 560 feet between the points of suspension, and 100 feet in height between the high-water line and the lower side of the road-way; and, the road-way being horizontal, this height to be uninterrupted for the whole 560 feet, except where the natural rock, which forms the western abutment, interposes. In addition to these 560 feet, there were to be four arches on the western, and three on the eastern side of the main opening, each fifty feet in span, that is, making in all 850 feet of opening. The road way to consist of two carriage-ways, each twelve feet in breadth, with a foot-path of four feet between them; and the whole to be suspended from four lines of strong iron cables by perpendicular iron rods, placed five feet apart. The suspending power was calculated at 2016 tons, and the weight to be suspended, exclusive of the cables, at 342 tons, leaving a disposable power of 1674 tons. The estimated expense was £70,000.

In will be seen, in our articles Anglesey and Beaumaris, that this noble undertaking has been successfully accomplished; we only reserve some remarks upon its scientific structure to the general article Suspension Bridges.

MENANCABOW, an entire state or empire of the island of Sumatra, situated under the equator. It formerly extended over the whole island; but has been on the decline ever since Sumatra was first visited by European navigators. In more modern times its limits have been included between the river Palembang and that of Siak on the eastern side of the island; and, on the western side, between those of Manjuta (near Indrapur) and Singkel, where it borders on the country of the Battas. The present seat, or more properly seats, of the divided government, lie at the back of the Tiga-blas koto district. The country is chiefly one large plain, surrounded by hills producing gold, and comparatively well cultivated. Its communication with the eastern side of the island is facilitated by means of a large lake, described by some traders as equal to a day's sailing, and by others as about the length of from twenty-five to thirty miles. From this lake a river flows east, and the banks are well peopled by Malay colonies. The arts are here carried to a greater degree of perfection than in any other part of Sumatra: these Malays being the sole fabricators of the

exquisite gold and silver filagree of this part of the world. In this country also they have, from the earliest times, manufactured arms for their own use, and that of the northern inhabitants of the island: they even harden their own steel. The use of cannon in this and other parts of India is mentioned by the oldest Portuguese historians. Their guns are match-locks, springs and flints not having been adopted by them. The barrels are of excellent materials, and of the justest bore. The inhabitants are said always to take aim by lowering, instead of raising, the muzzle of the piece. They have other weapons of the sword and spear kind; and a species of dagger, called a kris, is very generally worn. In the government the sultan or rajah is despotic; but his power is modified by the influence of the aristocracy: and the people are feudal serfs.

MENANDER, an ancient Greek poet, born at Athens in the third year of the 109th Olympiad. His introducing the new comedy, and refining an art which had been so gross and licentious in former times, quickly spread his name over the world. Pliny says that the kings of Egypt and Macedon sent ambassadors and fleets to bring him to their courts, but without success. Of his works, which amounted to above 100 comedies, only nine are left besides the four which Terence borrowed from him. It is chiefly from Terence that most people form their judgment of Menander, the fragments that remain of him not being sufficient to enable them to do it. Quintilian, and other old masters of rhetoric, recommend his works as true patterns of every beauty and grace in public speaking. Cæsar calls Terence only a semi Menander. Menander died in the third year of the 122d Olympiad. His tomb, in the times of Pausanias, was to be seen at Athens, in the way from the Piræus to the city, close by the monument of Euripides.

MENANDER, the founder of a sect called Menandrians. Some say he was a disciple of Simon Magus. He taught that no person could be saved unless he were baptised in his name; and he conferred a peculiar sort of baptism, which would render those who received it immortal in the next world; exhibiting himself to the world, with the phrenzy of a lunatic, as a promised saviour. Irenæus, Justin, and Tertullian say, that he pretended to be one of the æons sent from the pleroma, or ecclesiastical regions, to succour the souls that lay groaning under bodily oppression; and to maintain them against the violence and stratagems of the dæmons that hold the reins of empire in this sublunary world.

MENASSEH BEN ISRAEL, a celebrated rabbi, born in Portugal about 1604. He was the son of Joseph Ben Israel, and followed his father into Holland; where he was educated by rabbi Isaac Uzziel, under whom he made such progress in the Hebrew tongue, that, at eighteen years of age, he succeeded him in the synagogue of Amsterdam. In this post he continued several years, and married Rachel of the Abarbanel family, whom the Jews affirm to be descended from king David. He afterwards went to his brother Ephraim, a rich merchant at Basil; by whose advice he entered into trade. Some time after he came into England, then under the protectorship of Cromwell, who gave him a very favorable reception, and one day entertained him at his table with several other learned divines. However he soon after passed into Zealand; and died at Middleburg about 1659. The Jews at Amsterdam buried him at their own expense. He was a Pharisee, had a lively wit, a solid judgment, and great learning. He wrote many books in Hebrew, Latin, Spanish, and English. The principal of those published in Latin are, 1. His Conciliator; a learned and curious work, in which he reconciles those passages of Scripture which seem to contradict each other. 2. De Resurrectione Mortuorum. 3. De Termino Vitæ. 4. Dissertatio de Fragilitate Humanâ, ex lapsu Adami, deque Divino in bono opere Auxilio. 3. Spes Israel. Dr. Thomas Pococke wrote his life in English.

MENCKE, or MENCKENIUS (Lewis Otto), a learned professer of morality at Leipsic, born at Oldenburg in Westphalia in 1644. He studied in several universities of Germany; and became an able philosopher, civilian, and divine. He was made professor of morality at Leipsic in 1668, and enjoyed that post till his death. He was five times rector of the university of that city, and seven times dean of the faculty of philosophy. He published several works, but his most considerable, and which alone is sufficient to perpetuate his memory, is the Acta Eruditorum, of Leipsic, of which he was the first author, and in which he was engaged till his death. The first volume was published at Leipsic, in 4to., in 1682. He died in 1707, aged sixty-three.

MENCKE, or MENCKENIUS (John Burchard), son to the preceding. After his studies he travelled into England and Holland; and, upon his return, was appointed professor of history at Leipsic, in 1688. He gained great reputation by his lectures, as well as his writings. He wrote many pieces, particularly De Charlataneria Eruditorum Declamationes duæ; an excellent satire on false scholars. 2. Methode pour Etudier l'Histoire, avec un Catalogue des Principaux Historiens, &c. 3. A Continuation of the Acta Eruditorum. He made many additions to Mr. Lenglet's book, especially with regard to the German historians. He died in 1732, aged fifty-eight.

MEND, *v. a.* & *n. s.* } Lat. *emendo*, from *men-*
MEND'ER, *n. s.* } *da*, a fault. To repair a fault or breach; correct; meliorate; help; improve; increase; grow better.

They gave the money to the workmen to repair and *mend* the house. 2 *Chron.* xxxiv. 10.

What trade art thou? A trade that I may use with a safe conscience; a *mender* of bad soles.
Shakspeare. Julius Cæsar.

Whatever is new is unlooked for; and ever it *mends* some, and impairs others: and he that is holpen takes it for a fortune, and he that is hurt for a wrong.
Bacon.

Death comes not at call; justice divine
Mends not her slowest pace, for prayer, or cries.
Milton.

The best service they could do to the state, was to *mend* the lives of the persons who composed it.
Temple.

MICKLE.
MENANDER.
METASTASIO.
MERCATOR.
MERULA.
MERCURIALIS.
MENGS.
MEZERAI.
MEURSIUS.

When upon the sands the traveller
Sees the high sea come rolling from afar,
The land grow short, he *mends* his weary pace,
While death behind him covers all the place.
Dryden.

If, to avoid succession in eternal existence, they recur to the punctum stans of the schools, they will thereby very little *mend* the matter, or help us to a more positive idea of infinite duration. *Locke.*

Though in some lands the grass is but short, yet it *mends* garden herbs and fruit. *Mortimer's Husbandry.*

Name a new play and he's the poet's friend;
Nay, showed his faults—but when would poets *mend*?
Pope.

Their opinion of Wood, and his project, is not *mended*. *Swift.*

Happy the bard (if that fair name belong
To him that blends no fable with his song)
Whose lines uniting, by an honest art,
The faithful monitor's and poet's part,
Seek to delight, that they may *mend* mankind,
And, while they captivate, inform the mind.
Cowper.

MENDACITY, *n. s.* Lat. *mendax*. Falsehood.

In this delivery there were additional *mendacities*; for the commandment forbid not to touch the fruit, and positively said, Ye shall surely die; but she, extenuating, replied, Lest ye die. *Browne.*

MENDE, Auderitum, a very ancient town, and the principal place of the department of Lozère, in France. It has an inferior court of justice, under the jurisdiction of the royal court of Nîmes; a board of manufactures; a society of agriculture, and of arts and sciences; and a communal college. It is a post town, containing about 5500 inhabitants. This town is situated in the bottom of a delightful valley on the left bank of the river Lot, surrounded by mountains, from which descend numerous streams that water a great number of gardens and country seats in the neighbourhood. It is surrounded with a little boulevard, and is pretty well built; the streets, however, are narrow, but several public fountains contribute much to its cleanliness, and the freshness of its air. Among its manufactures may be particularly mentioned coarse cloth, serges, &c. A considerable trade is carried on in these articles, which are exported into Spain, Italy, Germany, and the interior of France. Here are a public library containing 6500 volumes, and a gallery of pictures. The cathedral is remarkable for its loftiness, and the bold architecture of its towers. The public fountain of the Griffon is particularly beautiful, and at a little distance from the town is the hermitage of St. Privast. Mende is situated fifty-seven miles distant south-east from St. Flour; sixty S.S.W. from Puy; ninety-three north from Montpelier, and 414 south from Paris.

MENDELSHON (Moses), or Moses the son of Mendal, a Jew of Berlin, and one of the most celebrated writers in Germany, born in 1728. His first attempt as an author was in 1755, by a work entitled Jerusalem; in which, besides other unjustifiable opinions, he maintains, that the Jews have a revealed law, but not a revealed religion; that opinions are not subjects of revelation; and that the only religion of the Jews is that of nature. He acquired great honor by his Phedon, or a Discourse on the Immateriality and Immortality of the Soul, translated into French in 1773; and was styled the Jewish Socrates by some periodical writers. His modest and obliging disposition gained him the esteem equally of the superstitious and of the incredulous. At his death he received from his nation those honors which are paid to their first rabbis. He greatly recommended himself by his integrity in business; but philosophy and literature were his principal occupation. His weak constitution being gradually impaired by intense application to study, he died in 1785, aged fifty-seven.

MENDEZ PINTO (Ferdinand), was born at Montemoro Velho, in Portugal. He embarked for India in 1537. His vessel being taken by the Turks, on his passage, he was carried to Mocra, and sold to a Greek renegado, and afterwards to a Jew; in whose possession he continued till he was redeemed by the governor of Ormus, a Portuguese fort; who procured him an opportunity of going out to India. During a residence of twenty-one years in that country, he was witness to very important transactions, and experienced many singular adventures. He returned to Portugal in 1558, where he enjoyed the reward of his labors, after having been thirteen times a slave, and sixteen times sold. A very curious account of his travels was written by himself, and published at Lisbon, A.D. 1614 in folio. It was translated into French by Bern Figuier, and printed at Paris, 1645, in 4to. It elucidates various particulars relating to the geography, history, and manners of the inhabitants of China, Japan, Pegu, Siam, Achem, Java, &c.

MEN'DICANT, *adj.* & *n. s.* Fr. *mendicant*; Lat. *mendicans*, *mendico*. Begging; poor to beggary: a beggar; one of the fraternity of beggars in the Romish church.

I am no whit afraid, O ye rich citizens, lest this paradox of our holy *mendicants* shall make you out of love with your wealth: I fear some of you would be rich though ye might not. *Bp. Hall.*

There is surely a physiognomy which master *mendicants* observe; whereby they instantly discover a merciful aspect, and will single out a face wherein they spy the signatures and marks of mercy.
Browne.

Be not righteous over much, is applicable to those who, out of an excess of zeal, practise mortifications, whereby they macerate their bodies; or to those who voluntarily reduce themselves to a poor and *mendicant* state. *Fiddes.*

What is station high?
'Tis a proud *mendicant*; it boasts and begs;
It begs an alms of homage from the throng,
And oft' the throng denies its charity. *Young.*

Digression is so much in modern use,
Thought is so rare, and fancy so profuse,
Some never seem so wide of their intent,
As when returning to the theme they meant;
As *mendicants*, whose business is to roam,
Make every parish but their own their home.
Cowper.

MENDICANTS, or begging friars, several orders of religious in Popish countries, who, having no settled revenues, are supported by the charitable contributions they receive from others. This class of society began in the thirteenth century, under Innocent III., who encouraged them as well as his successors. The members, by the

tenor of their institution, were to remain entirely destitute of all fixed revenues and possessions. But they at last increased to such an enormous multitude, that they became a burden not only to the people, but to the church itself. In a general council, therefore, assembled by Gregory X. at Lyons, in 1272, the mendicants were reduced to a smaller number, and confined to the four following societies, viz. the DOMINICANS, the FRANCISCANS, the CARMELITES, and the AUGUSTINES. (See these articles.) As the pontiffs allowed these four mendicant orders the liberty of travelling wherever they thought proper, of conversing with persons of every rank, of instructing the people wherever they went; and as those monks exhibited, in their manner of life, more striking marks of gravity and holiness than the other monastic societies, they arose to the summit of fame, and were regarded with the utmost veneration through all Europe. They were employed, not only in spiritual matters, but also in temporal and political affairs of the greatest consequence, in composing the differences of princes, concluding treaties of peace, concerting alliances, presiding in cabinet councils, governing courts, levying taxes, and other occupations, absolutely inconsistent with the monastic character and profession. However, the power of the Dominicans and Franciscans greatly surpassed that of the other two orders; insomuch that they were, before the Reformation, what the Jesuits have been since, the very soul of the hierarchy. At last their pride and confidence arrived at such a pitch, that they had the presumption to declare, that they had a divine commission to illustrate and maintain the religion of Jesus; that the true method of obtaining salvation was revealed to them alone; proclaiming the superior efficacy of their indulgences, and boasting their interest with the Supreme Being, the Virgin Mary, and the saints. By these impious wiles they so deluded the blinded multitude, that they would not entrust any but the mendicants with the care of their souls. Towards the close of the fourteenth century great numbers of both sexes requested admission into the order, as an infallible method of rendering heaven propitious. Many made it an essential part of their last wills, that their bodies after death should be wrapped in old ragged Dominican or Franciscan habits, and interred among the mendicants, to insure the divine mercy. But about the commencement of the fifteenth century they became the objects of general odium. Being, however, protected against all opposition by the popes, who regarded them as their most effectual supports, they suffered little from their numerous adversaries. Besides their arrogance, which was excessive, a quarrelsome and litigious spirit prevailed among them, and drew upon them justly the indignation of many. By affording refuge to the Beguines in their order they offended the bishops, and were thereby involved in difficulties of various kinds. They lost their credit in the sixteenth century by their rustic impudence, their ridiculous superstitions, their ignorance, cruelty, and brutish manners. They discovered the most barbarous aversion to the sciences, and to learned men, who endeavoured to open the paths of science to the pursuits of the studious youth, recommended the culture of the mind, and attacked the barbarism of the age in their writings and discourses. Their general character concurred with other circumstances to render a reformation desirable, and to accomplish this happy event. Among the number of Mendicants are also ranked the Capuchins, Recollects, Minims, and other branches from them. Buchanan tells us, the mendicants in Scotland, under an appearance of beggary, lived a very luxurious life; whence one wittily called them, not Mendicant but Manducant friars.

MENDOZA (Gonzales Peter de), a Spanish cardinal, born in 1428. He was an eminent statesman, and obtained the hat from Sixtus IV. He translated Homer and Virgil into Spanish, and died in 1495.

MENDOZA (John Gonzales de), an Augustine friar of Castile, who was ambassador from the king of Spain to the emperor of China. In 1593 he was made bishop of Lipari in Italy; in 1607 of Chiapa in New Spain; and in 1608 of Papaian in the West Indies. He wrote a history of China in Spanish, which has been translated into several languages.

MENDOZA, a city of Buenos Ayres, in the province of Cuyo, at the foot of the Andes. The neighbourhood is full of plantations watered by canals. It contains four convents, a Jesuits' college, and a church. A silver mine having been lately opened in its vicinity, the number of inhabitants is increasing, and at present amount to about 6000, employed in these works, or in carrying on a productive trade in fruits, wool, and wine. The river Mendoza flows by this town, which is fifty leagues from Santiago in Chili, and the district contains two silver, one copper, and one lead mine. Long. 69° 47 W., lat. 33° 25′ S.

MENDOZA, a large river of Buenos Ayres, in the province of Cuyo, which rises in the eastern slope of the Andes, and, running east, is formed into lakes in the plains; whence it issues under the name of Desaguero, and finally enters the Atlantic under the name of Colorado.

MENDRAH, a district and town of Fezzan, in Africa, with a soil generally hard and barren; but the quantity of trona, a species of fossil alkali, used in Morocco as an ingredient in the red dye of the leather, settles on the banks of numerous smoky lakes, and gives it a commercial importance. Great quantities of it are brought by the Fezzan merchants and shipped at Tripoli.

MENDS. For AMENDS, which see.

Let her be as she is: If she be fair, 'tis the better for her: and if she be not, she has the *mends* in her own hands. *Shakspeare.*

MENECRATES, a physician of Syracuse, who flourished about A. A. C. 360, famous for his skill in his profession, but much more for his vanity. He affected the character and attributes of Jupiter; made his patients follow him in those of the other gods, and travelled through different countries, escorted by these counterfeit deities. He once wrote to the king of Macedon, 'Menecrates Jupiter to Philip, greeting. Thou reignest in

Macedonia, and I in medicine; thou givest death to those who are in good health, I restore life to the sick; thy guard is composed of Macedonians; the gods themselves constitute mine.' Philip answered that he wished him restored to reason. Hearing afterwards that he was in Macedon, Philip sent for him, and invited him to an entertainment. Menecrates and his companions were placed on rich and lofty couches; before which was an altar, covered with the first fruits of the harvest: and, whilst an excellent repast was served up to the other guests, perfumes and libations only were offered to these new gods, who, greatly affronted, hastily left the palace, and never returned.

MENEDEMUS, a Greek philosopher, born at Erythreum, was the son of Callisthenes, and one of Phedo's followers. He was in the greatest esteem, and enjoyed several important posts in his own country. He several times defended Erythreum with great bravery, and died of grief when Antigonus conquered it. He flourished about 300 B. C.

MENELAUS, the son of Atreus, and brother of Agamemnon, reigned at Sparta, when Paris deprived him of his wife Helen. This rape occasioned the famous war of Troy. See Helen, and Paris.

Menelaus, a mathematician in the reign of Trajan, who wrote three books on the Sphere, which have been published by Marsenne.

MENES, the founder of the Egyptian monarchy, was born at This, a town of Thebias, in Upper Egypt. He had three sons, viz. Athotis, who ruled after him at This and Thebes; Curudes, who in Lower Egypt founded the kingdom of Heliopolis, which was afterwards that of Diospolis; and Necherophes, who reigned at Memphis. It is supposed that Menes reigned 117 years after the birth of Peleg, son of Heber, which was the year of the dispersion of mankind throughout the earth. In building Memphis he stopped the Nile near it, by a causeway 100 furlongs broad, and caused it to run through the mountains. Sir Isaac Newton makes Menes the same with Amenophis. See Ethiopia. Others make him the same with Mizraim.

MENESTRIER (John Baptist le), a native of Dijon, one of the most learned French antiquaries of his time. He wrote, 1. A Treatise on the medals, money, and ancient monuments of the Roman Empresses, in folio: 2. The most famous medals of the ancient Roman emperors and empresses in 4to. He died in 1634, aged seventy.

MENGS (Anthony Raphael), first painter to the king of Spain, was born at Auing in Bohemia, A. D. 1728. His father, painter to Augustus III. king of Poland, perceiving his superior talents, carried him from Dresden to Rome in 1741. Having copied the principal monuments of that capital, he returned in 1744 to Dresden, where he executed different works for Augustus with great success. During his stay in Italy he became acquainted with Charles, king of Naples; who, when he succeeded to the crown of Spain in 1761, engaged Mengs in his service, by granting him a pension of 2000 doubloons, with a house and equipage. He lived, however, chiefly at Rome; where, in 1779, he fell a sacrifice to his confidence in a German quack, who pretended to cure him of a disease which he had contracted, partly by intense application, and partly by grief for the loss of his wife. His manners were simple; he was a fond husband and a kind father; but his faults were want of economy and unbounded generosity. Although he received during the last eighteen years of his life above 250,000 livres, he hardly left wherewithal to defray his funeral charges. The king of Spain adopted his five daughters, and granted pensions to his two sons. His chief paintings are at Madrid and at Rome. A catalogue of them is to be found in the account of his life prefixed to his works, in 2 vols. 4to., published at Parma in 1780 by Chevalier d'Azara. These contain, 1. Reflections on the Beautiful, and on Taste in Painting. 2. Reflections on Raphael, Correggio, Titian, &c. 3.. On the cultivation of the Fine Arts in Spain. 4. Two Letters on the Group of Niobe. 5. A Letter on the Origin, Progress, &c., of Drawing. 6. A Letter on the principal Paintings at Madrid. 7. Memoirs of Correggio. 8. Memoirs of the Academy of Fine Arts at Madrid. 9. Practical Lessons in Painting. He formed his style upon the different excellencies of Raphael, Correggio, and Titian.

ME'NIAL, *adj.* & *n. s.* From Meiny, which see. Belonging to a retinue or train of servants: a servant of low order.

Two *menial* dogs before their master pressed;
Thus clad, and guarded thus, he seeks his kingly guest. *Dryden's Æneid.*

Hard is the fate of the infirm and poor!
Here, as I craved a morsel of their bread,
A pampered *menial* drove me from the door,
To seek a shelter in a humble shed. *Moss.*

The women attendants perform only the most *menial* offices. *Gulliver's Travels.*

MENIN, a handsome fortified town of Flanders, seated on the small river Lys. It has often changed masters; having been taken by the French in 1667, and fortified very strongly by Vauban; retaken by the allies in 1706, and ceded to the house of Austria by the treaty of Utrecht, but recovered in 1744 by the French, who demolished its fortifications. It was restored to Austria by the treaty of Aix-la-Chapelle; but was taken by the French republicans under Pichegru, April 30th, 1794, and annexed to France in 1795. It is well built, and its four principal streets, terminated by as many gates, meet in a square. Here are manufactures of lace, table linen, and silk stuffs; oil, soap, and tobacco. The bleaching fields are extensive, and it has two well attended annual fairs. Population 4600. It is eleven miles north of Lisle, and thirty south of Bruges.

MENIN'GES, *n. s.* Gr. μενιγγος. The two membranes that envelop the brain, and which are otherwise called the pia mater and dura mater.

The brain, being exposed to the air, groweth fluid, and is thrust forth by the contraction of the *meninges.* *Wiseman.*

MENINSKI, or Menin (Francis), or Francis à Mesgnien, a learned orientalist, born in Lorrain in 1623. He travelled to the east, and for

his skill in the oriental languages was made interpreter and counsellor of war to the emperor of Germany. He wrote a dictionary, entitled Thesaurus Linguarum Orientalium, printed at Vienna in 5 vols. folio, 1680 and 1687. He died at Vienna in 1698.

MENIPPEAN SATIRE, MENIPPEA SATIRA, a kind of satire consisting of prose and verse intermixed; so called from Menippus. Varro wrote satires under the title of Satiræ Menippeæ; whence this satire is also called Varronian satire. Among the moderns, a famous piece under this title was published in 1594, against the chiefs of the league, called also the Catholicon of Spain. It is esteemed a master-piece.

MENIPPUS, a cynic philosopher of Phœnicia. He was originally a slave, but purchased his liberty, and became one of the greatest usurers at Thebes. He wrote thirteen books of satires, which have been lost; and at last killed himself.

MENISPERMUM, moonseed, a genus of the decandria order, diœcia class of plants; natural order eleventh, sarmentaceæ: male has four exterior and eight interior petals; there are sixteen stamina; the corolla of the female is the same as in the male; there are eight barren stamina, and two monospermous berries. There are three species, all climbing plants, rising fourteen feet high, and natives of warm climates, but not remarkable for beauty. Of these the

M. cocculus grows in the Levant. The seeds formed into a paste are regarded as specific against lice and cutaneous eruptions. The same paste is likewise used for intoxicating fishes.

MENNO (Simon), the founder of the sect of the Mennonites, was born at Witmarsum, a village near Bolswert, in Friesland, in 1505, and died in 1561 in the duchy of Holstein, at the country seat of a certain nobleman near the city of Oldesloe, who moved with compassion by the perils to which Menno was exposed, and the snares that were daily laid for his ruin, took him, with certain of his associates, into his protection, and gave him an asylum. The writings of Menno, which are almost all written in the Dutch language, were published in folio at Amsterdam in 1651. About 1537 Menno was earnestly solicited by many of his sect to assume the rank and functions of a public teacher; and, as he considered those who made this proposal to be exempt from the fanatical phrenzy of their brethren at Munster, he yielded to their entreaties. From this period to the end of his life he travelled from one country to another, with his wife and children, exercising his ministry, under calamities of various kinds, that succeeded each other without interruption, and constantly exposed to the danger of falling a victim to the severity of the laws. East and West Friesland, with the province of Groningen, were first visited by this zealous apostle of the Anabaptists; whence he directed his course into Holland, Guelderland, Brabant, Westphalia, and the German provinces on the coasts of the Baltic, and penetrated as far as Livonia. In all these places his ministerial labours were attended with remarkable success, and added to his sect a prodigious number of followers. He was a man of genius, directed by a very sound judgment; he possessed a natural and persuasive eloquence, and such a degree of learning as made him pass for an oracle with the multitude. He appears also to have been a man of probity, of a meek spirit, gentle in his manners, pliable and obsequious with persons of all ranks, and extremely zealous in promoting practical religion and virtue, which he recommended both by example and precepts. The plan of discipline drawn up by Menno was much more mild and moderate than that of the furious and fanatical Anabaptists, but somewhat more severe, though more clear and consistent, than that of those branches of the sect who aimed at nothing more than the restoration of the Christian church to its primitive purity. Accordingly he condemned the plan of ecclesiastical discipline, that was founded on the prospect of a new kingdom, to be miraculously established by Jesus Christ on the ruins of civil government and the destruction of human rulers, and which had been the fatal source of dreadful commotions, execrable rebellions, and enormous crimes. He expressed his abhorrence of the licentious tenets, which several Anabaptists had maintained, with respect to polygamy and divorce; as well as some of their fanatical tenets about predictions, visions, &c. He retained indeed the doctrines commonly received among the Baptists of the present day, in relation to the baptism of infants, the connexion of the church with the state, and the abolition of war. These doctrines the eloquence of Menno set off to such advantage, that he acquired a high degree of credit among the Anabaptists; in consequence of which the different sects agreed in excluding from their communion the fanatics that dishonored them, and in renouncing all tenets detrimental to the authority of civil government.

MENNONITES, a sect in the United Provinces, which had its rise in 1536, when Menno Simon, who had been a Romish priest, and a notorious profligate, resigned his rank and office in the Romish church, and publicly embraced the communion of the Baptists. Though the Mennonites usually pass for a sect of Anabaptists, yet M. Herman Schyn, a Mennonite minister, who has published their history and apology, maintains, that they were not Anabaptists either in principle or by origin. However, nothing is more certain, than that the first Mennonite congregations were composed of different sects of Anabaptists, both of those who had been always inoffensive, and of those who, before their conversion by Menno, had been seditious fanatics. The Mennonites are subdivided into several sects; whereof the two principal are the Flanderians or Flemingians, and the Waterlandians. The opinions, says Mosheim, that are held in common by the Mennonites, seem to be all derived from this fundamental principle, that the kingdom which Christ established upon earth is a visible church or community, into which the holy and just alone are to be admitted, and which is exempt from all those institutions and rules of discipline that have been invented by human wisdom, for the correction and reformation of the wicked. They admit none to the sacrament of baptism, but such as are come to the full use of their reason; they neither admit civil rulers into their

communion, nor allow any of their members to perform the functions of magistracy; they deny the lawfulness of repelling force by force, and consider war, in all its shapes, as unchristian and unjust; they entertain the utmost aversion to the execution of justice, and more especially to capital punishment; and they refuse to confirm their testimony by an oath. The particular sentiments that divide the more considerable societies of the Mennonites are the following: The rigid Mennonites, called Flemingians, maintain the opinions of their founder as to the human nature of Christ, alledging that it was produced in the womb of the Virgin by the creating power of the Holy Ghost; the obligation to wash the feet of strangers; the necessity of excommunicating and avoiding, not only avowed sinners, but also all those who depart, even in light instances, as dress, &c., from the simplicity of their ancestors; the contempt due to human learning, and other matters of less moment. However, this austere system declines, and the rigid Mennonites are gradually approaching towards the opinions and discipline of the more moderate or Waterlandians. The first settlement of the Mennonites, in the United provinces, was granted them by William I. prince of Orange, about the close of the sixteenth century; but their liberty and tranquillity were not fixed upon solid foundations, till, by a confession of faith published in 1626, they cleared themselves from the imputation of those detestable errors that had been laid to their charge. To appease their intestine discords a considerable part of the Anabaptists of Flanders, Germany, and Friesland, held a conference at Amsterdam in 1630, and entered into bonds of fraternal communion, each reserving to themselves a liberty of retaining certain opinions. This association was renewed and confirmed by new resolutions in 1649; in consequence of which the rigorous laws of Menno were mitigated and corrected.

MENOCHIA, or Menochius (James), a celebrated lawyer, born at Pavia, but who became so skilful in the law, that he was called the Baldus and Bartholus of his age; all the princes of Italy soliciting him to their universities. He read at Padua twenty-three years, but from love of his country removed to Pavia, and succeeded Nicholas Gratiani. He acquired fame by his works, De Recuperandâ Possessione; De Adipiscendâ Possessione; De Præsumptionibus; De Arbitrariis Judicum Quæstionibus, et Causis Concilicrum, tom. 13, &c. He died in 1607, aged seventy-five.

MENOL'OGY, *n. s.* Fr. *menologe*; Gr. *μηνολογιον*, of *μηνη*, the moon, and *λογος*, a discourse. A register of months.

In the Roman martyrology we find, at one time, many thousand martyrs destroyed by Dioclesian: the *menology* saith they were twenty thousand.

Stillingfleet.

MENOU (James Francis, baron de), a modern French general and politician, was originally a deputy from the nobility of Touraine to the states-general, and one of the first of his order who entered into the commons' chamber. At this time he united himself with the duke of Orleans and the Jacobins, and was employed as mareschal-de-camp at Paris on the 10th of August, 1792. In 1793 he was sent against the insurgents of La Vendée, as general-in-chief, when he displayed great incapacity and was beaten by La Roche-Jacquelin. He was now superseded and returned to Paris. Having the command of a division, he defended the National Convention, in May 1795, against the Jacobins; but on a subsequent occasion his conduct exposed him to a degree of accusation as a traitor: he was however acquitted. He accompanied Buonaparte to Egypt, as general of a division, in which post he displayed considerable talents, but the same deficiency of principle as in earlier life. He turned Mahometan, for the sake of obtaining in marriage the daughter of the keeper of the baths of Rosetta, who was rich; submitted to the peculiar rites of Islamism, and called himself Abdallah James Menou. On Kleber being assassinated, he assumed the chief command, and was opposed to the English under general Abercromby; but he was at length obliged to capitulate, and returned to France in May 1802; Buonaparte immediately appointed him governor of Piedmont he was afterwards sent in a similar character to Venice, where he died August 13th, 1810.

MEN'SAL, *adj.* Lat. *mensalis.* Of or belonging to the table; transacted at table.

Conversation either mental or *mensal.* *Clarissa.*

MENSES, or Catamenia, in medicine, the monthly evacuations from the uterus of women not with child or not giving suck, so called from mensis, month, the period wherein they return. See Midwifery. By the Jewish law a woman was unclean while the menstrual blood flowed. See Lev. xv. 11—29.

The discharge of the menses is interrupted naturally during pregnancy: but this is not always the case, because some have them three months, some six months, and some during the whole time of gestation, though in less quantity than at other times. The menses are also mostly interrupted during the time of giving suck; though many women have a return about the third or fourth month after delivery, and almost all have them again in the ninth or tenth month. In cases of obstruction, the menstrual blood has discharged itself by other outlets. This periodical discharge ceases between forty and fifty; and the season in which this takes place is critical to the sex. However, those who survive this period without contracting any chronical disease, become more healthy and vigorous than they were before. When the menses are about to go off, they appear for the most part irregularly both in time and quantity; once in a fortnight, three, five, or six weeks; sometimes very sparingly, at other times in immoderate quantities. See Medicine.

MENSORES, among the ancient Romans, harbingers, whose business it was to go before the emperor, and fix upon lodgings for him when he travelled into any of the provinces. They also marked out encampments, and assigned every regiment its post.

Mensores were also land-surveyors, architects, or appraisers of houses and public buildings. The distributors of provisions in the army were called mensores frumentarii. Mensores was also an name given to servants who waited at table.

MEN'STRUAL, *adj.* } Fr. *menstruel, men-*
MEN'STRUOUS, } *strues;* Lat. *menstruus,*
MEN'STRUUM, *n. s.* } *mensis,* of Gr. *μηνη*, the moon. Monthly; occurring once a month; pertaining to a menstruum: the several adjectives are particularly applied to the female habit: menstruum is defined below by Quincy and seems, as Dr. Johnson says, to be derived from some notion of the old chemists about the influence of the moon in the preparation of dissolvents. See PHYSIOLOGY AND MEDICINE.

O thou of late beloved,
Now like a *menstruous* woman art removed. *Sandys.*

The dissents of the *menstrual* or strong waters hinder the incorporation, as well as those of the mental. *Bacon.*

Enquire what is the proper *menstruum* to dissolve metal, what will touch upon the one and not upon the other, and what several *menstrua* will dissolve any metal. *Id.*

She turns all her globe to the sun, by moving in her *menstrual* orb, and enjoys night and day alternately, one day of hers being equal to fourteen days and nights of ours. *Bentley.*

All liquors are called *menstruums* which are used as dissolvents, or to extract the virtues of ingredients by infusion, or decoction. *Quincy.*

White metalline bodies must be excepted, which, by reason of their excessive density, seem to reflect almost all the light incident on their first superficies, unless by solution in *menstruums* they be reduced into very small particles, and then they become transparent. *Newton's Opticks.*

MENSURATION.

MEN'SURABLE, *adj.* } Lat. *mensura*, a mea-
MENSURABIL'ITY, *n. s.* } sure. Measurable:
MEN'SURAL, *adj.* } mensural is an un-
MEN'SURATE, *v. a.* } usual word for, relat-
MENSURA'TION, *n. s.* } ing to measure: mensurate, a verb, also seldom used, for to take measure or the dimensions of any thing: mensuration, the act, art, or habit of measuring.

We measure our time by law and not by nature. The solar month is no periodical motion, and not easily *mensurable*, and the months unequal among themselves, and not to be measured by even weeks or days. *Holder.*

After giving the *mensuration* and argumentation of Dr. Cumberland, it would not have been fair to have suppressed those of another prelate. *Arbuthnot.*

MENSURATION is that branch of mathematics by which the relative extents of the spaces occupied by bodies are compared with each other; the comparison being always made with reference to some recognised unit of measure; as in length, a foot, a yard, &c.; in surface, a square inch, a square foot, or any other unit of surface; in solids, a solid inch, foot, or any other understood unit of the same kind; each kind of magnitude having its appropriate unit of measure.

This branch of mathematical science, from its extensive use in every department of life, must be considered as one of the most valuable and important of all the applications of abstract science. It rests for its principle in geometry and arithmetic, with the former of which it was indeed anciently considered as identical.

It has generally been considered that it took its rise as a separate branch of science in Egypt, where, the periodical overflowings of the Nile obliterating every year the marks which indicated the boundaries of property, it was necessary to have some precise method of re-allotting to each individual his share of land on the subsiding of the waters.

The elements of Euclid were probably compiled at first with reference to mensuration alone; as it may be observed that the different trains of reasoning in that admirable compendium, point always, in the end, to the means of measuring some body or figure, or of comparing them with others of a like kind. Thus the first book closes with the means of finding one square that shall be equal to two others; the second with finding a square equal to any given rectilineal figure. His elements afford the means of determining the areas of all rectilineal figures, and of comparing the areas of circles, and the solidities of spheres with each other; but to determine the relation which a circle has to a square, or a sphere to a cube, is a problem which, simple as it may seem, has to the present moment been only approximately determined.

Archimedes contributed greatly to the advancement of mensuration. He found that though the circle could not be squared, there were curvilinear figures that could be squared; and he observed that the parabola was exactly two-thirds of its circumscribing rectangle. He discovered many of the most curious properties of conic sections, and determined the ratio of spheres, spheroids, and conoids to their circumscribing cylinders, and pointed out for the first time, that all that was necessary to complete the quadrature of the circle was to find the ratio of its diameter to its circumference. He also gave the first approximation to this ratio, finding that the diameter to the circumference was nearly as 7 to 22; and consequently that the area of the circle was to that of its circumscribing square nearly as 11 to 14. Since the invention of fluxions these rough approximations have been superseded by others approaching so near the truth, that in a practical point of view nothing would be gained by carrying the approximation further.

The next great step in the improvement of mensuration was made by Cabalerius, who first introduced the idea that a circle might be considered as a polygon of an infinite number of infinitely small sides; that solids were composed of an infinite number of infinitely thin sections. Viewing the figures about which mensuration is conversant in this way, many difficult problems admitted of neat and simple solutions, though the metaphysics of the method are not such as can fully satisfy a geometrician. But Huygens, Walter, and Gregory, made many of their discoveries by the application of this method; which is now, in

the more difficult departments, quite superseded by the doctrine of fluxions. The discovery of fluxions revived among mathematicians the hope of effecting the quadrature of the circle; but the fluent of the fluxion which represented its area in terms of its diameter was found to be one which could only be approximately found.

Mathematicians have since applied themselves very sedulously and successfully to finding the most convenient series, for approximating to the lengths and area of different curves and curvilinear figures. The most complete treatise on mensuration, in all its branches, is that by Dr. Hutton, entitled a Complete Treatise on Mensuration, originally published at Newcastle in a quarto volume, but since in the octavo size. Dr. Hutton also published a practical work on the subject, being an abridgment of his larger one; and Mr. Bonnycastle published a neat and valuable compendium of the practical rules and formulæ, with their investigations and application. An exceedingly compact and complete little work on the subject has also been recently given to the public by Mr. Ingram.

Of the Mensuration of Superficies.

Problem I. *To find the area of a parallelogram.*

Rule 1.—Multiply the length by the perpendicular height, and the product will be the area.

Example.—What is the area of a rhombus whose side is 12·24 feet, and height 9·16 feet?

$12 \cdot 24 \times 9 \cdot 16 = 112 \cdot 1184$ feet. Answer.

Rule 2.—Multiply the product of two adjacent sides by the natural sine of their included angle, for the area.

Example.—What is the area of a parallelogram whose sides are 25·35 and 10·4 chains, and the included angle 30°?

Acres.

$25 \cdot 35 \times 10 \cdot 4 \times$ nat. sin. $30° = 13 \cdot 1820 =$
A. R. P.
13 : 0 : 29.

Prob. II. *To find the area of a triangle.*

Rule 1.—Multiply the base by the perpendicular let fall on it from the opposite angle and half the product will be the area.

Example.—What is the area of a triangle whose base is twenty feet and altitude 10·25?

$$\frac{20 \times 10 \cdot 25}{2} = 102 \cdot 5. \text{ Answer.}$$

Rule 2.—Multiply the product of two of the sides, by half the natural sine of their included angle.

Example.—What is the area of a triangle, of which two sides are 30 and 40, and their included angle 28° 57·3′?

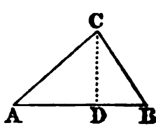
$$\frac{30 \times 40 \times \sin. 28° 57 \cdot 3'}{2} = 290 \cdot 47356.$$

The above rules are immediate consequences of the elementary principles of geometry and trigonometry.

Prob. III. *To find the area of a triangle, of which the sides only are given.*

Rule.—From half the sum of the three sides subtract each side separately, and multiply the half sum and the three remainders continually together; and the square root of the product will be the area.

Demonstration.—Let a, b, and c, represent respectively the sides BC, AC, and AB, of the triangle ABC, CD being the perpendicular. Then by geometry $c : b + a :: b - a : \overline{AD - DB} = \frac{b^2 - a^2}{c}$; hence $AD = \frac{c}{2} + \frac{b^2 - a^2}{2c} = \frac{c^2 + b^2 - a^2}{2c}$. But $CD^2 = \overline{AC + AD} \cdot \overline{AC - AD} = \left(b + \frac{c^2 + b^2 - a^2}{2c}\right) \cdot \left(b - \frac{c^2 + b^2 - a^2}{2c}\right) = \frac{\overline{b + c}|^2 - a^2}{2c} \cdot \frac{a^2 - \overline{b - c}|^2}{2c}$, whence $CD = \frac{1}{2c}\sqrt{(\overline{b + c}|^2 - a^2) \cdot (a^2 - \overline{b - c}|^2)}$ and the area $\frac{AB \cdot CD}{2} = \frac{1}{4}\sqrt{(\overline{b + c}|^2 - a^2) \cdot (a^2 - \overline{b - c}|^2)} = \sqrt{\frac{a + b + c}{2} \cdot \frac{a + b - c}{2} \cdot \frac{a - b + c}{2} \cdot \frac{b + c - a}{2}}$.



Example.—What is the area of a triangle whose sides are twenty, thirty, and forty feet?

$$\sqrt{\frac{20 + 30 + 40}{2} \cdot \frac{20 + 30 - 40}{2} \cdot \frac{20 + 40 - 30}{2} \cdot \frac{30 + 40 - 20}{2}} = 290 \cdot 4737. \text{ Answer.}$$

This rule may be conveniently performed by logarithms.

If S represent half the sum of a, b, and c, the three sides of the triangle, then

$$\frac{\log. S + \log. \overline{S - a} + \log. \overline{S - b} + \log. \overline{S - c}}{2} = \log. \text{ area.}$$

Prob. IV. *To find the area of a trapezium.*

Rule.—Divide it into two triangles by drawing a diagonal, and find the area of each triangle separately, and their sum will be the area of the trapezium; or multiply the diagonal by half the sum of the perpendiculars falling upon it from the opposite angles, and half the product will be the area.

Example.—What is the area of a trapezium whose diagonal is 80·5, and perpendiculars 24·5 and 30·1 respectively?

$$80 \cdot 5 \times \frac{24 \cdot 5 + 30 \cdot 1}{2} = 2197 \cdot 65. \text{ Answer.}$$

Prob. V. *To find the area of a trapezoid.*

Rule.—Divide it into two triangles by drawing

a diagonal to the two opposite angles, as in the trapezium, and the sum of their areas will be the area of the trapezoid. Or multiply the sum of the two parallel sides, by half the perpendicular distance for the area.

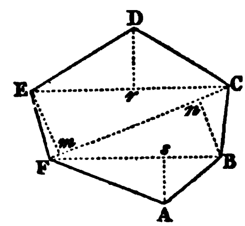
Example.—What is the area of a trapezoid whose parallel sides are 750 and 1225 feet, and perpendicular distance 1540 feet.

$$\overline{750 + 1225} \cdot \frac{1540}{2}. \text{ Answer.}$$

PROB. VI. *To find the area of an irregular rectilineal figure of any number of sides.*

Rule 1.—Divide the figure into triangles and trapeziums, and find the areas of each of them separately by the preceding rules, and the sum of these areas will be the area of the whole figure.

Example.—What is the area of the rectilineal figure A B C D E F, the dimensions being as follows: $FB = 20\cdot75$, $FC = 27\cdot48$, $EC = 18\cdot5$, $Bn = 14\cdot25$, $Em = 9\cdot35$, $Dr = 12\cdot8$, and $As = 8\cdot6$.



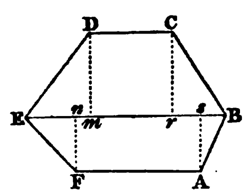
$$\frac{FB \,.\, As}{2} = 89\cdot225 = \text{area } \triangle\, ABF.$$

$$\frac{EC \,.\, Dr}{2} = 118\cdot400 = \quad DEC.$$

$$\frac{Bn + Em}{2} \,.\, FC = \frac{324.2640 = \text{trapezium FBCE.}}{531\cdot889 = \text{area of the whole figure.}}$$

Rule 2. The area of any irregular rectilineal figure may also be found by drawing perpendiculars from all its angles, on one of its diagonals, considered as a base; and then adding the areas of all the triangles and trapezoids togethrer for the content.

Example.—What is the area of the figure A B C D E F, the following being its dimensions: En 4·54, Em 8·26, Er 20·01, Es 26·22, EB 30·15, Dm 10·56, Cr 12·24, Fn 8·56, and As 9·26?



$$\frac{Fm \,.\, En}{2} = 19\cdot4312 = \text{area of } \triangle\, EFn$$

$$\frac{Dm \,.\, Em}{2} = 43\cdot6128 = \quad . \quad . \; EDm$$

$$\frac{Cr \,.\, Br}{2} = 62\cdot0568 = \quad . \quad . \; CBr$$

$$\frac{As \,.\, Bs}{2} = 18\cdot1959 = \quad . \quad . \; ABs$$

$$\frac{(Dm + Cr) \,.\, mr}{2} = 133\cdot9500 = \text{trap. } Cm$$

$$\frac{(En + As) \,.\, ns}{2} = 193\cdot1688 = \quad Fs$$

Sum $\overline{470\cdot4155}$ Answer.

PROB. VII. *To find the area of a regular polygon.*

Rule.—Multiply the square of the side of the polygon by the number standing opposite to its name in the following table, and the product will be the area.

Note.—The areas in the table are those of polygons whose sides are unity.

No. of sides.	Areas or Multipliers.
3	0·4330127
4	1·0000000
5	1·7204774
6	2·5980762
7	3·6339126
8	4·8284272
9	6·1818240
10	7·6942088
11	9·3656411
12	11·1961524

Example.—What is the area of a decagon, or regular polygon of 10 sides, each side being 16?
$7\cdot6942088 \times 16^2 = 196\cdot97174528$. Answer

Rule 2.—Multiply half the sum of the three sides by the perpendicular falling from the centre upon one of the sides, and the product will be the area.

Example.—What is the area of a hexagon, one of whose equal sides is 14·6 feet, and the perpendicular from its centre 12·64 feet?

$$\frac{6 \times 12\cdot64 \times 14\cdot6}{2} = 553\cdot632 \text{ square feet.}$$

Answer.

PROB. VIII. *To find the circumference of a circle, whose diameter is given, or the diameter when the circumference is given.*

Rule.—Multiply the diameter by 3·1416, and the product will be the circumference nearly; or divide the circumference by 3·1416, and the quotient will be the diameter nearly.

Demonstration.—It has been shown, in the article FLUXIONS, that $z =$ the arc of a circle, of which t is the tangent, the $z = t\left\{1 - \frac{t^2}{3r^2} + \frac{t^4}{5r^4} - \frac{t^6}{7r^6}\right.$, &c., in which if z be taken $= 45°$, and $r = 9$, we have $z = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9}$, &c.; and by collecting a sufficient number of terms, and multiplying by 8, we obtain the

circumference of a circle to radius 1 = 6·28318530; or the circumference to the diameter 1, = 3·14159265, to which 3·1416, the number used in the rule, is sufficiently near for ordinary purposes.

Note.—The diameter is to the circumference nearly as 7 to 22.

Example 1.—What is the circumference of a circle whose diameter is 7?

3·1416 × 7 = 21·9912. Answer.

PROB. IX. *To find the length of any arc of a circle.*

Rule.—From eight times the chord of half the arc subtract the chord of the whole arc, and one-third of the remainder will be the arc nearly.

Demonstration.—Let r = the radius, and s = the sine; then c, the chord of half the arc, will be $= \sqrt{s^2 + (r - \sqrt{r^2 - s^2})^2} = s - \frac{s^3}{8r^2} + \frac{7s^5}{128r^4}$; and eight times the chord $= 8s + \frac{s^3}{r^2} + \frac{7s^5}{16r^4}$; whence $\frac{8c - 2s}{3} = 2s + \frac{s^3}{3r^2} + \frac{7s^5}{48r^4}$. But the length of an arc whose sine is s, is known to be $s - \frac{s^3}{6r^2} + \frac{3s^5}{40r^4}$; whence twice that arc is $2s + \frac{s^3}{3r^2} + \frac{s^5}{20r^4}$, differing from the former only by $\frac{s^5}{240r^4}$, which shows the rule to be nearly true.

Example.—If the chord of the whole arc is 50·8, and that of half the arc 30·6, required the length of the arc?

$$\frac{30·6 \times 8 - 50·8}{3} = 66·6. \text{ Answer.}$$

PROB. X. *To find the area of a circle.*

Rule 1.—Multiply the circumference by the diameter, and the fourth part of the product will be the area.

Example.—What is the area of a circle whose radius is 15·25?

By PROB. VIII. the circumference is 2 × 15·25 × 3·1416; hence

$$\frac{2 \times 15·25 \times 3·1416 \times 30·}{4} = 730·6182.$$

Answer.

Rule 2.—Multiply the square of the diameter by ·7854; or the square of the circumference by ·07958; and the product in either case will be the area.

Example.—What is the area of a circle whose diameter is $7\frac{2}{3}$?

$(7\frac{2}{3})^2 \times ·7856 = 46·164$. Answer.

PROB. XI. *To find the area of the space included between two concentric circles.*

Rule.—Multiply the sum of their diameters by their difference, and this product by ·7854, and the result will be the required area.

Example.—Required the area of a ring, the diameters of whose boundary circles are 6 and 4?

$\overline{6 + 4} \,.\, \overline{6 - 4} \times ·7854 = 15·708$. Answer.

PROB. XII. *To find the area of a sector of a circle.*

Rule.—Let d = the diameter, c the chord of the arc, and v its versed sine, thus the area $= \frac{dc}{4} + \frac{c^3}{2\,.\,3\,.\,d^2}A + \frac{3^2 c^3}{4\,.\,5\,.\,d^2}B + \frac{5^2 c^3}{6\,.\,7\,.\,d^2}C'$, &c.; or $\frac{d\sqrt{dv}}{2} + \frac{v}{2\,.\,3\,.\,d}A + \frac{3^2 v}{4\,.\,5\,.\,d}B + \frac{5^2 v}{6\,.\,7\,d}C'$, &c.; whence A B and C represent the terms immediately preceding those where they first occur.

Example.—What is the area of a section whose height is 2, the diameter of the circle being 52?

$$\text{Here } \frac{d\sqrt{dv}}{2} = 26\sqrt{104} \qquad = 265·149014 \text{ (A).}$$

$$\frac{v}{2\,.\,3\,d}\ A = \frac{2}{6·52} \qquad A = \quad 1·699673 \text{ (B).}$$

$$\frac{3^2 v}{4\,.\,5\,.\,d}\ B = \frac{2·9}{20·52} \qquad B = \quad ·029417 \text{ (C).}$$

$$\frac{5^2 v}{6\,.\,7\,.\,d}\ C = \frac{2·25}{42·52} \qquad C = \quad ·000673 \text{ (D).}$$

$$\frac{7^2 v}{8 \cdot 9 \cdot d}\ D = \frac{2·49}{72·52} \qquad D = \quad 000018 \text{ (E).}$$

$$\frac{9^2 v}{10\,.\,11 \cdot d}\ E = \frac{2·81}{110·52} \qquad E = \quad 000001 \text{ (F).}$$

266·878796. Answer.

PROB. XIII. *To find the area of the segment of a circle.*

Rule.—The notation adopted in the preceding example being employed, the area of the segment is $= \frac{4v\sqrt{dv}}{3} - \frac{3v}{2\,.\,5\,.\,d}A - \frac{5v}{4\,.\,7\,.\,d}B - \frac{3\,.\,7v}{6 \cdot 9d}C - \frac{5\,.\,9v}{8\,.\,11\,.\,d}$, &c.

Example.—What is the area of a segment of a circle whose versed sine is 3, the diameter of the circle being 60?

Here $+\frac{12\sqrt{dv}}{3}$ $=$ A $=$ 53·665632

$-\frac{3v}{2\cdot5\cdot d}$ A $= -$B $= -$·804984

$-\frac{5v}{4.7.d}$ B $= -$C $= -$·007187

$-\frac{3.7v}{6.9\cdot d}$ C $= -$D $= -$·000139

$-\frac{5.9.v}{8.11.d}$ D $= -$E $= -$·000003

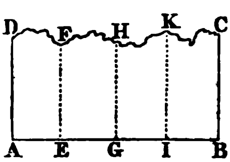
—·812313

Answer. 52·853319

Prob. XIV. *To find the area of a figure formed of right lines and curves.*

Practical Rule. — Take the perpendicular breadths of the figure in several places, at equal distances from each other, and divide their sum by the number of them for the mean breadth; and this mean breadth multiplied by the length of the figure will give the area nearly.

Example.—The perpendicular breadths of the irregular figure A B C D, at five equidistant places, A, E, G, I, B, are 9·2, 10·5, 8·3, 9·4, and 10·7; and its length A B is 20, what is its area?



$$\frac{9{\cdot}2 + 10{\cdot}5 + 8{\cdot}3 + 9{\cdot}4 + 10{\cdot}7}{5} \times 20 =$$

190·7500. Answer.

Prob. XV. *To find the circumference of an ellipse.*

Rule 1.—Multiply the square root of half the sum of the squares of the two diameters, and the product will be the circumference nearly.

Demonstration.—If $t =$ the transverse, c the conjugate, $p = 3{\cdot}1416$, and $d = 1 - \frac{c^2}{t^2}$; then, as may be shown by fluxions, $pt\left\{1 - \frac{d}{2.2} - \frac{3d^2}{2.2.44} - \frac{3.3.5.d^3}{2.2.4.4.66}\right.$, &c. $=$ the circumference. Now the above rule is $p\frac{\sqrt{t^2+c^2}}{2} = pt\sqrt{\frac{1}{2}+\frac{c^2}{2t^2}} = pt\sqrt{1-\frac{d}{2}} = pt$ $\left\{1 - \frac{d}{2\cdot2} - \frac{d^2}{2^3.4} - \frac{3d^3}{2^4.4.6}\right.$, differing from the former only by $\frac{d^3}{64}$.

Rule 2.—Multiply half the sum of the diameters by 3·1416, and the product will give the circumference exact enough for most practical purposes.

Example.—What is the circumference of an ellipse whose diameters are 24 and 20?

By *Rule* 1.—$\frac{24^2 + 20^2}{2} \times 3{\cdot}1416 = 69{\cdot}3979$. Answer.

Prob. XVI. *To find the area of an ellipse.*

Rule.—Multiply the transverse diameter by the conjugate, and the product again by 7854, and the result will be the area.

Exrmple.—If the axes of an ellipse be 70 and 50, what is its area?

$70 \times 50 \times {\cdot}7854 = 2748{\cdot}9$. Answer.

Prob. XVII.—*To find the area of any segment of an ellipse, the base of the segment being parallel to one of the diameters.*

Rule. Divide the height of the segment by the axis, of which it is a part, and find by Prob. XIII. the area of a circular segment, whose diameter is unity, and height the quotient produced by so dividing. Multiply this circular area by the product of the two axes of the ellipse, and the result will be the area of the segment.

Demonstration.—Call the transverse t, the conjugate c, the abscissa x, and the ordinate y; then (see Conics) $y = \frac{c}{t}(tx - x^2)^{\frac{1}{2}}$, whence the fluxion of the area is $\frac{c}{t} \times \dot{x}\,(tx - x^2)^{\frac{1}{2}}$. But $\dot{x}$ $(tx - x^2)^{\frac{1}{2}}$ is the fluxion of the corresponding circular segment, whose versed sign is x and diameter t. Denoting the fluent of this expression by F, we have the fluent of $\frac{c}{t} \times \dot{x}\,(tx - x^2)^{\frac{1}{2}} = \frac{c}{t}$. F; from which both this and the preceding rule are deduced.

Example.—What is the area of the elliptic segment whose height is 10, the axes being 35 and 25 respectively, the base of the segment being parallel to the minor axis?

Here $\frac{10}{35} = {\cdot}2857 =$ versed sine of corresponding circular segment to radius unity; whose area therefore is ·185135. Here $\cdot185135 \times 35 \times 25 = 161{\cdot}993125$, the required area.

Prob. XVIII. *To find the length of an arc of a parabola cut off by a double ordinate.*

Rule.—To the square of the ordinate add four-thirds of the square of the abscissa 1, and twice the square root of the sum will be the length of the arc nearly.

Demonstration.—It may easily be shown, by the aid of fluxions, that z being the arc, y the abscissa, and p the perimeter, $z = 2\cdot y\left\{1 + \frac{4}{2.3}\cdot\frac{y^2}{p^2} - \frac{4^2}{2.4.5}\cdot\frac{y^4}{p^4} + \frac{3.4^3}{2.4.6.7}\cdot\frac{y^6}{p^6}\right.$, &c.; and the above rule is $z = 2\sqrt{y^2 + \frac{4}{3}x^2} = 2\sqrt{y^2 + \frac{4}{3}\cdot\frac{y^4}{p^2}} = 2y\left\{1 + \frac{4}{2.3}\cdot\frac{y^2}{p^2} - \frac{4^2}{2.4.3^2}\cdot\frac{y^4}{p^4}\right.$, &c., which differs from the pre-

ceding by only four forty-fifths of a unit in the third term: and shows the rule therefore to be a close approximation.

Example.—The abscissa is 2, and its ordinate 6, what is the length of the parabolic arc?

$$2\sqrt{6^2 + \frac{4}{3} \cdot 2^2} = 2\sqrt{41 \cdot 3333} = 12 \cdot 858.$$

Answer.

PROB. XIX. *To find the area of a parabola.*

Rule.—Multiply the base by two-thirds of the height, and the product will be the area.

Demonstration.—The abscissa being x, the ordinate y, and the perimeter p, we have the fluxion of the area $= y\dot{x} = \dot{x}\sqrt{p x}$, and its fluent $= \frac{2x}{3} \times \sqrt{p x} = \frac{2x}{y} \cdot y$.

Example.—The abscissa being 12, and the double ordinate 38, what is the area?

$$38 \times \frac{2 \times 12}{3} = 304 \quad \text{Answer.}$$

PROB. XX. *To find the area of the frustum of a parabola.*

Rule.—Divide the difference of the cubes of the two ends of the frustum by the difference of the squares, and multiply the quotient by two-thirds of the breadth of the frustum for the area.

Demonstration.—Let D and d represent the length of the ends, and a the breadth; then by the nature of the curve $\frac{a D^2}{D^2 - d^2} =$ the abscissa reckoned from the vertex to the bottom of the frustum, and $\frac{a d^2}{D^2 - d^2} =$ the abscissa from the vertex to the top. Hence $\frac{2}{3} D \times \frac{a D^2}{D^2 - d^2} - \frac{2}{3} d \times \frac{a d^2}{D^2 - d^2} = \frac{2}{3} a \frac{D^3 - d^3}{D^2 - d^2}$, the required area.

PROB. XXI. *To find the length of an arc of an hyperbola.*

Rule.—To nineteen times the square of the transverse add twenty-one times the square of the conjugate; and to nine times the square of the transverse add twenty-one times the square of the conjugate; and multiply each sum by the abscissa. To each of the products add fifteen times the product of the transverse and the square of the conjugate. Then, as the less of these results is to the greater, so is the ordinate to the length of the arc nearly.

PROB. XXII. *To find the area of an hyperbola, the transverse conjugate and abscissa being given.*

Rule.—To the product of the transverse and abscissa add five-sevenths of the square of the abscissa, and multiply the square root of the sum by twenty-one. Add four times the square root of the product of the transverse and abscissa to the last product, and divide the sum by seventy-five. Then, if four times the product of the conjugate and abscissa be divided by the transverse, this last quotient multiplied by the former will give the area nearly.

ON THE MENSURATION OF SOLIDS.

PROB. XXIII. *To find the solidity of prisms and cylinders.*

Rule.—Multiply the area of the end by the perpendicular altitude, and the product will be the solidity.

Example.—What is the solidity of a prism whose base is a regular hexagon, each of the equal sides being one foot four inches, and the length fifteen feet?

By Prob. VII., $\overline{1\frac{1}{3}}^2 \times 2 \cdot 5980762 =$ the area of the end; hence $(1\frac{1}{3})^2 \times 2 \cdot 5980762 \times 15 =$ 69·282 feet. Answer.

PROB. XXIV. *To find the convex surface of an upright cylinder.*

Rule.—Multiply the circumference of the base by the height of the cylinder, and the product will be the convex surface required.

Example.—Required the convex surface of a cylinder whose diameter is thirty inches, and length sixty inches?

By Prob. VIII. $3 \cdot 1416 \times 30$ is the circumference; when $3 \cdot 1416 \times$ by $30 \times 60 = 5654 \cdot 862$, the required surface.

PROB. XXV. *To find the convex surface of a right cone or pyramid.*

Rule.—Multiply half the circumference of the base by the slant height, and the product will be the convex surface.

Example.—The circumference of the base is 10·75, and the slant height 18·25, what is the convex surface?

$$\frac{10 \cdot 75}{2} \times 18 \cdot 25 = 98 \cdot 09375 \text{ square feet.}$$

Answer.

PROB. XXV.* *To find the convex surface of the frustum of a right cone or pyramid.*

Rule.—Multiply half the sum of the perimeters of the two ends by the slant height of the frustum, and the product will be the area.

Example.—The circumferences of the ends of the frustum of a pyramid are thirty and ten feet, and its slant height twenty feet, required its convex surface.

$$\frac{30 + 10}{2} \times 20 = 400. \quad \text{Answer.}$$

Note. The demonstration of the three preceding rules is too simple to need any formal statement.

PROB. XXVI. *To find the solid content of a cone or pyramid.*

Rule.—Multiply the area of the base by the perpendicular height, and one-third of the product will be the solidity.

This rule is demonstrated in the article GEOMETRY.

Example.—Required the solidity of a hexagonal prism, each of its equal sides being forty, and its altitude sixty.

By Prob. VII. the area of its base is $40^2 \times 2 \cdot 5980762$; therefore $\frac{40^2 \times 2 \cdot 5980762 \times 60}{3} = 83138.432$. Answer.

PROB. XXVII. *To find the solidity of the frustum of a cone or pyramid.*

Rule 1.—For the frustum of a cone, the dia-

meters of the ends and the height being given. Divide the difference of the cubes of the diameters by the difference of the diameters, multiply the quotient by ·7856, and again by one-third of the height, and the result will be the solidity.

Rule 2. For the frustum of a pyramid when the sides of the base and the height are given. To the areas of the ends add the square root of their product, and multiply the sum by one-third of the height for the solidity.

Demonstration.—Let D and d be the greater and less diameters of the conical frustum, h the height, and $p = \cdot 7854$, then, $\frac{d\,h}{D - d} =$ the height of the part cut off from the top of the cone, and $h + \frac{d\,h}{D - d} =$ whole height of the cone. Hence, $\frac{p\,D^2}{3} \times \left(h + \frac{d\,h}{D - d}\right) - \frac{p\,d^2}{3} \times \frac{d\,h}{D - d} =$ the solidity of the frustum. This reduced, becomes $\frac{D^3 - d^3}{D - d} \cdot \frac{h\,p}{3}$; the rule for the cone. In a similar way is the rule for the pyramidal frustum demonstrated.

Example.—What is the solidity of the frustum of a cone, the diameter of the greater end being four feet, of the less end two feet, and altitude six feet?

$$\frac{4^3 - 2^3}{4 - 2} \cdot \frac{6 \times \cdot 7854}{3} = 65\cdot 9736. \text{ Answer}$$

PROB. XXVIII. *To find the solidity of a wedge.*

Rule.—Add twice the length of the base to the length of the edge; multiply the sum by the height of the wedge, and again by the breadth of the base, and one-sixth of the last product will be the solidity.

Demonstration.—Let L = length of the base, b its breadth, l the length of the edge, and h the height of the edge. Then by the preceding rule we have $\frac{b\,l\,h}{2} \pm b\,h \times \frac{\mp L \pm l}{3} = b\,h \times \frac{2\,L + l}{6}$.

Example.—How many solid feet are in a wedge whose base is sixty-four inches long and nine broad, the length of the edge being forty-two inches, and the perpendicular height twenty-eight inches?

$$\frac{(2 \times 64 + 42) \times 28 \times 9}{6} = 7140 \text{ solid inches,}$$

or 4·1319 solid feet.

PROB. XXIX. *To find the solidity of a prismoid.*

Rule.—To the sum of the areas of the two ends add four times the area of a section parallel to, and equally distant from, both ends, and multiply the sum by one-tenth of the height for the solidity.

Demonstration.— Let B = the breadth of the greater end, b = that of the less; L and l their lengths, and h their height; then, by the last problem, the solidity is $(\overline{2\,L + l}\,.\,B + \overline{2\,l + L}\,.\,b)\,.\,\frac{h}{6}$; which, by taking $M = \frac{L + l}{2}$ and $m = \frac{B + l}{2}$ becomes $(B\,L + b\,l + 4\,M\,m)\,\frac{h}{6}$; which is the rule.

Example.—The dimensions of a waggon are at top 81·5 inches by 55; and at bottom 41 inches by 29·5; and perpendicular depth 47·25, required its capacity?

$$\frac{81\cdot 5 \times 55 + 41 \times 29\cdot 5 + \overline{81\cdot 5 + 41} \times \overline{55 + 29\cdot 5}}{6} = 73\cdot 1133 \text{ cubic feet. Answer.}$$

PROB. XXX. *To find the convex surface of a sphere.*

Rule.—Multiply the diameter of the sphere by its circumference, and the product will be the convex surface.

Demonstration.—Let $p = 3\cdot 1416$, x the abscissa, y the ordinate, and z the corresponding arc, and $d =$ the diameter. Then by fluxions $2\,p\,y\,\dot{z}$ is the fluxion of the surface, and $\dot{z} = (\dot{x}^2 + \dot{y}^2)^{\frac{1}{2}}$, and by the property of the circle $\dot{y}^2 = \frac{\left(\frac{d}{2} - x\right)^2 \dot{x}^2}{d\,x - x^2}$ in substituting these values in the expression for the fluxion of the surface, reducing and taking the fluent we have $p\,d\,x$ for the surface of the segment whose height is x, which, when $x = d$, becomes $p\,d^2$, which is the rule.

Example.—What is the surface of a sphere whose diameter is 1⅓ feet, and circumference 4·1888 feet.

$$4\cdot 1888 \times \frac{4}{3} = 5\cdot 58506 \text{ square feet. Answer.}$$

PROB. XXXI. *To find the solidity of a sphere.*

Rule.—Multiply the centre of the diameter by ·5236, and the product will be the solidity.

Demonstration.—Adopting the notation in the preceding problem, we have $p\,d\,x\,\dot{x} - p\,x^2\,\dot{x}$ for the fluxion of the solidity, whose fluent gives $\frac{3\,p\,d\,x^2 - 2\,p\,x^3}{6}$ for the solidity of the segment whose altitude is x; and, when $x = d$, the expression becomes $\frac{p\,d^3}{6} = d^3 \times \cdot 5236$.

Example.—What is the solidity of the earth, supposing it a perfect sphere of 7957¾ miles diameter.

$(7957\frac{3}{4})^3 \times \cdot 5236 = 263858149120$ entire miles. Answer.

PROB. XXXII. *To find the solidity of the segment of a sphere.*

Rule.—To three times the square of the radius of its base add the square of its height, multiply the sum by the height, and by ·5236 for the solidity.

Demonstration.—By the last problem we had $(3\,d\,x^2 - r\,x^3)\,\frac{p}{6} =$ the solidity of the segment; and $\frac{r^2 + x^2}{x} = d$, r being the radius of the base of the segment; whence, by substitution and re-

duction, we have the solidity $= (3\,r^2 + h^2)\,\frac{p\,h}{6}$ which is the rule.

Example.—What is the solidity of a segment of a sphere, the diameter of whose base is twenty, and height nine?

$(3\,.\,\overline{10}^2 + 9^2) \times 9 \times \cdot 5236 = 1795\cdot 4246\cdot$ Answer.

PROB. XXXIII. *To find the solidity of a frustum or zone of a sphere.*

To the sum of the squares of the radii of two ends add one-third of the square of their distance; and multiply the sum by the breadth, and by 1·5708 for the solidity.

Demonstration.—Let H and h be the heights of the two segments of which the zone is the difference, and R, r, the radii of their bases; then by the last problem $\frac{p}{6}\left\{(3\,R^2\,H + H^3) - (3\,r^2\,h - h^3)\right\}$ is the solidity of the zone whose height is $H - h$. Hence, putting a for the altitude of the frustum, we have by substituting eliminating and reducing $\left(R^2 + r^2 + \frac{a^2}{3}\right)\frac{p}{2}$, which is the rule.

Example.—What is the solidity of a zone whose greater diameter is twenty-four inches, less twenty inches, and breadth four inches?

$\left(12^2 + 10^2 + \frac{4^2}{3}\right) \times 4 \times 1\cdot 5708 = 1566\cdot 6112$ inches. Answer.

PROB. XXXIV. *To find the solidity of a circular spindle, whose length and middle diameter are given.*

Rule.—From one-third of the cube of half the length of the spindle subtract the product of the central distance and half the area of the generating segment, and multiply the remainder by 12·5664 for the solidity.

PROB. XXXV. *To find the solidity of the middle frustum of a circular spindle, its length, middle diameter, and that of either of its ends, being given.*

Rule.—From the square of half the length of the spindle subtract one-third of the square of half the length of the frustum, and multiply the remainder by the half length. From the product take that of the area, and the central distance, and multiply the remainder by 6·2832, for the solidity.

PROB. XXXVI. *To find the solidity of a spheroid, its two axes being given.*

Rule.—Multiply the square of the revolving axis by the fixed axis, and the product again by ·5236 for the solidity.

PROB. XXXVII. *To find the solidity of the middle frustum of a spheroid, the dimensions of the frustum being given.*

Rule.—Case 1. When the ends are circular, or perpendicular to the fixed axis.—To twice the square of the middle diameter add the square of the diameter of either of the ends, and multiply the same by the length of the frustum, and by ·2618, and the result will be the solidity.

Case 2. When the ends are elliptical or perpendicular to the revolving axis.—Multiply twice the transverse diameter of the middle section by its conjugate diameter, and to this product add the product of the transverse and conjugate diameter of either of the ends. Multiply this sum by the length of the frustum, and by ·2618, and the product will be the solidity.

PROB. XXXVIII. *To find the solidity of the segment of a spheroid.*

Rule.—Case 1. When the base is perpendicular to the fixed axis.—Divide the square of the revolving axis by the square of the fixed axis, and multiply the quotient by the difference between three times the fixed axis and twice the height of the segment. Multiply this last product by the square of the height of the segment, and again by ·5236, and the result will be the solidity.

Case 2. When the base is perpendicular to the revolving axis.—Divide the fixed axis by the revolving axis, and multiply the quotient by the difference between three times the revolving axis and the height of the segment. Multiply the product by the square of the height of the segment, and again by ·5236, and it will give the solidity required.

PROB. XXXIX. *To find the solidity of a paraboloid.*

Rule.—Multiply the area of the base by the height, and half the product will be the solidity.

PROB. XL. *To find the solidity of the frustum of a paraboloid when its ends are perpendicular to the axis of the solid.*

Rule.—Multiply the sum of the squares of the diameters of the ends by the height of the frustum, and the product by ·3927, and it will give the solidity.

PROB. XLI. *To find the solidity of a parabolic spindle.*

Rule.—Multiply the square of the middle diameter by the length of the spindle, and the product by ·418879, and it will give the solidity.

PROB. XLII. *To find the solidity of the middle frustum of a parabolic spindle, whose dimensions are given.*

Rule.—To eight times the square of the middle diameter add three times the square of the less, and four times their product; multiply this sum by the length, and the product again by ·05236, and it will give the solidity.

PROB. XLIII. *To find the solidity of a hyperboloid.*

Rule.—As the sum of the transverse axis of the generating hyperbola and the height of the solid, is to the sum of the transverse axis and two-thirds of the height, so is half the area of the base, multiplied by the altitude, to the solidity of the hyperboloid.

PROB. XLIV. *To find the solidity of the frustum of a hyperboloid.*

Rule.—Add together the square of the greater and less semi-diameters, and square of the whole diameter in the middle; multiply the sum by the altitude, and by ·5236, for the solidity.

PROB. XLV.—*To find the surfaces and solidities of regular bodies.*

Rule 1.—Multiply the square of the lineai edge by the tabular area in the annexed table, and the product will be the superficies.

Rule 2.—Multiply the centre of the linear edge by the tabular solidity in the annexed table, and the product will be the solidity.

SURFACES AND SOLIDITIES OF REGULAR BODIES WHEN THE LOWER EDGE IS 1.

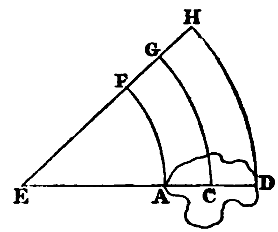
No. of Sides.	Surfaces.	Solidities.
4	1·73205	0·11785
6	6·00000	1·00000
8	3·46410	0·47140
12	20·64578	7·66312
20	8·66025	2·18169

The demonstrations of such of the preceding problems as want of room has obliged us to omit, may be seen in Bonnycastle's Treatise on Mensuration, before mentioned; with a copious collection of examples for exercises.

We shall close this article with an extract from Dr. Hutton's valuable work on Mensuration, on the relation between the areas of figures and the centres of gravity of their generating planes and lines, commonly called the centrobaric method.

Proportion.—If any line, straight or curved, or any plain figure, whether bounded by right lines or curves, revolve about an axis in the plane of the figure; the surface or solid generated will be equal to the surface or solid whose base is the given line or figure, and height the arc described by the centre of gravity of the said generating line or figure.

Demonstration.—Let AFHD be the figure generated by the given line or plane ACD; through C, the centre of gravity, of which draw DCAE perpendicular to the axis of revolution, and meeting HGFE in E, and let every point



of the base be reduced to AD by means of perpendiculars to it. The figure AFHD generated, is equal to all the AF's, CG's, &c., which are as all the EA's, FC's, &c., or as so many times EC, by the doctrine of mechanics. Hence the sum of all the AF's, CG's, &c., is equal to so many times CG, or equal to AD × CG; that is, the figure AFHD is equal to ABD × CG, or the base unto the line described by the centre of gravity.

By the application of this elegant principle, the areas and solidities of many surfaces and bodies, which may be conceived to be generated either by direct motion or revolution, may very readily be deduced.

MENTAL, *adj.* } Fr. *mentale*; Lat. *mens*, MEN'TALLY, *adv.* } *mentis*, the mind. Intellectual; of or relating to the mind: hence, not openly or externally.

What a *mental* power
This eye shoots forth! How big imagination
Moves in this lip! To the dumbness of the gesture
One might interpret. *Shakspeare. Timon of Athens.*

This beholding, therefore, is with *mental* eyes: and not with every sudden glance, but with deep considerations. *Bp. Hall.*

So deep the power of these ingredients pierced,
Even to the inmost seat of *mental* sight,
That Adam, now enforced to close his eyes,
Sunk down, and all his spirits became entranced.
Milton.

If the ideas be not innate, there was a time when the mind was without those principles; for, where the ideas are not, there can be no knowledge, no assent, no *mental* or verbal propositions about them. *Locke.*

The metaphor of taste would not have been so general, had there not been a conformity between the *mental* taste and that sensitive taste that affects the palate. *Addison.*

She kindly talked, at least three hours,
Of plastick forms, and *mental* powers. *Prior.*

If we consider the heart the first principle of life, and *mentally* divide it into its constituent parts, we find nothing but what is in any muscle of the body. *Bentley.*

Those inward representations of spirit, thought, love, and hatred, are pure and *mental* ideas, belonging to the mind, and carry nothing of shape or sense in them. *Watts.*

Unwise, who, tossing on the watery way,
All to the storm the unfettered sail devolve:
Man, more unwise, resigns the *mental* sway,
Borne headlong on by passion's keen resolve.
Beattie.

MENTHA, mint, in botany, a genus of the gymnospermia order, didynamia class of plants; natural order forty-second, verticillatæ: cor. nearly equal, and quadrifid, with one segment broader than the rest, and emarginated; the stamina are erect, standing asunder. There are many species, but not above three are cultivated for use; viz. 1. M. piperita, peppermint; 2. M. pulegium, pennyroyal; and, 3. M. viridis, common spearmint: all these are so well known as to need no description; and they are all very easily propagated by cuttings, parting the roots, or by off-sets.—For culinary purposes, the spearmint is preferable to the other two; but, for medicine, the peppermint and pennyroyal have in some places almost entirely superseded it. A conserve of the leaves is very grateful, and the distilled waters, both simple and spirituous, are universally thought pleasant. The leaves are used in spring salads; and the juice of them, boiled up with sugar, is formed into tablets. The virtues of mint are those of a warm stomachic and carminative: in loss of appetite, and nausea, there are few simples of equal efficacy. In colics, lienteries, and other immoderate fluxes, this plant frequently does good service. It likewise proves beneficial in many hysteric cases, and affords a useful cordial in languors and other weaknesses consequent upon delivery. The best preparation in these cases is a strong infusion of the dried herb in water which is much superior to the green, or rather a tincture or extract prepared with rectified spirit. These possess the whole virtues of the mint; the essential oil and distilled water contain only the aromatic part; the expressed juice only the astringency and bitterishness, together with the mucilaginous substance common to all vegetables. The peppermint is much more pungent than the others. Pennyroyal has the same general characters with mint, but is more acrid and less agreeable when taken into the stomach. It has long been held in great esteem as an aperient and deobstruent, particularly in hysteric complaints, and suppressions of the menses. For these purposes the distilled water is generally made use of, or, what is of equal efficacy, an infusion of the leaves.

MEN'TION, *n. s.* & *v. a.* Fr. *mention*, *mentionner*; Lat. *mentio*, a speaking of. Expression, oral or written; recital; hint: to express in words or writing.

MENTOR, son of Alcimus, the confidential friend of Ulysses, who intrusted to him the care of his domestic affairs, during his absence at the siege of Troy. The education of young Telemachus fell to his care, and when the prince set out in search of his father, Minerva accompanied him under the form of Mentor, as his counsellor and guide. From the development of this character in the Telemaque of Fenelon, the name Mentor is proverbially used to signify a wise and faithful monitor.

MENTZ, or MAYENCE, a strongly fortified city of the grand duchy of Hesse, and a bishop's see, is situated on the left bank of the Rhine, immediately below the confluence of the Maine with that river. It is built in the form of a semicircle, of which the Rhine is the base. Bastions with ravelins extend around the circumference; at the southern extremity is a citadel; at the northern two lunettes. On the south-west side are outworks of great strength, viz. six forts and a retrenched redoubt: most of them having casemates. On the north side, and beyond the glacis, are retrenchments thrown up in the latter half of the eighteenth century; and on the side of the river there is a bridge of boats, nearly half a mile in length, which crosses the Rhine to the village of Cassel, and is defended by a tete du pont. A little above this is an island formed by the Maine, and strongly fortified. On that river, about a mile above its junction with the Rhine, is the village of Costheim; and a little farther up a bridge of boats, defended by a strong tete du pont. These works require a garrison of nearly 30,000 men; but Mentz ranks, in consequence of them, as the strongest fortress in West Germany, if not in the whole empire.

Most of the streets of this old town are narrow, crooked, and gloomy, but some of the houses belonging to the great are spacious, and even stately. The buildings worth notice are, the electoral palace, now used as a military hospital, and greatly decayed; the house of the Teutonic knights, and the arsenal, all situated on the Rhine; and the houses of the Bassenheim, Stadion, Ostein, and Elz families. The dom or cathedral was built in the twelfth century; the church of St. Ignatius is a model of architecture, and ornamented with good ceiling paintings.

the ancient church of St. Stephen commands a fine view from the steeple. The public library has a collection of 80,000 volumes; cabinets of coins, medals, and natural history; a good collection of philosophical instruments; a fine museum of Roman monuments, and a picture gallery. Here are also a seminary, lyceum, and schools for medicine, midwifery, and the veterinary art.

The Eichelstein, a Roman monument, at a little distance from the town, is said to have been erected in honor of Drusus. It is now a mere ruin. Near Zahlbach, in this vicinity, is a Roman aqueduct; and along the banks of the Rhine a beautiful parade, and a quay or harbour for landing goods. The chief attraction of Mentz and its environs are the beautiful prospects to the south and west. Its trade in wines (French and Rhenish), and in general commission business connected with the navigation, is considerable, and largely conducted by Jews. Its manufacturing establishments are of small extent. The chief are cotton and coffee of chicory. Population 25,000.

The ancient and modern history of this city are alike interesting. Here Marcus Agrippa established an entrenched camp to oppose the German nations who menaced Gaul; and some time after Drusus Germanicus erected here a fort called Moguntiacum, and another on the opposite bank of the Rhine. Moguntiacum was extended, till the great struggles between the Romans and Germans checked its prosperity, but it traces its restoration to Charlemagne, who erected here a metropolitan church. Trade first beginning to thrive on the Rhine in the thirteenth century, the magistracy of Mentz and the neighbouring towns formed an association similar to that of the Hanse Towns. It took the name of the Rhenish confederation, and acted with vigor, so that the castles of the banditti of the neighbourhood were burned, and several of their ruins are still seen. In the fourteenth century Mentz was a place of some literary and scientific note. It was taken by the Swedes in the thirty years' war, and in 1688 by the French. In 1792 it surrendered to the French; next year the Austrians bombarded it, and in a siege of three months a great part of the houses were burned down. In 1797 it again came into possession of the French, and by the peace of Luneville (February 1801), was formally ceded to them. In 1802 the archbishopric was suppressed; but at the final settlement of Europe it was given to Hesse. It is thirty-seven miles south-east of Coblentz, and ninety-nine north by east of Strasburg.

MENTZEL (Christian), a native of Furstenwald, in Brandenburg, celebrated for his skill in medicine and botany, in pursuit of which he travelled through many countries. He died, A.D. 1701, about the seventy-ninth year of his age. He was a member of the academy des Curieux de la Nature. His works are, 1. Index Nominum Plantarum, printed at Berlin, in folio, 1696; and reprinted with additions in 1715, under the title of Lexicon Plantarum Polyglotton Universale. 2. A Chronology of China, in German; Berlin, 1696, in 4to. The following MSS. of his composition are preserved in the royal library at Berlin. 1. Sur l' Histoire Naturelle du Brasil, 4 vols. folio. 2. Sur les Fleurs et les Plantes du Japon, with colored drawings, 2 vols. folio.

MENUF, or MENOUF, a city of Lower Egypt, the capital of the district Menufyeh. It is situated on the side of a canal, which has ceased to be navigable; and at three leagues from the town a strong dyke has been made across it, for the purpose of preventing the too copious influx of water. Twenty-two miles N.N.W. of Cairo.

MENU, the name of a celebrated code of Hindoo laws, called after one of the fourteen mystical personages of that name. It is also called *Manava Dherma Sastra*, and is attributed to the first Menu, or Swayambhoura.

MENUTHIAS, or MENUTHIASDE, in ancient geography, an island adjoining to the north-east of the promontory Prasum of Ethiopia, beyond Egypt. Some take it to be Madagascar, or the island St. Laurence. Isaac Vossius will have it to be Zanzibar, Madagascar being at a greater distance from the continent than the ancients ever sailed to, whereas Menuthias was nearer; yet, though Zanzibar be nearer the continent, it is nearer the equator than Ptolemy's Menuthias, placed in lat. 12° 30′ S.

MENYANTHES, marsh trefoil, or buckbean, a genus of the monogynia order, and pentandria class of plants; natural order twenty-first, preciæ: COR. hairy; stigma bifid: CAPS. unilocular. This plant grows wild in moist marshy places in many parts of Britain. It has three oval leaves standing together upon one pedicle, which issues from the root; their taste is very bitter, and somewhat nauseous. Mr. Lightfoot says, the flowers are so extremely beautiful, that nothing but the requisite marshy soil could exclude it from a place in every garden. They grow in an elegant spike; are white, dashed with pink, and fringed internally with hairs. The Highlanders esteem an infusion of the leaves a good stomachic. Dr. Withering prescribes it in rheumatisms and dropsies; a drachm of them in powder destroys worms. In a scarcity of hops, this plant is used as a substitute in the north of Europe. The powdered roots are sometimes used in Lapland instead of bread, but they are unpalatable. From the Upsal Experiments it appears that, though goats eat it, sheep often will not. Cows, horses, and swine, refuse it.—Dr. Lewis recommends it, as an efficacious aperient, deobstruent, and gentle laxative. It has great reputation in scurvy and scrofula. Inveterate cutaneous diseases have been removed by an infusion of the leaves, drunk to the quantity of a pint a day, at proper intervals, and continued for some weeks. Boerhaave relates, that he was relieved of the gout by the juice mixed with whey.

MANZALEH, a large lake of Lower Egypt, extending eastward along the coast from the Damietta branch of the Nile. The French general Andreossy thinks it occupies the space formerly traversed by the Tanitic, Mendesian, and Pelusiac branches of the Nile, and has been formed out of them. It is about sixty miles in length, and twenty-five in extreme breadth, being

divided by a peninsula into two large gulfs, and the whole separated from the sea by a long and narrow tongue of land. The general depth is about five fathoms, but in some parts it is double, and even much greater. The water, which is phosphoric, is less salt than that of the sea; and in some places, during the inundation, may even be drunk. The lake abounds in fish, and in the entrance porpoises are found. It communicates with the sea only by two practicable mouths, those of Dybey and Omm Faredge, supposed to be the ancient Mendesian, and Tanitic mouth of the Nile. There is a considerable number of uninhabited islands on it. Some of them are covered with ruins however. The fishermen on the lake, and the Bedouins who inhabit the surrounding villages, are remarkably barbarous and ignorant.

MENZIKOFF (Alexander), a Russian prince, originally an apprentice to a pastry-cook near the palace of Moscow. By a fortunate circumstance he was, in early life, placed in the household of Peter the Great. Having made himself master of several languages, he first rendered himself agreeable, and afterwards became necessary to his master. He assisted Peter in all his projects; and was rewarded with the government of Ingria, the rank of prince, and the title of major-general. He signalised himself in Poland in 1708 and 1709; but in 1713 he was accused of embezzling the public money, and fined 300,000 crowns. The czar remitted the fine, and, having restored him to favor, gave him the command of an army in the Ukraine in 1719, and sent him as his ambassador into Poland in 1722. Constantly employed in endeavouring to preserve his influence after the death of his master, who was then evidently on the decline, Menzikoff discovered the person to whom the czar intended to leave the succession. The emperor was highly offended, and his penetration cost him the principality of Plescoff; and, on the death of the czar, in 1725, he was active in bringing different parties in Russia to agree to the succession of Catharine, under whom he enjoyed continued favor. This princess was not ungrateful. In appointing her son-in-law Peter II. to be her successor, she commanded him to marry the daughter of Menzikoff, and gave the czar's sister to his son. The parties were actually betrothed, and Menzikoff was made duke of Cozel and grand steward to the czar. But this summit of elevation was the prelude to his fall. The Dolgoroukis, favorites of the czar, had the influence to procure his banishment, together with that of his family, to one of his own estates, at the distance of 250 leagues from Moscow. But, having the imprudence to leave the capital with great parade, a party of soldiers was sent after him, who reduced him to the rank and dress of a peasant, and carried him and his family in waggons to Siberia; where, after losing his wife on the journey, and one of his daughters, he died November 2, 1729. His surviving son and daughter, after seeing their persecutor Dolgorouki degraded and banished to the same inhospitable climate, were recalled to Moscow by the empress Ann; and left Dolgorouki in possession of their cottage. Young Menzikoff was made captain of the guards, and received the fifth part of his father's possessions.

MENZINI (Benedict), a celebrated Italian poet, born in Florence. He was professor of eloquence at the college of Sapienza at Rome, where he died in 1704. He wrote, 1. The Art of Poetry. 2. Satires, Elegies, Hymns, and the Lamentations of Jeremiah. 3. Academia Tusculana, a work in verse and prose, which is his masterpiece.

MEPHITIC, or MEPHITICAL, a word applied to any kind of noxious vapor; but generally to that species of gas called carbonic acid gas. See CHEMISTRY.

MEPHIT'ICAL, *adj.* Lat. *mephitis.* Ill-savored; stinking.

Mephitical exhalations are poisonous or noxious steams issuing out of the earth, from what cause soever.

MEPHITIS, the name of the goddess who presided over the pestilential vapors, and was worshipped in ancient Italy, particularly at Cremona, and by the Hirpini. See AMPSANCTI.

MEQUINEZ, a city of Morocco, the frequent residence of the emperors, is situated in a fine plain, watered by numerous rivulets, and surrounded with a wall six feet high. Muley Ismael resolved to make it the capital of his northern dominions, considerably enlarged the city, and erected a beautiful palace. The Brebers of the mountains often make incursions even to its gates. The seraglio occupies an immense quadrangular space, being built only upon the ground floor; the rooms are long and narrow, and the light is communicated only by folding doors. About 100 years ago a convent was founded here by the kings of Spain. Long. 5° 50′ W., lat. 33° 56′ N.

MER'CABLE, *adj.*
MER'CANTANT, *n. s.*
MER'CANTILE, *adj.*
MER'CAT, *n. s.*
MER'CATURE.

Lat. *mercor, merx, mercatus, mercatura.* To be bought or sold: mercantant seems used in a cant way by Shakspeare, after the Ital. *mercatante*, to signify a foreign merchant or trader: mercantile is commercial; relating to trade or commerce: mercat, an obsolete name for a market, or place of resort for trade: mercature, which we only find in Dr. Johnson, the practice of buying and selling.

MERCANTILE SYSTEM, in political economy is one that prevails to a greater or less extent in every country of Europe. It was introduced in France by Colbert. (q. v.) As originally understood and acted upon, it embraces some fallacious doctrines, and carries some just ones to excess. The notion, for example, that wealth is derived mostly from foreign commerce, and depends upon an annual importation of specie, called the balance of trade, is erroneous. This balance was understood to be the bullion or coin received by a country in exchange for a part of its exports, and the foreign trade was supposed to be advantageous and promotive of the national wealth in proportion as the returns of trade were made in the precious metals, instead of other merchandise, whereas an exchange for iron, tin, leather, or any other useful merchantable commodity, is quite as advantageous

as the importation of specie. It will depend upon the wants of the community whether the importation of one or another article will most promote the national wealth. It would be quite absurd, therefore, to attempt, by legislation, to force trade to yield a balance in specie. As far as this was a direct object of the commercial system, it was accordingly mistaken. If a nation needs other things more than specie, such prices will be offered as will induce their importation. But this notion of the importance of the balance of exports and imports is not without its truth in a certain respect. It is undoubtedly an evil for one nation to be constantly indebted to another. It will be found true between individuals, different districts of the same country, and also between different nations, that the indebted party is the one most liable to make sacrifices. If a people or district, or an individual, will keep in advance of their means, and anticipate the income of the coming year, the consequence will be a perpetually straitened and embarrassed state. This was always the case with the British American colonies, and even of the states for many years after the establishment of the American independence. The liberal credits in England enabled them to anticipate their income, and they were accordingly always largely indebted to England, and thus constantly straitened and distressed, notwithstanding the country was, during the same time, rapidly growing in population and wealth. It is desirable that the commerce of a country should be so conducted as not to keep the country constantly indebted. If we were, therefore, to consider the balance of trade to be a constant standing balance of debt due to, or from, a country, in this sense it would be a subject of great importance. The consequence of large foreign credits, and of the desire to consume more of foreign products than the people have present produce of their labor sufficient to pay for, is occasionally to drive specie from the country; and the more extensive the credits, the more complete and exhausting will be this drain when it happens. The only way of preventing its recurrence is to produce at home so great a proportion of the commodities wanted for consumption, that the exportable produce will be amply sufficient to pay, in the foreign markets, for the foreign products needed. But, whether legislation shall be at all, and if at all, to what extent, directed to the advancement of commerce, or any other branch of industry, so as incidentally and consequentially to affect the kind and amount of exchanges with foreign nations, are much agitated questions. The practice of the whole civilized world is to legislate with a reference to national industry, and such it always has been. The real ground of doubt seems to relate to the proper objects and extent of this legislation.

MERCARA, a town and fortress of the Mysore, Hindostan, and district of Coorg, of which it is the capital. It was built by Hyder Aly in 1773, after he had conquered the country, and taken prisoner the rajah. It was again besieged by the Coorgs in 1785, but without avail. By the treaty with Tippoo, in 1792, he was, however, compelled to relinquish Coorg in favor of the old family, which, since that period, has resided here.

MERCATOR (Gerard), one of the most celebrated geographers of his time, was born at Ruremonde in 1512. He applied himself with great industry to geography and mathematics. The emperor Charles V. had a particular esteem for him, and the duke of Juliers made him his cosmographer. He composed a chronology, some geographical tables, an atlas, &c., engraving and coloring the maps himself. He died in 1594. His method of laying down charts is still used. See MAPS.

MERCATOR (Nicholas), F. R. S., an eminent mathematician in the seventeenth century, born at Holstein. He came to England about 1660, where he lived many years. He endeavoured to reduce astrology to rational principles. He published several works, particularly Cosmographia. He gave the quadrature of the hyperbole by an infinite series; which was the first appearance in the learned world of a series of this sort drawn from the particular nature of the curve.

MERCATORUM FESTUM, a festival kept by the Roman merchants on the 15th of May in honor of Mercury, who presided over merchandise. A sow was sacrificed on the occasion, and the people present sprinkled themselves with water from the fountain called aqua Mercurii; the whole concluding with prayers to the god for the prosperity of trade.

MER'CENARY, *adj.&n.s.* } Fr. *mercenaire;*
MER'CENARINESS, *n. s.* } Lat. *mercenarius.*
Hired or bribed; corrupted by money; venal: a hireling: mercenariness is venality; undue respect to hire or pecuniary reward.

> He a poor *mercenary* serves for bread;
> For all his travel, only clothed and fed.
>
> *Sandys.*

MER'CER, *n. s.* } Fr. *mercier;* Ital. *mer-*
MER'CERY. } *ciaro;* of Lat. *merx, mercis,*
merchandise. A dealer in silks (as a superior kind of merchandise): mercery, the trade in silks.

> The draper and *mercer* may measure religion as they please, and the weaver cast her upon what loom he please.
>
> *Howel.*

> The *mercery* is gone from out of Lombard-street and Cheapside into Paternoster-row and Fleet-street
>
> *Graunt.*

MER'CHAND, *v. a.* } Fr. *marchand*
MER'CHANDISE, *n. s.* & *v. n.* } *marchandise.* It
MER'CHANT, *n. s.* } *mercanter, mer-*
MER'CHANTABLE, *adj.* } *cadentia;* Span.
MER'CHANTMAN, *n. s.* } *mercadina;* Port.
mercadoria; all of Lat. *merx, mercator.* To traffic; transact in trade; exercise commerce; this is the sense of both the verbs, which are however seldom used: merchandise, as a substantive, is traffic; commerce; wares bought or sold: a merchant, he who exercises that traffic; and sometimes a wholesale as distinct from a retail dealer: merchantable, marketable; in condition to be bought or sold: merchantman, a trading ship.

MERCHET, or MERCHETUM. See MARCHET. Anciently no baron, or military tenant, could marry his sole daughter and heir, without such

leave purchased from the king, pro maritanda filia. And many servile tenants could neither send their sons to school, nor give their daughters in marriage, without express leave from the superior lord.

MERCIA, one of the seven kingdoms founded in England by the Saxons. Though the latest formed, it was the largest of them all, and grew by degrees to be the most powerful. On the north it was bounded by the Humber and the Mersey, which separated it from Northumberland; and on the east by the sea, and the territories of the East Angles and Saxons; on the south by the Thames; and on the west by the Severn and Dee. It comprehended about seventeen modern counties, being equal in size to the province of Languedoc, very little less than the kingdom of Arragon, and superior in size to that of Bohemia. Penda was its first monarch; and the name is derived from the Saxon word merc, i. e. a march, bound, or limit, because the other kingdoms bordered upon it on every side; and not from the river Mersey, as some allege. Penda assumed the regal title A. D. 626, and was of the age of fifty at the time of his accession; after which he reigned nearly thirty years. He was of a most turbulent temper, differing occasionally with almost all his neighbours, calling in the Britons to his assistance, and shedding more Saxon blood than had been spilt in all their intestine quarrels. He slew two kings of Northumberland, three of the East Angles, and compelled Kenwall, king of the West Saxons, to quit his dominions. He was at length slain, with most of the princes of his family, and a multitude of his subjects, in a battle fought near Leeds by Osway king of Northumberland, A. D. 655. He had the year before killed Anna king of the East Angles in battle, whose brother Ethelred notwithstanding took part with Penda. On the other hand, Penda the eldest son of Penda, to whom his father had given the ancient kingdom of the Mid Angles, had two years before married the natural daughter of king Osway, and had been baptised at his court. But, after Penda had conquered the East Angles, he resolved to turn his arms against Northumberland. Osway, to prevent this rupture, offered large sums, and jewels of great value, to purchase peace; these offers being rejected, he was reduced to the necessity of deciding the quarrel by the sword. The river near which the battle was fought overflowing, there were more drowned than killed. Amongst these, as the Saxon Chronicle informs us, there were thirty princes of the royal line, some of whom bore the title of kings; and also Ethelred king of the East Angles, who fought on the side of Penda, against his family and country. His son Penda, who had married Osway's daughter, became a Christian, and was not long after murdered by the malice of his mother. His brother Wolfher becoming king, embraced the Christian faith, and proved a very victorious and potent monarch; and is commonly styled king of the Anglo-Saxons, as also are seven of his immediate successors, though none of them are known by that title in the Saxon Chronicle. The extent of the Mercian territories was so ample as to admit, and so situated as to require, subordinate rulers in several provinces; who, if they were of the royal line, had the title of king; which occasions some confusion in their history. Besides establishing episcopal sees and convents, the Saxon monarchs improved and adorned their dominions otherwise, and Mercia was greatly improved. Coventry, being situated in the centre, was usually the royal residence. Penda, who was almost continually in a state of war, lived, as his military operations directed, in some great town on the frontiers. Wolfher built a castle or fortified palace for his own residence, which bore his name. Offa kept his court at Sutton Walls, near Hereford. In each of the provinces there resided a chief magistrate; who, if of the royal blood, had the title of king. Penda, when he married Osway's daughter, had the title of king of Leicester. Ethelred made his brother Merowald king of Hereford; who, dying without issue, bequeathed it to his younger brother Mercelm. The like honors were sometimes conferred upon the princesses; and hence we occasionally read of vice-queens. By these means the laws were better executed, the obedience of the subjects more effectually secured, and the splendor of these residences constantly kept up and augmented. At length, the crown devolving sometimes on minors, and sometimes on weak princes, intestine factions also prevailing, the strength of this hitherto mighty kingdom began to decline. Egbert, the most prudent and most potent monarch of th West Saxons, took advantage of these circumstances; and, having encouraged the East Angles to attempt the recovery of their independence, he attacked the Mercians, and after a short war obliged them to submit. But this was not an absolute conquest, the kings of Mercia being allowed by him and his successors to retain their titles and dominions, till the invasion of the Danes put an end to their rule; and, when the Danes were afterwards expelled by the West Saxons, it sunk into a province, or rather was divided into many.

MERCURIALIS (Jerom), an eminent Italian physician, born at Forli in 1530, where he first practised; but was afterwards professor of medicine successively at Padua, Bologna, and Pisa. His writings on physic are very numerous; besides giving an edition of Hippocrates in Greek and Latin, with notes. He died in 1606; and in 1644 some select pieces of his were published at Venice in one volume folio.

Mercurialis, mercury, in botany, a genus of the enneandria order, and diœcia class of plants. natural order thirty-eighth, tricoccæ. Male cal. tripartite: cor. none; but nine or twelve stamina; the anthera globular and twin. Female cal. tripartite: cor. none, but two styles: caps. bicoccous, bilocular, and monospermous. There are several species:

1. M. annua, or French mercury, with spiked flowers, male and female. This is an annual plant, with a branching stalk about a foot high, garnished with spear-shaped leaves of a pale or yellowish-green color. The male plants have spikes of herbaceous flowers growing on the top of the stalks: these fall off soon; but the female plants, which have testiculated flowers

proceeding from the side of the stalks, are succeeded by seeds, which, if permitted to scatter, will produce plenty of plants of both sexes.

2. M. perennis, mountain, or dog's mercury, with spiked or testiculated flowers, grows under hedges and in woods in many parts of Britain. It has a perennial root, which creeps in the ground; the stalks are single, and without branches, rising ten or twelve inches high, garnished with rough leaves, placed by pairs at each joint, of a dark green color, indented on their edges; these have their male flowers growing in spikes, upon different plants from those which produce seeds. This species is of a soporific deleterious nature, noxious both to man and beast. Some have eaten it by mistake instead of English mercury, and have thereby slept their last. In the isle of Skye it is called lusglen bracadale; and an infusion of it is sometimes taken to bring on a salivation.

3. M. tomentosa, or shrubby hairy mercury, is a native of the South of France, Spain, and Italy. It has a shrubby branching stalk, growing a foot and a half high, garnished with oval leaves placed by pairs, and covered with a white down on both sides. The male flowers grow in short spikes from the side of the stalks upon different plants from the first. All the species are easily propagated by seeds.

MER'CURY, *n. s.* Lat. *mercurialis*. A plant.

Herb *mercury* is of an emollient nature, and is eaten in the manner of spinach, which, when cultivated in a garden, it greatly excels. *Hill.*

MER'CURY, *n. s.* } Lat. *Mercurius, mer-*
MERCURIFICA'TION, } *curialis*; from the nim-
MERCU'RIAL, *adj.* } ble deity of this name.
Quicksilver, see below: also, metaphorically, agility; sprightly qualities: mercurification, the act of mixing any thing with mercury: mercurial, formed of mercury; under the influence or operation of mercury; active; sprightly.

I know the shape of 's leg: this is his hand,
His foot *mercurial*, his martial thigh,
The brawns of Hercules. *Shakspeare. Cymbeline.*

This youth was such a *mercurial*, as could make his own part, if at any time he chanced to be out. *Bacon's Henry VII.*

I add the ways of *mercurification*. *Boyle.*

The gall of animals and *mercury* kill worms; and the water in which *mercury* is boiled has this effect. *Arbuthnot.*

Thus the *mercury* of man is fixed,
Strong grows the virtue with his nature mixed;
The dross cements what else were too refined,
And in one interest body acts with mind. *Pope.*

Tully considered the dispositions of a sincere, more ignorant, and less *mercurial* nation, by dwelling on the pathetick part. *Swift.*

MERCURY, or quicksilver, in chemistry, may be distinguished from all other metals by its extreme fusibility. It does not take the solid state until cooled to the thirty-ninth degree below zero of Fahrenheit, and is of course therefore always fluid in the temperate climates of the earth. Its color is white and rather bluer than silver: its specific gravity 13·6. When solid it is malleable; but, at the common temperature of our earth, volatile and evaporating in a slight degree. At a heat of about 656° it boils rapidly, and rises in dense copious fumes. The following is a list of its principal ores, as arranged by Jamieson.

Species I. *Native mercury.*

1. *Fluid mercury.* It occurs principally in rocks of the coal formation, associated with cinnabar, corneous mercury, &c. Small veins of it are rarely met with in primitive rocks, accompanied with native silver, &c. It is found at Idria in the Friaul; Niderslana in Upper Hungary; in the Palatinate; Deux Ponts, &c.

2. *Dodecahedral mercury, or native amalgam,* divided into, *a, fluid or semi-fluid amalgam.* Color tin-white. In roundish portions; and crystallised in a rhomboidal dodecahedron, rarely perfect. Splendent. When cut it emits a creaking sound. As hard as talc. Specific gravity 10·5. Its constituents are, mercury 74, silver 25. It is found at Deux Ponts; and *β, solid amalgam.* Color silver-white. Massive and disseminated. Fracture flat conchoidal. As hard as gypsum. Brittle. Creaks strongly when cut. Specific gravity 10·5. The mercury flies off before the blow-pipe. Its constituents are, mercury 74, silver 25.—Heyer. Mercury 64, silver, 36.—Klaproth. It is found in Hungary, the Deux Ponts, &c.

Species II. *Cinnabar,* or *prismato-rhomboidal ruby-blende.*

1. *Dark red cinnabar.* Color cochineal-red. Massive, disseminated, imitative, and crystallised. Primitive form a rhomboid. Secondary forms, a regular six-sided prism, an acute rhomboid, and a six-sided table. Splendent, adamantine. Translucent. Streak scarlet-red, shining. Harder than gypsum. Sectile and easily frangible. Specific gravity 6·7 to 8·2. It melts, and is volatilised with a blue flame and sulphureous odor. Its constituents are, mercury 85·5, sulphur 14·75. —Klaproth.

2. *Bright red cinnabar.*—Color bright scarlet red. Massive, and in delicate fibrous concretions. Glimmering and pearly. Fracture earthy. Opaque. Streak shining. Soils. Friable. It occurs in rocks of clay-slate, talc-slate, and chlorite-slate; in veins at Horzowitz in Bohemia; at Idria, &c.

3. *Hepatic cinnabar,* divided into, *a, compact.* Color between cochineal-red and dark lead-gray. Massive. Glimmering and semi-metallic. Streak shining. Opaque. Soft. Sectile. Specific gravity 7·2. Its constituents are, mercury 81·8 sulphur 13·75, carbon 2·3, silica 0·65, alumina 0·55, oxide of iron 0·2, copper 0·02, water 0·73 *β, slaty mercurial hepatic ore.* Color as above, but sometimes approaching to black. Massive, and in roundish concretions. Lustre shining, semi-metallic. Fracture curved slaty. Most easily frangible. Streak cochineal-red, inclining to brown. Rather lighter than the compact. It occurs in considerable masses in slate-clay and bituminous shale. It is most abundant in Idria.

Species III. *Corneous mercury,* or *horn quicksilver.*

Pyramidal corneous mercury. Color ash-gray. Vesicular, with interior crystallisations, which are, a rectangular four-sided prism, variously acuminated, and a double four-sided pyramid. Crystals very minute. Shining, adamantine. Cleavage single. Faintly translucent. Soft.

Sectile and easily frangible. It is totally volatilised before the blow-pipe, with a garlic smell. It is soluble in water, and the solution mixed with lime water gives an orange-colored precipitate. Its constituents are, oxide of mercury 76, muriatic acid 16·4, sulphuric acid 7·6.—Klaproth. It occurs in Bohemia, &c.

Mercury is not perceptibly altered by mere exposure to the air; though by long agitation, with access of air, it becomes converted into a black powder or oxide, which gives out oxygen by heat, the metal being at the same time revived.

When calomel or protochloride of mercury is acted on by potash-water, it yields the pure black protoxide; and, when corrosive sublimate or the deutochloride is treated in the same way, it affords the red deutoxide. The former oxide, heated with access of air, slowly changes into the latter. The constituents of the first are 100 metal + 4 oxygen; of the second 100 + 8. Hence the prime equivalent of mercury is 25. At a red heat both oxides emit their oxygen, and pass to the metallic state. A moderate heat converts the black oxide partly into running mercury and partly into red oxide. The deutoxide, as usually prepared from the nitrate by gentle calcination, is in brilliant red scales, which become of an orange hue when finely comminuted. It frequently contains a little undecomposed subnitrate.

By triturating mercury with unctuous or viscid matters it is changed partly into protoxide, and partly into very minute globules. By exposing mercurial ointment to a moderate heat, the globules fall down, while a proportion of the oxide remains combined with the grease. This light gray chemical compound is supposed to possess all the virtues of the dark-colored ointment, and to be cheaper and more convenient in the application.

Red oxide of mercury is acrid and poisonous, and carries these qualities into its saline combinations. The protoxide is relatively bland, and is the basis of all the mild mercurial medicines.

1. When mercury is heated in chlorine it burns with a pale red flame, and the substance called corrosive sublimate is formed. This deutochloride may also be formed by mixing together equal parts of dry bideuto-sulphate of mercury and common salt, and subliming. The corrosive sublimate rises, and incrusts the top of the vessel, in the form of a beautiful white semi-transparent mass, composed of very small prismatic needles. It may be obtained in cubes, and rhomboidal prisms, or quadrangular prisms, with their sides alternately narrower, and terminated by dihedral summits. Its specific gravity is 5·14. Its taste is acrid, stypto-metallic, and eminently disagreeable. It is a deadly poison. Twenty parts of cold water dissolve it, and less than one of boiling water: 100 parts of alcohol at the boiling temperature dissolve 88 of corrosive sublimate; and at 70° they dissolve 37·5 parts. The constituents of this chloride are,—

Mercury,	25 . . .	73·53
Chlorine,	9 . . .	26·47

It may be recognised by the following characters:—it volatilises in white fumes, which seem to tarnish a bright copper-plate, but really communicate a coating of metallic mercury, which appears glossy white on friction. When caustic potash is made to act on it, with heat, in a glass tube, a red color appears, which by gentle ignition vanishes, and metallic mercury is then found to line the upper part of the tube in minute globules. Solution of corrosive sublimate reddens litmus paper, but changes syrup of violets to green. Bicarbonate of potash throws down from it a deep brick-red precipitate, from which metallic mercury may be procured by heating it in a tube. Caustic potash gives a yellow precipitate; but, if the solution be very dilute, a white cloud only is occasioned, which becomes yellowish-red on subsidence. Lime water causes a deep yellow, verging on red. Water of ammonia forms a white precipitate, which becomes yellow on being heated. With sulphureted hydrogen and hydrosulphurets, a black, or blackish-brown, precipitate appears. Nitrate of silver throws down the curdy precipitate characteristic of muriatic acid; and the protomuriate of tin gives a white precipitate. The proper antidote to the poison of corrosive sublimate is the white of egg, or albumen, which converts it into calomel. Sulphureted hydrogen water may also be employed, along with emetics. From six to twelve grains were the mortal doses employed by Orfila in his experiments on dogs. They died in horrible convulsions, generally in two hours. But when, with the larger quantity, the whites of eight eggs were thrown into the stomach, the animals soon recovered, after vomiting. Corrosive sublimate, digested with albumen for some time, was given in considerable doses with impunity.

2. Protochloride of mercury, mercurius dulcis, or calomel, is usually formed from the deutochloride, by triturating four parts of the latter with three of quicksilver, till the globules disappear, and subjecting the mixture to a subliming heat. By levigating and edulcorating with warm water the sublimed grayish-white cake, the portion of soluble corrosive sublimate which had escaped decomposition is removed. It may also be made by adding solution of protonitrate of mercury to solution of common salt. The protochloride or calomel precipitates. The following is the process used at Apothecaries' Hall, London:—50 lbs. of mercury are boiled with 70 lbs. of sulphuric acid, to dryness, in a cast iron vessel; 62 lbs. of the dry salt are triturated with 40½ lbs. of mercury, until the globules disappear, and 34 lbs. of common salt are then added. This mixture is submitted to heat in earthen vessels, and from 95 to 100 lbs. of calomel are the result. It is washed in large quantities of distilled water, after having been ground to a fine and impalpable powder.

When protochloride of mercury is very slowly sublimed, four-sided prisms, terminated by pyramids, are obtained. It is nearly tasteless and insoluble, and is purgative in doses of five or six grains. Its specific gravity is 7·176. Exposure to air darkens its surface. When two pieces are rubbed in the dark they phosphoresce. It is not so volatile as the deutochloride. Nitric acid dissolves calomel, converting it into corro-

sive sublimate. Protochloride of mercury is composed of

Mercury,	25·	84·746
Chlorine,	4·5	15·254

We have also two sulphurets of mercury; the black or ethiops mineral, and the red or cinnabar.

MERCURY, MERCURIUS, in the heathen mythology. Most of the actions and inventions of the Egyptian Hermes have been ascribed to the Grecian Mercury, the son of Jupiter, and Maia the daughter of Atlas. No one of all the heathen divinities had so many functions allotted to him as this god: he had constant employment both day and night, having been the common minister and messenger of all Olympus; particularly of his father Jupiter, whom he served with indefatigable labor, and sometimes indeed in a capacity of no very honorable kind. Lucian is very pleasant upon the multitude of his avocations; and, according to the emperor Julian, Mercury was no hero, but rather one who inspired mankind with wit, learning, and the ornamental arts of life, than with courage. He was also the patron of trade, and even of fraud and theft. Amphion is said, by Pausanias, to have been the first that erected an altar to this god; who, in return, invested him with such extraordinary powers of music (and masonry), as to enable him to fortify the city of Thebes, by the mere sound of his lyre. See AMPHION. Horace gives us the best account of his character, in his tenth Ode, lib. 1, which contains the substance of a long hymn to Mercury, attributed to Homer. His most magnificent temple was on mount Cylene, in Arcadia. He is described by the poets as a fair beardless youth, with flaxen hair, lively blue eyes, and a smiling countenance. He has wings fixed to his cap and sandals, and holds the caduceus in his hand (see CADUCEUS); and is frequently represented with a purse to show that he was the god of gain. The animals sacred to him were the dog, the goat, and the cock. In all the sacrifices offered to him, the tongues of the victims were burnt; and those who escaped imminent danger sacrificed to him a calf, with milk and honey.

MERCURY, ☿, in astronomy. See ASTRONOMY. This planet is brightest between his elongations and superior conjunction, very near to which last he can generally be seen. He becomes invisible soon after he has found his elongation, going towards his inferior conjunction; and becomes visible again a few days before his next elongation. The brightness of this planet alters sometimes very considerably in twenty-four hours. It has been observed when less than three degrees distant from the sun, and may, perhaps, sometimes be seen even in conjunction with it. Mercury and Venus appear brightest and most beautiful in the opposite parts of their orbits; the first between his elongations and superior conjunction, and the other between her elongation and inferior conjunction. Therefore Venus is seen in great perfection as a crescent, particularly in her inferior conjunction, whilst mercury is seldom seen in such perfect phases. Mercury should be always observed on or near the meridian. When farthest from the sun, he always appears with a very faint light; and when he has a great south declination, or the atmosphere is not perfectly clear, he seldom can be seen in those parts of his orbit where he only begins to recover his brightness, or where it is much diminished. He has frequently been seen on the meridian, even with a small telescope and small power.

MERCURY, in heraldry, a term used in blazoning by planets, for the purple color used in the arms of sovereign princes.

MERCURY BAY, a convenient bay on the north-east coast of the northernmost island of New Zealand, thus named by captain Cook, who observed here the transit of Mercury over the sun in 1769. It has abundance of wood and water; and in one of its rivers is an immense quantity of oysters. Long. 184° 4′ W., lat. 36° 48′ S.

MER'CY, *n. s.*
MER'CIABLE, *adj.*
MER'CIFUL, *adj.*
MER'CIFULLY, *adv.*
MER'CIFULNESS, *n. s.*
MER'CILESS, *adj.*
MER'CILESSLY, *adv.*
MER'CY-SEAT, *n. s.*

Fr. *merci*; Ital. *merce*, *misericordia*; Span. and Port. *misericordia*, of Lat. *misericordia*. Compassion; tenderness; clemency; unwillingness to punish; pardon; and, as mercy is supposed to be free, discretion; power to act, or refrain from acting, at pleasure: merciable is used by Spenser for merciful, which signifies compassionate; disposed to spare or pardon; or to kind services; the adverb and noun following, corresponding: merciless, without mercy; pitiless; severe; hard-hearted: mercilessly, in a ruthless or hard-hearted manner: mercy-seat, a peculiar part of the Jewish ark, and a name of our Lord Jesus Christ in the New Testament. See the following article.

Therfore be ye *merciful* as youre fadir is merciful. *Wiclif. Luk.* vi.

Make a *mercy-seat* of pure gold. *Exod.* xxv. 17.

Be *merciful*, O Lord, unto thy people thou hast redeemed. *Deut.* xxi. 8.

He shall have judgment without *mercy* that hath shewed no *mercy*. *St. James.*

The hand that ought to knit all these excellencies together is a kind *mercifulness* to such a one, as is in his soul devoted to such perfections. *Sidney.*

His mother *merciless*,
Most *merciless* of women Wyden hight,
Her other son fast sleeping did oppress,
And with most cruel hand him murdered pitiless. *Spenser.*

Nought but well mought him betight:
He is so meek, wise, *merciable*,
And with his word his work is convenable. *Id.*

'Twere a paper lost,
As offered *mercy* is. *Shakspeare. Cymbeline.*

The foe is *merciless*, and will not pity. *Shakspeare.*

Mercy is not strained;
It droppeth, as the gentle rain from heaven,
Upon the place beneath. It is twice blessed;
It blesseth him that gives and him that takes. *Id.*

Condition!
What good condition can a treaty find
I' the part that is at *mercy*? *Id. Coriolanus.*

Examples of justice must be made for terror to some; examples of *mercy* for comfort to others: the one procures fear, and the other love. *Bacon.*

Think not their rage so desperate to essay
An element more *merciless* than they. *Denham.*

Miserable men commiserate not themselves; bowelless unto others, and *merciless* unto their own bowels.
Browne.

Observe
His providence, and on him sole depend,
Merciful over all his works; with good
Still overcoming evil. *Milton.*

Good heaven, whose darling attribute we find
Is boundless grace, and *mercy* to mankind,
Abhors the cruel. *Dryden.*

What god so mean,
So *merciless* a tyrant to obey! *Id. Juvenal.*

Make the true use of those afflictions which his hand, *mercifully* severe, hath been pleased to lay upon thee. *Atterbury.*

We adore his undeserved *mercy* towards us, that he made us the chief of the visible creation.
Bentley's Sermons.

Use the means ordinary and lawful, among which *mercifulness* and liberality is one, to which the promise of secular wealth is most frequently made.
Hammond.

The most authentick record of so ancient a family should lie at the *mercy* of every infant who flings a stone. *Pope.*

Whatever ravages a *merciless* distemper may commit, she shall have one man as much her admirer as ever. *Id.*

A lover is ever complaining of cruelty while any thing is denied him; and, when the lady ceases to be cruel, she is, from the next moment, at his *mercy*.
Swift.

The torrent *merciless* imbibes
Commissions, perquisites, and bribes. *Id.*

The *mercy-seat* was the covering of the ark of the covenant, in which the tables of the law were deposited: it was of gold, and at its two ends were fixed the two cherubims, of the same metal, which, with their wings extended forwards, seemed to form a throne for the majesty of God, who in scripture is represented as sitting between the cherubims, and the ark was his footstool: it was from hence that God gave his oracles to Moses, or to the high-priest that consulted him. *Calmet.*

Seeds of *merciless* disease
Lurk in all that we enjoy;
Some that waste us by degrees,
Some that suddenly destroy. *Cowper.*

The MERCY-SEAT, or Propitiatory, in the Jewish tabernacle and temple, was strictly, not the covering of the ark, but the basis of the throne or standing-place of the cherubim. The latter are said to be made 'of,' as well as 'in the ends of the mercy-seat.' Whether the ark or chest beneath had or had not a distinct lid or cover seems doubtful.

The LXX., render the term כפרת, Exod. xxv. 17, by *ἱλαστηριον επιθεμα*, a propitiatory lid or covering, but generally by *ἱλαστηριον* alone, a propitiatory, which St. Paul calls it, Heb. ix. 5, and which he uses as a name of Christ, Rom. iii. 25. Our common version calling him in the latter place the 'propitiation for our sins,' states a most important truth, but not the truth of the original, which means to say that, in the character and work of Jesus Christ, is a constant seat or throne of mercy at which guilty men should apply. See Parkhurst, Locke, and Whitby, on the place.

MERDIN, a city of Diarbekir, the ancient Marde, Asiatic Turkey, is situated near the summit of a lofty mountain, on which is a castle. The town is difficult of access, being ascended on the north side only by a narrow winding pathway, and on the south by a road of a mile and a half in length very steep. Notwithstanding its situation it is well supplied with water, and the houses are built of very fine hewn stone, but have grated iron windows. The population, 11,000, are Arminians, Jews, Turks, Arabs, and Curds; the first being the largest in number. The walls are kept in repair; and a few old pieces of cannon are mounted on the castle. It is forty-five miles south of Diarbekir.

MERE, *adj.* } Lat. *merus*; Gr. *μειρω*.
MERE'LY, *adv.* } Sole; pure; plain; very; that or this only: merely, simply; only; thus and in no other manner.

Which thing we ourselves would grant, if the use thereof had been *merely* and only mystical.
Hooker.

Scotland hath foisons to fill up your will
Of your *mere* own. *Shakspeare. Macbeth.*
These external manners of laments
Are *merely* shadows to the unseen grief,
That swells with silence in the tortured soul.
Shakspeare.

As for conflagrations and great droughts, they do not *merely* dispeople, but destroy. *Bacon.*

The *mere* Irish were not admitted to the benefit of the laws of England, until they had purchased charters of denization. *Davies on Ireland.*

It is below reasonable creatures to be conversant in such diversions as are *merely* innocent, and have nothing else to recommend them. *Addison.*

From *mere* success nothing can be concluded in favour of any nation upon whom it is bestowed.
Atterbury.

What if the head, the eye, or ear repined,
To serve *mere* engines to the ruling mind. *Pope.*

Prize not your life for other ends
Than *merely* to oblige your friends. *Swift.*

Let eastern tyrants from the light of heaven
Seclude their bosom slaves, meanly possessed
Of a *mere*, lifeless, violated form.
Thomson's Spring.

MERE, *n. s.* Sax. mepe. A pool, or lake or boundary. See MEER.

Meres stored both with fish and fowl.
Camden.

The mislayer of a *mere* stone is to blame: but it is the unjust judge that is the capital remover of land-marks, who defineth amiss of lands. *Bacon.*

MERE (George Brossin Chevalier de), a French writer of the seventeenth century. He published, 1. Discourses on Wit and Conversation; 2. The Elegancies of Discourse; 3. Treatises on Politeness, Eloquence, and Speech; 4. Letters, &c. He died at his seat, in Poitou, in 1690.

MERETRIC'IOUS, *adj.* } Lat. *meretricius*,
MERETRI'CIOUSLY, *adv.* } *meretrix*. Shewy; fallacious; alluring by false show; practised by prostitutes.

Our degenerate understandings have suffered a sad divorce from their dearest object, defile themselves with every *meretricious* semblance, that the variety of opinion presents them with.
Glanville's Scepsis.

Not by affected, *meretricious* arts,
But strict harmonious symmetry of parts.
Roscommon.

By happy alchemy of mind,
They turn to pleasure all they find:
They both disdain in outward mien
The grave and solemn garb of spleen,
And *meretricious* arts of dress
To feign a joy and hide distress. *Green.*

No *meretricious* graces to beguile,
No clustering ornaments to clog the pile.
Cowper.

MERETRIX, among the Romans, differed from the prostibula. The prostibulæ were common courtezans, with bills over their doors signifying their profession, and were ready at all times to receive persons; whereas the meretrices entertained none but at night. The meretrices differed in their dress from the matrons; the former wore the toga and short tunics, like those of the men; the latter wore the pulla and the stola of such a length as to reach to their feet.

MERGUI, a sea-port town of Lower Siam, in the Birman empire, was taken from the Siamese by the Birmans in 1759, and has remained in their possession ever since. It is situated favorably for commerce, about six miles up the Tannaserim River; middling sized vessels may go up to the town. The principal articles of export are ivory, tutenague, rice, and other provisions; French privateers during the war, used to anchor at King's Island, off the mouth of the river, and were there supplied by the boats of the natives. A number of Mahometans are settled at Mergui, and the native Christians are permitted to have a Roman Catholic priest and church. It is governed by an officer sent from Ava. The French formerly had a settlement here. Long. 98° 23′ E., lat. 12° 12′ N.

The MERGUI ARCHIPELAGO consists of islands extending 135 miles from north to south, along the coast of Tannaserim, and the isthmus of the Malay peninsula, with a strait between them and the mainland, of fifteen to thirty miles broad, having regular soundings and good anchorage. The islands are well wooded and edged with rocks, encrusted with small oysters. They are not inhabited, although the soil appears fertile. The principal are King's Island, St. Matthew's, Clara, and Tannaserim. They belong to the Birmans.

MERGUS, in ornithology, a genus of birds of the order of anseres, distinguished by having the beak of a cylindrical figure, hooked at the extremities, and its denticulations of a subulated form.

1. M. albellus, the smew, weighs about thirty-four ounces; the length eighteen inches, the breadth twenty-six; the bill is nearly two inches long, and of a lead color; the head is adorned with a long crest, white above and black beneath; the head, neck, and whole under part of the body, are of a pure white; the tail is of a deep ash-color; the legs a bluish-gray. The female, or lough diver, is less than the male; the back, the scapulars, and the tail, are dusky; the belly is white. The smew is seen in England only in winter, when it is sometimes met with at the southern parts of it; also in France, where it is called la piette; in Kent it is called the Magpie diver. On the continent it is found as far south as Carniola; it frequents also Iceland, where, or in some other arctic region, it passes the summer; and where it is supposed to breed, as it has been observed to migrate, in company with other mergansers, ducks, &c., in their course up the Wolga, in February. It also inhabits America.

1. M. cucullatus, or crested diver of Catesby, has a globular crest, white on each side; and the body is brown above and white below. This elegant species inhabits North America. It appears at Hudson's Bay about the end of May, and builds close to the lakes. The nest is composed of grass, lined with feathers from the breast; the number of eggs is from four to six. The young are yellow; are fit to fly in July, and all depart thence in autumn. They appear at New York, and other parts as low as Virginia and Carolina, in November, where they frequent fresh waters. They return to the north in March; and are called at Hudson's Bay Omiska sheep.

3. M. merganser, the goosander, weighs four pounds. Its length is two feet four inches; the breadth three feet four. The bill is three inches long, narrow, and finely toothed or serrated; the color of that and of the irides is red. The dun diver, or female, is less than the male: the head and upper part of the neck are ferruginous; the throat white; the feathers on the hind part are long, and form a pendant crest; the back, the coverts of the wings, and the tail, are of a deep ash color; the greater quill-feathers are black, the less white; the breast and middle of the belly are white, tinged with yellow. The goosander seems to prefer the more northern situations to those of the south, not being seen in the latter except in very severe seasons. It continues the whole year in the Orkneys; and has been shot in the Hebrides in summer. It is common on the continent of Europe and Asia, but most so towards the north. It is found also in Iceland and Greenland, and breeds there, retiring southward in winter, when it is found about the lake Baikel. It is common in America, inhabits New York in winter, and retires thence in April to Hudson's Bay.

4. M. minutus, the red-headed smew, weighs about fifteen ounces; the length one foot four inches, the breadth one foot eleven; the bill is of a lead color; the head slightly crested and of a rust color; the hind part of the neck is of a deep gray, the fore part clouded with a lighter color of the same kind; the back and tail are of a dusky ash color, the legs of a pale ash color. It is a native of Europe. Birds of this genus (Mr. Latham observes) are in general not so well flavored as those of the duck kind; yet we have often met with the last species in the London markets, and by some they are thought to be very little inferior to the wild duck; which last now and then partakes of the fishy haut gout, a flavor not disagreeable to the palates of connoisseurs.

5. M. serrator, the red-breasted merganser, weighs about two pounds; the length is one foot nine inches, the breadth two feet seven; the bill is three inches long; the lower mandible red; the upper dusky; the irides a purplish red; head and throat a fine changeable black and

green; on the former a long pendant crest of the same color; the tail short and brown; the legs orange-colored. The head and upper part of the female are of a deep rush-color, and the tail ash-colored. These birds are most common in the northern parts of Great Britain. They breed on Loch Mari, in Ross-shire, and in the Isle of Islay. The species is common in most parts of the north of Europe, on the continent, and as high as Iceland, where it is called vatus-ond; also in the Russian dominions, about the great rivers of Siberia, and the lake Baikal. They are numerous in Greenland in summer, where they breed on the shores. The eggs are like those of a wild duck, but smaller and whiter. They dive well, and are very active in the water; but the Greenlanders often kill them with darts, especially in August, being the time of moulting. They are frequent in Newfoundland, and often appear in Hudson's Bay in large flocks, but of a larger size than in Europe. They generally come in pairs in the beginning of June, as soon as the ice breaks up; make the nest soon after their arrival, chiefly on dry spots of ground in the islands, and lay from eight to thirteen white eggs, the size of those of a duck: the nests are made of withered grass, and lined with the down of the breast. The young are of a dirty brown, like young goslings. They all depart south in October to the lakes, where they may have open water.

MERIAN (Maria Sibylla), a celebrated paintress, born at Frankfort in 1647. She was the daughter of Matthias Merian, a noted engraver and geographer. As she showed a very early fondness for painting she was instructed by Abraham Mignon, from whom she learned great neatness and delicacy of color. Her genius particularly led her to paint reptiles, flowers, and insects, which she designed from nature with extraordinary exactness and truth. She even undertook a voyage to Surinam, to paint the insects and reptiles peculiar to that climate; and on her return published two volumes of engravings from her designs, which are well known to the curious. She died in 1717. Her daughter Dorothea Henrietta Graff, who painted in the same style, and had accompanied her mother to Surinam, published a third volume from the designs of Sibylla.

MERIDA, a town of Estremadura, Spain, situated on a rising ground, on the Guadiana, across which there is here a substantial bridge. This place was the Augusta Emerita of the Romans and Goths, having been peopled with soldiers of the fifth and tenth legions. It was one of the largest and most thriving towns of ancient Spain, but fell gradually to decay in the wars between the Goths and Moors, and has never recovered itself. Its antiquities, however, render it an object of interest, and comprise vestiges of superb temples, bridges, aqueducts, baths, a triumphal arch, circus, theatre, naumachia; together with the traces of two immense reservoirs at a distance from the town. Merida was the seat of a Gothic archbishop; and a council was held here in the middle of the seventh century. Besieged and taken by the Moors, in 713, it was for some time the capital of a small kingdom. The Spaniards retook it in 1230; the French in January 1811; the British under general (now lord) Hill, in June 1812. Its environs abound in corn, wine, and fruits. Population 4500. Thirty miles east of Badajoz and 108 north-west of Cordova.

MERIDA, a province of Colombia, is bounded on the north by Maracaibo, on the east by Venezuela, on the west by Santa Maria, and on the south by Santa Fé and Juan de los Llanos. Its great geographical feature is the amazing elevation of a branch from a chain of the Andes, which entirely pervades this province on its western side, rising beyond the lower period of perpetual snow, and to the height of 15,000 feet above the level of the sea.

The climate of this province is variable, on account of the vicinity of the snowy mountains, and the unequal heights of the land. The rainy season lasts from March to November, during which time the water descends in torrents; and rains are also frequent, but not so heavy, in the other months. When westerly winds prevail febrile diseases are common.

The Rio Apure, and other rivers of considerable size, rise or receive their tributary streams from the mountains of Merida, watering in their courses immense tracts of level and fertile land which extend from these mountains to the vicinity of the Orinoco. Little is known concerning the interior of this country; but it produces maize, beans, peas, potatoes, cassada, wheat of the finest quality, barley, rye, &c., as well as the tropical and European fruits, in great plenty. It also contains several plantations of sugar, cacao, and coffee. The cattle are in immense numbers.

MERIDA, the chief city of the above province, is situated in 8° 10′ N. lat., and 73° 45′ W long.; twenty-five leagues south-east of Varinas, eighty leagues south of Maracaibo, and 140 leagues south-east of Caraccas. It stands in a valley surrounded by three rivers and lofty mountains, three leagues long and three-quarters of a league in breadth. The climate is so variable that it often experiences every day the four seasons of the year.

The rains are heavy: they fall through the whole year, and with redoubled violence from the month of March to November; but at all times they leave some interval of dry weather.

None of the three rivers is navigable, on account of the rapidity of their currents, and the obstacles opposed to navigation by straits, sometimes formed by rocks and at others by mountains: its bed is so contracted as to create falls which no boat can pass. The reason for the inhabitants not having sought to overcome these difficulties is the excessive insalubrity of that part of the lake of Maracaibo into which the river Chama disembogues.

At a short distance from the capital a college and seminary for priests is established: in this seminary also the inhabitants are educated. There are also here a handsome cathedral and three convents, with several chapels.

In the college and seminary are professors of philosophy, theology, morality, the canon and the civil law. All the schools are under the im

mediate authority of a bishop, and have a rector and vice-rector. An open disposition, a sound understanding, and a love of literature, are remarked in the whites of Merida. No class disdains labor.

The inhabitants insist that neither the cold nor the heat is ever felt here to a degree that can inconvenience, and that throughout the year either silk or woollen clothes may be worn indifferently. They peculiarly dread, however, the west wind, as it never blows without leaving traces of its malignity, and the weather is very changeable.

At some distance are plantations of sugar, cacao, and coffee, the quality of which is very superior. All the environs of Merida are covered with fruits, pulse, such as maize, beans, peas of every sort, potatoes, cassada, wheat of the finest quality, barley, &c. These are consumed on the spot, and are so abundant that the poorest people have always more food than is necessary. The butcheries of Merida supply Varinas and Pedraza. Excellent meat is at a very moderate price.

They fabricate here different articles in cotton and wool, the cheapness of which makes them preferred to those of Europe. Among these fabrics are carpets of the wool of the country, one ell long by rather more than half an ell wide, ornamented with flowers, and dyed on the spot with indigenous plants, whose red, green, blue, and yellow, are as bright and as lasting as those of our most famous manufactures.

The inhabitants, amounting to 11,500 persons, are of all colors and all classes. That of the negroes is perhaps the least numerous. That of the whites has long been divided into two parties; the Serradas and Guavirias, the names of the two principal founders of the city, who vowed a hatred against each other, which their descendants have preserved with much obstinacy, and cannot be said to be even yet perfectly extinguished.

The city, at the period when the late dreadful earthquake overwhelmed the city of Caraccas, shared the same fate, and was nearly destroyed; but has since been rebuilt and become more populous.

MERID'IAN, *n. s.* Fr. *meridien, meridional;* Ital. Span. and Port. *meridiano*; Lat. *meridies*. Noon; mid-day; the line which the sun crosses at noon; hence the highest point of power or attainment; any particular place or state: as an adjective, at the point of noon, or highest point; extended from north to south: meridional, after the French, is used for southern or southerly: meridionally is, in the direction of the meridian.

I've touched the highest point of all my greatness,
And from that full *meridian* of my glory
I haste now to my setting.
Shakspeare. Henry VIII.

All offices that require heat, as kitchens, stillatories, and stoves, should be *meridional*. *Wotton.*

Sometimes towards Eden, which now in his view
Lay pleasant, his grieved look he fixes sad;
Sometimes towards heaven, and the full blazing sun,
Which now sat high in his *meridian* tower. *Milton.*

All other knowledge merely serves the concerns of this life, and is fitted to the *meridian* thereof: they are such as will be of little use to a separate soul. *Hale.*

The true *meridian* is a circle passing through the poles of the world, and the zenith or vertex of any place, exactly dividing the east from the west. *Browne's Vulgar Errours.*

In the southern coast of America and Africa, the southern point varieth toward the land, as being disposed that way by the *meridional* or proper hemisphere. *Id.*

The Jews, not willing to lie as their temple stood, do place their bed from north to south, and delight to sleep *meridionally*. *Id.*

Your full majesty at once breaks forth
In the *meridian* of your reign. *Waller.*

Compare the *meridian* line afforded by magnetical needles with one mathematically drawn, observe the variation of the needle, or its declination from the true *meridian* line. *Boyle.*

He promised in his East a glorious race,
Now sunk from his *meridian*, sets apace.
Dryden.

The sun or moon, rising or setting, our idea represents bigger than when on the *meridian*. *Watts's Logick.*

Canst thou in whirlwinds mount aloft? canst thou
In clouds and darkness wrap thy awful brow?
And, when day triumphs in *meridian* light,
Put forth thy hand, and shade the world with night?
Young.

MERIDIAN, in astronomy, a great circle, supposed to be in the heavens exactly perpendicular to the terrestrial one. See ASTRONOMY.

MERIDIAN, in geography, is a great circle passing through the poles of the earth, and some given place on its surface. It therefore divides this surface into two hemispheres, the eastern and the western. As the terrestrial meridian is the circle over which the sun is at noon, it is consequently in the plane of the celestial meridian with which the centre of the sun coincides at that time. Now as, by the earth's revolution about its axis from west to east once in twenty-four hours, every part of the equator is successively presented to the sun, all places that are situated eastward or westward of each other have their respective meridians. It is, therefore, always the same hour of the day at all places situated on the same meridian.

The first meridian of a country is that from which its geographers, navigators, and astronomers, commence their reckoning of longitude; and, the meridians having nothing in themselves to distinguish them from each other, the fixing upon any one for this purpose is quite arbitrary; hence different persons, nations, and ages, have commenced their longitudes at different points, which has introduced no small confusion into geography. But national and even scientific jealousies are too strongly prevalent for us to hope that the world will at any early period fix on a common first meridian.

Longitudes were formerly reckoned from the island of Ferro; but, as each considerable country now usually adopts the meridian of its own capital as the first, the following longitudes reckoned from the Royal Observatory at Greenwich, will facilitate the conversion of the reckoning from one country to that of another.

MERIDIANI, in antiquity, a name given by the Romans to gladiators who entered the arena about noon, after the restiarii had finished; so called from the time when they exhibited their prowess. They were a sort of artless combatants, who fought man with man, sword in hand. Hence Seneca observes, that the combats of the morning with beasts were full of humanity, compared with those which followed.

MERIDIONAL DISTANCE, in navigation, the same with departure, or easting and westing; being the difference of longitude between the meridian, under which the ship now is, and any other meridian which she was under before.

MERIDIONAL PARTS, MILES, or MINUTES, in navigation, are the parts by which the meridians, in a Mercator's chart, increase as the parallels of latitude decrease.

MERIONETHSHIRE, a county of the principality, is called by the Welsh Meironydd, and is the only one in Wales that, with the addition of shire, still retains its ancient appellation. It was so denominated from Meirion the son of Tibiawn, and grandson of Cunedda, a noble British chieftain, who came to North Wales in the fifth century, for the purpose of assisting in rescuing it from the grasp of a set of marauding Irish, who, for the sake of plunder, had nearly overrun the country. Having succeeded in his enterprise, he obtained a large portion of territory as a boon, and gavelled out the possessions among his ten sons, and two grandsons Maelor and Meirion.

This district appears to have been known to the Romans, and was called by them Mervinia. It is a maritime county, lying on the Irish Sea, in which part of the large bay of Cardigan washes it on the west: and formerly beat against it with such violence, as to have made considerable encroachments. According to British history, a whole cantred or hundred, called Contre'r-Gwaelod, stretching west and south-west for twelve miles in length, and about five in breadth, was swallowed up and lost. On the north this county partly borders upon that of Caernarvon, it being separated from it by an immense ravine, through which the river Glass-lyn flows, and a bridge unites the two. A portion to the north also is divided by an alpine ridge, extending from beyond Rûg on the east to Llyn Elidyr on the west. Montgomeryshire lies to the east, and the river Dovey severs it from Cardigan on the south. Its length from Beddgelert near Snowdon to Bwlch y Vedwin, on the confines of Montgomeryshire, is forty-three miles; and, from Harlech to the extreme boundary of Llangollen parish, thirty-eight.

Merionethshire is extremely mountainous, and, though the mountains are not so high as those of the adjacent county of Caernarvon, yet many are very lofty; and others of a less towering height are, from their craggy nature, both picturesque and sublime. The principal mountains of this county are Cader Idris, little inferior in elevation to Snowdon; the two Arans, Penllyn, and Fowddwy; the two Arenigs; Moelwyn, and many of less consideration. Of the comparative heights of the chief among these, an account from actual admeasurement was furnished Mr. Pennant by an ingenious gentleman of Bala, which confutes the vague notion of Cadar Idris being one of the highest mountains in Britain. It states that the highest peak, called Pen y Cadar, is 950 yards higher than the green adjacent to the town of Dolgelley; Aran Fowddwy 740 yards above Llyn Tegid; and the loftiest Arenig only twenty less than the Aran. The fall from the lake of Dolgelley Green is 180 yards, consequently the actual difference in height between the Cadar and the Aran amounts to thirty yards.

The rivers of this county are, the Dee, formed by two small rivulets which rise from springs on the side of Aran Pen-llyn, and, quickly uniting their streams, enter the lake called by the Welsh Llyn-tegid, and by the English Pimble Mere. After quitting Llyn-tegid, this river flows through the beautiful vale of Eidernion, and, passing the small town of Corwen, leaves this county and enters that of Denbigh. The Maw, or Mawddach, rises about the centre of the county, and running due south, to Dolgelly, receives the tributary Eden; and after becoming a tide estuary, and changing its course to the westward, falls into the Irish Sea at Abermaw, Anglicised into Barmouth. The Dovey, or Dyfi, has its origin at the foot of the mountainous ridge through which the celebrated pass Bwlch y Groes forms a communication with the adjacent parts of Montgomeryshire; thence taking a southerly direction, by Dinas y Mawddu, it waters part of that county as far as Machynlleth, when it re-enters Merionethshire, and, becoming a wide estuary, delivers its waters to the ocean below Aberdovey. The Glaslyn and Dwy'rid conjointly flow to the sea by the Traeth-mawr and Traeth-bychan. Numerous other rivulets and streams, chiefly supplied by mountain torrents, branch off and fertilise the numerous narrow valleys through which they flow. The principal lakes are Llyn-tegid, near Bala, and Llyn-talyllyn at the foot of Cader Idris Mountain. To these may be added Llyn Elider, Llyn Telwyn echa and isa, Llyn y Cwmbychan, Llyn Arrenig, &c.

The soil of this county is various. The mountains consist principally of granite, porphyry, and other unstratified rocks; while the secondary hills are composed of primitive or mixed schistus. The valleys contain schistose clay, and more level parts of the county abound with peat-earth, forming bogs and turbaries. From such a statement, this county may be expected to rank high in an agricultural point of view. The chief attention therefore of the inhabitants is confined to breeding and the dairy. The pastures in the valleys afford sustenance to numerous herds of horned cattle; and the hills, though the grass is coarse, are nearly clothed to their summits, furnishing most extensive sheep walks; and large flocks of sheep are seen to depasture their sides, while numerous goats browse among the adjacent crags. The peat-bogs produce turf of an excellent quality which is the principal fuel of the district. Several of the mountains are private property; and the demarcation of the different demesnes is made by dry walls, carried in many instances up to the very tops. This appears to be the case in some instances where, from the nature of the surface and the sharpness of the escarpment, they seem to set all cultivation at defiance. The average of the county has been rated at 430,000 acres; out of which 286,000 may be unenclosed, and of that number about 35,000 may be called improvable wastes. All the marshes on the sea coast, from Aberyvi on the confines of Cardiganshire to Pont Aberglaslyn on that of Caernarvonshire, are of this description. Though Merioneth cannot vie with the adjacent counties, yet considerable improvements have been made by several landed proprietors within a few years past.

It has been remarked, that the original Welsh roads, generally ascending the brow of the hill, are strikingly descriptive of the national character. The method of surmounting difficulties, in this respect, appears to have been rather by a daring spirit, than the arts of circumvention. Almost every valley and dale had a road winding round its bottom, till at the extremity a mountain barrier presented itself, which was to be passed over a sudden ascent by a path like a step-ladder. A striking instance of this still remains in the abrupt passes Bwlch y Groes near Llanynowdden, and Bwlch Verddrws near Dolgelley; and the force of the remark to no district so strongly applies as to this. But it should be observed that this country is of great extent, and the mountainous parts far exceed the plain or cultivated lands. This forms a strong obstacle in the first formation or the future improvement of the roads; for the original expense must necessarily be great, and the tolls collected at the different gates comparatively small, owing to the thinness of population and the low state of agriculture. To the credit of the county, however, the magistrates have greatly exerted themselves; and spirit with perseverance has performed much. About 200 miles of new or improved roads have been formed within the county within the space of the last thirty-seven years. Among these may be noticed the fine road from Dolgelly to Barmouth, and more especially the one from Pont Aberglaslyn towards Tan y Bwlch At the former, near the celebrated salmon-leap, the great road from Caernarvon to the south entered this county; and the portion of it between the two places was extremely difficult to pass. The traveller was necessitated either to climb alpine staircases, or, what was equally unpleasant and dangerous, to seek a guide to conduct him by the circuitous route over the Traethe-mawr sands; and, as this could only be effected at ebb tides, he was often detained for a day or night. This obstruction has now been removed by forming a new road from the bridge to Tan y Bwlch. This, winding round the mountain upon various levels, and from the beauty and grandeur of the surrounding scenery, is now considered as one of the most pleasant and diversified rides in the principality. This grand link connects a chain of roads through the whole extent of Wales, from the head of Holy Cibi in the north to that of the patron St. David in the south.

Leland observes, that several parts of the county in his time had 'meat by good plenty of wood;' so that this product of the county must have failed, as well as agriculture been neglected. But the failure in this respect is more easily accounted for than the retrograde state of husbandry, an art and practice so intimately connected with the necessaries of life. Respecting the former, avarice will easily solve the difficulty. Though this might at a subsequent period have been once as naked of woods as any in Wales, yet it is certainly at present better clad. A spirit of planting has for years pervaded the breasts of the great landholders, and still continues to increase the sylvan beauty of the county.

The manufactures of this county principally consist of woollen goods, such as strong cloths, druggets, kerseymeres, flannels, stockings, gloves, wigs, &c., made of the country wool furnished by the numerous and extensive sheep walks. This county is divided into five hundreds, containing thirty-seven parishes, and five market towns. This county, as to its ecclesiastical government, is included within the diocese of Bangor, and returns one member to the imperial parliament for the shire.

MER'IT, *n. s.* & *v. a.* Fr. *merite*, *meriter*, MERITO'RIOUS, *adj.* *meritoire*, of Lat. MERITO'RIOUSLY, *adv.* *meritum*. Desert; MERITO'RIOUSNESS, *n. s.* reward; claim; right; used generally of good, but sometimes of ill desert; hence to deserve or earn: meritorious is deserving; high on the scale of worth or desert.

Instead of so great and *meritorious* a service, in bringing all the Irish to acknowledge the king for their liege, they did great hurt. *Spenser on Ireland.*

You have the captives; use them
As we shall find their *merits* and our safety
May equally determine. *Shakspeare. King Lear.*

Whatsoever jewels I have *merited*, I am sure I have received none, unless experience be a jewel, that I have purchased at an infinite rate.
Id. Merry Wives of Windsor.

The war that hath such a foundation will not only be reputed just, but holy and *meritorious*.
Raleigh's Essays.

He carried himself *meritoriously* in foreign employments in time of the interdict, which held up his credit among the patriots. *Wotton.*

We can never fully enough comprehend in our thoughts the joys of heaven, the *meritorious* sufferings of Christ, the terrors of the second death; therefore we must meditate of them often. *Bp. Hall.*

Sufficient means of redemption and salvation, by the satisfactory and *meritorious* death and obedience of the incarnate Son of God, Jesus Christ, God blessed for ever. *Sanderson.*

Amply have *merited* of me, of all
The' infernal empire.
Milton's Paradise Lost.

She deemed I well deserved to die,
And made a *merit* of her cruelty. *Dryden.*

A man at best is incapable of *meriting* any thing from God. *South's Sermons.*

There was a full persuasion of the high *meritoriousness* of what they did; but then there was no law of God to ground it upon, and consequently it was not conscience. *South.*

This is not only the most prudent, but the most *meritorious* charity, which we can practise. *Addison.*

Those laurel groves, the *merits* of thy youth,
Which thou from Mahomet didst greatly gain,
While bold assertor of resistless truth,
Thy sword did godlike liberty maintain. *Prior.*

Roscommon, not more learned than good,
With manners generous as his noble blood;
To him the wit of Greece and Rome was known,
And every author's *merit* but his own. *Id.*

She valued nothing less
Than titles, figure, shape, and dress.
That *merit* should be chiefly placed
In judgment, knowledge, wit, and taste.
Swift.

When a point hath been well examined, and our own judgment settled, after a large survey of the *merits* of the cause, it would be a weakness to continue fluttering. *Watts.*

What numbers live to the age of fifty or sixty years! yet, if estimated by their *merit*, are not worth the price of a chick the moment it is hatched. *Shenstone.*

Real friendship is a slow grower; and never thrives, unless engrafted upon a stock of known and reciprocal *merit*. *Chesterfield.*

Then, conscious of her *meritorious* zeal,
To justice she may make her bold appeal.
Cowper.

MER'LIN, *n. s.* Barb. Lat. *merillus*; Belg. *smerlin*. A kind of hawk.

Not yielding over to old age his country delights, he was at that time following a *merlin*. *Sidney.*

MERLIN (Ambrose), a famous English poet and reputed prophet, who flourished about A. D. 480. Many surprising and ridiculous things are related of him. Several English authors have represented him as the son of an incubus, and as transporting from Ireland to England the great stones which form Stonehenge. Extravagant prophecies and other works are also attributed to him, on which some authors have written commentaries.

MER'MAID, *n. s.* Goth. *mar*, the sea, and maid. A sea woman; an animal, real or supposed, with a woman's head and fish's tail.

Thou remembrest,
Since once I sat upon a promontory,
And heard a *mermaid* on a dolphin's back
Uttering such dulcet and harmonious breath,
That the rude sea grew civil at her song.
Shakspeare.

Did sense persuade Ulysses not to hear
The *mermaids'* songs, which so his men did please,
That they were all persuaded, through the ear,
To quit the ship and leap into the seas? *Davies*

Few eyes have escaped the picture of a *mermaid* Horace's monster, with woman's head above, and fishy extremity below, answers the shape of the ancient syrens that attempted upon Ulysses.
Browne's Vulgar Errours.

MERODACH, an ancient king of Babylon, who was placed among the gods, and worshipped by the Babylonians. See Jerem. l. 2. We find several kings of Babylon of whose names Merodach makes a part, as Evilmerodach and Merodach-Baladan. See EVILMERODACH and BALADAN.

MERODACH-BALADAN, son of Baladan king of Babylon, is called by Ptolemy Mardocempadus. He says that he began to reign a Babylon twenty-six years after the beginning of the era of Nabonassar, A. M. 2283.

MEROE, in ancient geography, an island of Ethiopia, beyond Egypt, in the Nile, with a cognominal town, the metropolis of the Ethiopians. The Jesuits have endeavoured to prove that the province of Gojam in Abyssinia is the Meröe of the ancients; but Bruce has proved, almost beyond a doubt, that the peninsula of Athara formerly bore that name. Diodorus Siculus says that Meröe had its name from a sister of Cambyses king of Persia, who died there in the expedition undertaken by that prince against the Ethiopians. His army perished with hunger and thirst in the deserts beyond Meröe; which could not have happened if they had reached Gojam, the latter being one of the most plentiful countries in the world. A further proof that Gojam cannot be the ancient Meröe is, that the latter was enclosed between the Nile and Astaboras, while Gojam is almost entirely surrounded by the Nile. If the ancients were acquainted with Gojam, they must also have been acquainted with the fountains of the Nile, which we know they were not. Pliny says that Meröe, the most considerable of all the islands of the Nile, was called Astaboras, from the name of its left channel, which cannot be supposed any other than the junction of the Nile and Atbara. Again, the poet Lucan describes Meröe by two circumstances which cannot apply to any other than the peninsula of Atbara. One is, that the inhabitants were black, which was the case with the Gymnosophists and first inhabitants, and which has been the case with all the rest down to the Saracen conquest; but the inhabitants of Gojam, as well as the other Abyssinians, are fair, at least greatly different in complexion from the blacks; they are also long haired. The other is, that the ebony tree grew in the island of Meröe, which still grows plentifully in the peninsula of Atbara, but not in Gojam, where it could not subsist on account of the violent rains during six months of the year.

MEROM, or MEROME, in ancient geography, the waters of Merom, the place at which Jabin and the other confederate kings met to fight Joshua (xi. 5), generally supposed to be the lake Semechon, which lies between the head of the Jordan and the lake Gennesareth; as it is gene-

rally agreed that Hazor, where Jabin reigned, was situated upon this lake. Others think, with considerable probability, that the waters of Merom were somewhere about the brook Kishon, a place of that name being mentioned in Judges v. 21, where the account of the battle is recorded.

MEROPE, in fabulous history, one of the Atlantides. She married Sisyphus the son of Æolus, and like her sisters was changed into a star, in the constellation Pleiades, after death. It is said that in this constellation the star of Merope appears more dim and obscure than the rest, because she married a mortal, while her sisters married some of the gods or their descendants.

MEROPS, in fabulous history, a king of the island of Cos, who married Clymene, one of the Oceanides. He was changed into an eagle, and placed among the constellations.

MEROPS, a celebrated soothsayer of Percosus in Troas, who foretold the death of his sons Adrastus and Amphius, who were engaged in the Trojan war. They slighted their father's advice, and were killed by Diomedes.

MEROPS, in ornithology, a genus belonging to the order of picæ. The bill is crooked, flat, and carinated; the tongue is jagged at the point; and the feet are of the walking kind. There are twenty or thirty species.

1. M. apiaster, the bee-eater, has an iron-colored back; the belly and tail are of a bluish-green; and the throat is yellow. This species inhabits various parts of Europe, on the continent, though not in England; yet has been seen in Sweden. They are now and then seen in Lorraine, though only in pairs; and are frequent in other parts. Kramer talks of their building nests in the sandy crags of the Danube. They are met with in Italy and the south of France; and in Candia and other islands of the Mediterranean they are numerous, as well as in Palestine and Arabia, being very common in the woods about Yemen, where they are called schæghagha. It takes the name of bee-eater from its being very fond of those insects: it will also catch gnats, flies, cicadæ, and other insects, on the wing, like the swallow. Willoughby tells us, from Belon, 'that its singular elegancy invites the Candian boys to hunt for it with cicadæ, as they do for swifts, in this manner:—Bending a pin like a hook, and tying it by the head to the end of a thread, they thrust it through the cicada (as boys bait a hook with a fly), holding the other end of the thread in their hands: the cicada, so fastened, flies nevertheless in the air; which the Merops spying, flies after it with all her force; and, catching it, swallows pin and all, wherewith she is caught.' This species is said to be most plentiful in the isle of Candia; and, in defect of insects, to eat seeds of many kinds; and Ray supposes, from its similarity to the kingfisher, it may possibly feed on fish. Willoughby saw many of them exposed for sale in the markets of Rome. These birds make their nests in deep holes on the banks of rivers, like the kingfisher, at the end of which the female lays from five to seven white eggs, rather smaller than those of a blackbird. The nest itself is composed of moss.

2. M. erythropterus, the red-winged bee-eater, is in length six inches; the bill is one inch, and black; the upper parts of the head, body, wings, and tail-coverts, are green brown, deepest on the head and back, lightest on the rump and tail-coverts; behind the eye is a spot of the same, but of a very deep color; the quills and tail are red, tipped with black; the last two inches in length; the throat is yellow, the under parts of the body are a dirty white; and the legs black. This species inhabits Senegal, from which place a well preserved skin was brought by M. Adanson.

3. M. Novæ Hollandiæ, the wattled bee-eater, is the size of a cuckoo, in length about fourteen inches and a half. The feathers on the upper part of the head, being longer than the rest, give the appearance of a crest; those of the under part are smooth; the plumage for the most part is brown; the feathers are long and pointed, and each feather has a streak of white down the middle; under the eye, on each side, is a kind of wattle, of an orange color; the middle of the belly is yellow; the tail is wedge-shaped, similar to that of the magpie, and the feathers are tipped with white; the bill and legs are brown. This species is said to be peculiar to New Holland.

4. M. superciliosus is green, with a white line both above and below the eyes, and a yellow throat. It is found in Madagascar, where the natives call it patirich-tirich.

MEROVINGIAN CHARACTER, an ancient character much used under the Merovingian race of French kings. There are many MSS. in the French libraries, still extant in this character.

MEROVINGIAN RACE, the most ancient race of the French kings, so named from Meroveus, the third king of France of that race, which reigned 333 years, from Pharamond to Charles Martel. This race terminated in Childeric III. A. D. 751. See FRANCE.

MERRIMACK, a river of North America, which rises in New Hampshire. The most northern branch, the Pemigewasset, rises from the White Mountains and Moosehillock, and, after a southerly course of about seventy miles, is joined by the Winnipiseogee at Sanborntown, and then takes the name of Merrimack. The course continues southerly about eighty miles, as the river runs, when it reaches Massachusetts line. It then turns to the east, and, after a course of about fifty miles, falls into the Atlantic below Newburyport. It is navigable for vessels of 200 tons to Haverhill. By means of this river, and the Middlesex Canal, an extensive boat navigation is opened between Boston and the state of New Hampshire, as far as Concord. The principal falls on the Merrimack, around which canals are constructed, are Isle of Hookset, Amoskeag, and Patucket.

MER'RY, *adj.*
MER'RILY, *adv.*
MER'RY-MAKE, *n. s.* & *v. n.*
MER'RIMENT, *n. s.*
MER'RINESS,
MER'RY-ANDREW,
MER'RY-THOUGHT,

Probably Sax. mepnian, gladness. Teut. *mere*, *meyr*, has a similar signification. Gay; jovial; loudly cheerful; causing laugh-

ter; prosperous. To make merry' is to be jovial, or extremely cheerful: a merry-make is a festival; meeting for mirth; mirthful pranks: to merry-make, to feast; be jovial: merriness and merriment mean gaiety; laughing, or loud mirth; gay disposition: a merry-andrew is a buffoon, or harlequin: merry-thought, a forked bone on the body of fowls, so called because young people pull in play at the two sides, the longest part broken off betokening priority of marriage.

They drank and were *merry* with him.
Gen. xliii. 34.

They trod the grapes and *made merry*, and went into the house of their God. *Judg.* ix. 27.

Thenot now nis the time of *merrymake*,
Nor Pan to herie, nor with love to play,
Sike mirth in May is meetest for to make,
Or Summer shade, under the cocked hay.
Spenser.

The knight did not forbear,
Her honest mirth and pleasure to partake;
But when he saw her gibe, and toy, and geare,
And pass the bounds of modest *merrimake*,
Her dalliance he despised. *Faerie Queene.*

Who, when they heard that piteous strained voice,
In haste forsook their rural *merryment*. *Id.*

A number of *merriments* and jests, wherewith they have pleasantly moved much laughter at our manner of serving God. *Hooker.*

You killed her husband, and for that vile fault
Two of her brothers were condemned to death;
My hand cut off, and made a *merry* jest.
Shakspeare.

Merrily, merrily, shall we live now,
Under the blossom that hangs on the bough. *Id.*

The stile shall give us cause to climb in the *merriness*. *Id.*

Some, that are of an ill and melancholy nature, incline the company into which they come to be sad and ill-disposed; and others, that are of a jovial nature, do dispose the company to be *merry* and cheerful.
Bacon's Natural History.

Methought it was the sound
Of riot and ill-managed *merryment*. *Milton.*

A paisan of France thinks of no more than his coarse bread and his onions, his canvass clothes and wooden shoes, labours contentedly on working days, and dances or plays *merrily* on holidays.
Temple's Miscellanies.

In my small pinnace I can sail,
Contemning all the blustering roar;
And, running with a *merry* gale,
With friendly stars my safety seek
Within some little winding creek,
And see the storm ashore. *Dryden.*

A fox 'spied a bevy of jolly, gossipping wenches, *making merry* over a dish of pullets. *L'Estrange.*

He would be a statesman because he is a buffoon; as if there went no more to the making of a counsellor than the faculties of a *merry-andrew* or tumbler.
Id.

The *merry* part of the world are very amiable, while they diffuse a cheerfulness through the conversation, at proper seasons, and on proper occasions.
Addison.

Man is the *merriest* species of the creation; all above and below him are serious. *Id.*

With thee 'twas Marian's dear delight
To moil all day, and *merrimake* at night. *Gay.*

Let him not be breaking *merrythoughts* under the table with my cousin. *Echard.*

Merrily sing, and sport, and play,
For 'tis Oriana's nuptial day. *Granville.*

MERRY (Robert), an English poet educated under the celebrated Dr. Barr at Harrow, and afterwards at Christ Church Oxford. He purchased a commission in the guards, and published several esteemed pieces, under the title of Della Crusca; and his tragedy of Lorenzo was acted at Covent Garden. He married Miss Brunton, an actress, with whom he went to America, where he died in 1798.

MERRYMEETING BAY, a bay of Maine, United States, formed by the junction of the rivers Androscoggin and Kennebeck, on the west side of Woolwich, and north of Bath, eighteen miles from the sea.

MERS EL KEBEER, or MAZALQUIVER, a seaport of Algiers, anciently called, from its great extent, Portus Magnus, was taken by the Spaniards in 1705, lost by them in 1708, but recovered in 1732. It is defended by a large but weak fort. Six miles west of Oran.

MERSA, a town of Barbary, pleasantly situated about eleven miles from Tunis, and two from Melcha, the site of ancient Carthage. The bey has two country houses, one of them very costly work, built by Hassan Bey. From these are orange gardens reaching almost to the shore; on the edge of which is a famous well of sweet water, esteemed the best in the kingdom. Close to this is a coffee-house, whither numbers of people from the neighbouring places resort to drink coffee, and a glass of this natural luxury so peculiarly enjoyed in the eastern countries. In the middle of the court is a large mulberry tree, under the shade of which they sit, smoke, and play at chess, inhaling the comfortable sea breeze that refreshes this delightful spot. The water is drawn up by a camel with the Persian wheel. Here are the remains of an ancient port (supposed to be artificial) built by the Carthaginians, after Scipio had blocked up the old port, nothing but the turret, or light-house, being left.

MERSEBURG, one of the new governments of Prussia, containing that part of Saxony which lies to the south of Anhalt, and to the east of Erfurt; and comprises the chief part of the old electoral circle of Saxony; a small part of Thuringia; the bishoprics and chapter lands of Merseburg, Naumburg, and Zeitz; part of the duchy of Magdeburg; part of the districts of Leipsic and Meissen; with the counties of Mansfeld and Stolberg. The river Unstrut forms part of its western boundary. It consists almost entirely of cessions made by Saxony in 1815; the united territories composing a total of 4000 square miles, with 471,000 inhabitants, divided into seventeen districts or circles.

MERSENNE, or MERSENNUS (Marin), a learned French author, born at Oyse, in the province of Maine, in 1588. He studied at La Fleche with Des Cartes, with whom he contracted a friendship which lasted till death. He afterwards went to Paris, and studied at the Sorbonne; and in 1611 entered among the Minims. He became well skilled in Hebrew, philosophy, and mathematics. He was of a tranquil, sincere, and engaging temper; and was universally esteemed. He taught philosophy and divinity in the convent of Nevers, and at length became superior of it; but, wishing to

study with more freedom, he resigned all the posts in his order, and travelled into Germany, Italy, and the Netherlands. He wrote a great number of excellent works, the principal of which are, 1. Questiones Celeberrimæ in Genesim. 2. Harmonicorum Libri. 3. De Sonorum Naturâ, Causis, et Effectibus. 4. Cogitata Physico-mathematica. 5. La Verité des Sciences. 6. Les Questions Inouies. He died in Paris in 1648.

MERSEY, a river of England, that runs through the counties of Lancaster, York, and Chester, and falls into the Irish Sea at Liverpool. It receives numerous accessions in its course, of which the principal are the Irwell from Manchester, and the Weaver from Cheshire, and spreads out into a wide but shallow channel. It is navigable up to the Irwell, and affords salmon, and shoals of smelts called sparlings, of remarkable size and flavor.

MERSEY ISLAND, an island of Essex, at the mouth of the Coln, south of Colchester. It was seized by the Danes in the reign of king Alfred, for their winter quarters. It had eight parishes, now reduced to two, viz. east and west Mersey. It had a block-house; and during the Dutch war, the parliament put 1000 men in it.

MER'SION, *n. s.* Lat. *mersio.* The act of sinking, or thrusting over head.—*Ainsworth.*

MERTHYR TYDVILL, a market town of Glamorganshire, situated in the midst of an extensive mining district, and at the distance of about 180 miles west from London, and twenty-four N. N. W. from Cardiff. It was formerly but a small village, and though now the principal trading town of Wales is meanly and irregularly built, having no connected streets. It owes its prosperity entirely to the mines in its vicinity, which consist principally of coal and iron. The agricultural improvements of the neighbourhood may be traced to the same origin, the vast quantities of manure produced by the horses, &c., employed in the mines, enabling the farmer to raise his land to the highest pitch of cultivation. It is supposed that there are forged weekly within ten miles of this town upwards of 1000 tons of iron. There are also several lead mines supposed to have been worked as far back as the times of the Romans. This town has a new church, a theatre, several dissenters' chapels, and two reading societies; and a fine canal has been cut from this place to Cardiff. On the top of a mountain, three miles distant, north, are the ruins of Merlais Castle, said to have been the residence of the kings of Brecknock. This town sends one member to parliament.

MERULA (George), an Italian of extraordinary parts and learning, born at Alexandria about 1420. He taught youths at Venice and Milan for forty years, and labored much in restoring and correcting ancient authors. He wrote, and addressed to Louis Sforza, Antiquitates Vicecomitum, &c., or the Actions of the Dukes of Milan, in ten books, with some other pieces. He died in 1494, unlamented, as he had abused almost all his contemporary scholars.

MERULA (Paul), born at Dort in Holland, a famous lawyer, historian, and linguist, was professor of history in the university of Leyden after Lipsius. He wrote, 1. Commentaries on Ennius; 2. The Life of Erasmus and Junius; 3. A Cosmography; 4. A Treatise of Law; and died in 1607.

MERULA, in ornithology. See TURDUS.

MERUS, in ancient geography, a mountain of the Hither India, hanging over the city Nyssa, built by Bacchus, and situated between the rivers Cophen and Indus. The name, denoting the thigh, gave rise to the fable of Bacchus being sewed up into Jupiter's thigh, and being born twice; because in this mountain he and his army are said to have been preserved, when disease and pestilence raged in the plains below.

MERU SHAH JEHAN, the ancient Antiochia, a city of Korassan, in Persia, capital of Margana, on the river Murghab. It was one of the four imperial cities of this country, and the capital of many of the Persian sultans of the Seljukian dynasty. It was then surrounded by the beautiful gardens, the fruits of which were accounted most exquisite. Alp Arslan, the most powerful prince of his time, reigned here for a number of years. About twenty years ago this capital was taken and pillaged by the Uzbecks, since which time it has gradually declined. The population is not at this time above 3000. It is 130 miles north-east of Mesched.

MERSEBURG, an old town of Prussian Saxony, the capital of a government of the same name, stands fifteen miles west of Leipsic, on the Saale, and has narrow crooked streets; but they are clean and well paved. The cathedral, which has a fine organ, the gymnasium, and the palace of the bishops and dukes, are worth notice. Brewing is largely carried on here. Population 6800.

MESCHED, a city of Korassan, the capital of the Persian port of that province, is chiefly distinguished by a noble mausoleum, containing the remains of Imam Reza and the celebrated Caliph Haroun Al Raschid. It is called a 'holy city,' and surrounded with a wall seven miles in circuit. There is also an inferior palace here called 'the ark,' and a bazaar three miles in length, which is well supplied with fruits and vegetables. The houses are in general mean, but the inhabitants are said to amount to 50,000. Beautiful velvet pelisses and fur are manufactured here, and a considerable trade is carried on with Bukhara, Kandahar, Herat, and Yeza. It is about five miles from the ancient Tous, in long. 57° E., and lat. 37° 35′ N.

MESCHED ALI, or NEJETT, a town of Irak Arabi, containing the burial place of the caliph Ali, a noble structure, encircled by a high wall, within which it is death for an infidel to be found. The dome is light and elegant, and, together with the tops of the minarets, was gilded at the expense of Nadir Shah. The town is entirely supported by the influx of Persian pilgrims and devotees. The environs are barren, and rendered gloomy by the number of graves which cover them; persons of consequence being brough here for interment from the most remote parts of Persia. Ninety miles south of Bagdad.

MESCHIE, or MENSHEEL, a town of Upper

Egypt. The ancient Ptolemais, immediately opposite to Achmim. It enjoys a considerable trade, as the vessels between Cairo and the cataracts usually stop here for provisions. There are very fine pigeon-houses in the neighbourhood.

MESEEMS', *impers. v.* Me and seems, or it seems to me. For this word, says Dr. Johnson, it is now too common to use methinks or methought, an ungrammatical word. I think; it appears to me; methinks.

Alas! of ghosts I hear the ghastly cries;
Yet there, *meseems*, I hear her singing loud.
Sidney.

Meseemed by my side a royal maid,
Her dainty limbs full softly down did lay.
Faerie Queene.

To that general subjection of the land *meseems* that the custom or tenure can be no bar nor impeachment. *Spenser.*

MESEMBRYANTHEMUM, fig marigold, in botany, a genus of the pentagynia order and icosandria class of plants; natural order thirteenth, succulentæ: CAL. quinquefid; the petals are numerous and linear: CAPS. fleshy, inferior, and monospermous. There are between forty and fifty species, all African plants, from the Cape of Good Hope; nearly forty of which are retained in gardens for variety. Of these only one, viz.

M. crystallinum, the diamond ficoides or ice plant, is annual, and the most remarkable of them all. It rises with a short, thick, succulent stalk, dividing low into many trailing, very spreading, succulent branches, bespangled all over with icy pimples; very pellucid and glittering; oval, undulate, alternate, papulose or pimply, glittering leaves; and from the sides of the branches, numerous, almost close sitting, white flowers, tinged with red or crimson; succeeded by plenty of seed in autumn. This singular and curious plant, being closely covered with large pellucid pimples, full of moisture, shining brilliantly, is in great esteem. It is a very tender plant while young; and is raised annually from seed in hot-beds. In June it will endure the open air till October, when it perishes; but if placed in a hot-house in autumn, it will often live all winter. It is commonly planted in pots for the conveniency of removing; but if planted in full ground, it grows considerably stronger, even to luxuriance: however, when confined in pots, it flowers more abundantly. The other species are most durable in stem and foliage. Some are shrubby; others pendulous, with loose straggling stems, and branches inclining to the ground; while others have no stalks at all: their leaves are universally very thick, succulent, fleshy, and of many various shapes, situations, and directions; while some are curiously punctured, or dotted with transparent points, and some have pellucid pimples, as already mentioned: they afford a very agreeable variety at all times in the year, and merit a place in every collection. They are green-house plants, and are propagated by cuttings of their stalks and branches.

MESEN, a town of European Russia, on the Mesen, in the government of Archangel. It is the chief town of a circle, which includes the region of Nova Zembla. Its chief trade is in fish, whale-oil, and sea-dogs. Population 2000. 138 miles E. N. E. of Archangel, and thirty from the mouth of the river.

MESEN, a large river of European Russia, rising in the government of Archangel: after numerous windings it takes a N. N. W. direction, and falls into the White Sea.

MESENGUY (Francis Philip), a French divine, born at Beuvais in 1677. He wrote, 1. Exposition de la Doctrine Chretienne, 6 vols. 12mo., which was condemned by Pope Clement XIII. 2. Abregé de l'Histoire et de la Morale de l'Ancien Testament, 12mo. 3. Abregé de l'Histoire de l'Ancien Testament, 10 vols. 12mo. 4. Some tracts on the bull Unigenitus. He died in 1769.

MESENTERY, MESENTERIUM, is so called from μεσος, middle, and εντερον, intestine, as being placed in the middle of the intestines, which it connects to one another. See ANATOMY, Index.

MES'ERAICK, *n. s.*, MESEN'TERY, *n. s.*, MESENTER'IC, *adj.* } Fr. *meseraique, mesentere, mesenterique;* Gr. μεσαραιον. Belonging to the mesentery; this is also the meaning of mesenteric: the mesentery, a part of the PERITONEUM, which see.

It taketh leave of the permanent parts at the mouths of the *meseraicks*, and accompanieth the inconvertible portion into the siege. *Browne.*

The most subtile part of the chyle passeth immediately into the blood by the absorbent vessels of the guts, which discharge themselves into the *meseraick* veins. *Arbuthnot.*

When the chyle passeth through the *mesentery*, it is mixed with the lymph. *Arbuthnot on Aliments.*

They are carried into the glands of the *mesentery*, receiving a fine lymph from the lymphatick ducts, which dilutes this chylous fluid, and scours its containing vessels, which, from the *mesenterick* glands, unite in large channels, and pass directly into the common receptacle of the chyle. *Cheyne.*

MESERITZ, or MIENDZYRZECZ, a town of Prussian Poland, on the borders of Silesia, in a fruitful district, between the Obra and the Packlitz. Population 3600. Fifty-five miles west of Posen.

MESH, *n. s.* & *v. a.*, MESH'Y, *adj.* } Old Fr. *mache.* See MASH. The interstice of a net: to ensnare or catch in a net: meshy is reticulated; worked as a net.

Such a hare is madness the youth, to skip o'er the *meshes* of good counsel the cripple. *Shakspeare.*

The flies by chance *mesht* in her hair,
By the bright radiance thrown
From her clear eyes, rich jewels were,
They so like diamonds shone. *Drayton.*

The drovers hang square nets athwart the tide, thorough which the shoal of pilchard passing, leave many behind entangled in the *meashes.* *Carew.*

Some build his house, but thence his issue barre,
Some make his *meshy* bed, but reave his rest. *Id*

He spreads his subtle nets from sight,
With twinkling glasses to betray
The larks that in the *meshes* light. *Dryden.*

With all their mouths the nerves the spirits drink,
Which through the cells of the fine strainers sink:
These all the channel'd fibres every way,
For motion and sensation, still convey:
The greatest portion of the' arterial blood,
By the close structure of the parts withstood,
Whose narrow *meshes* stop the grosser flood.
Blackmore.

Caught in the *meshy* snare, in vain they beat
Their idle wings. *Thomson.*

MES'LIN, *n. s.* Fr. *mesler*, to mix; or corruptly pronounced for *mescellane*. See MASLIN. Mixed corn.

If worke for the thresher ye mind for to have,
Of wheat and of *mestlin* unthreshed go save.
Tusser.

What reason is there which should but induce, and therefore much less enforce, us to think, that care of old dissimilitude between the people of God and the heathen nations about them, was any more the cause of forbidding them to put on garments of sundry stuff, than of charging them withal not to sow their fields with *meslin*? *Hooker.*

MESNARDIERE (Hippolytus Julius Pilet de la), a French poet, born in 1610. He was partronised by cardinal Richelieu, and was a member of the French Academy. He published, 1. A Treatise on Melancholy. 2. Alinde; and 3. The Maid of Orleans, tragedies; 4. Poetique; and 5. A Collection of Poems. He died in 1663.

MESNE, or MESN, a term in law, signifying him who is lord of a manor, and so hath tenants holding of him; yet he himself holds of a superior lord. The word is derived from maisne, quasi minor natu; because his tenure is derived from another, of whom he holds.

MESNE, a writ, which lieth where there is lord mesne and tenant; and the tenant is distrained for services due from the mesne to the superior lord. This is in the nature of a writ of right; and in this case the tenant shall have judgment to be acquitted or indemnified by the mesne lord; and if he make default therein, or do not appear originally to the tenant's writ, he shall be forejudged of his mesnalty, and the tenant shall hold immediately of the lord paramount himself.

MESOCHRI, musicians among the ancients, who presided in concerts, and, by beating a wooden desk regularly with their feet, directed the measure of the music. For the purpose of beating time, they wore wooden clogs, called by the ancients crupezia, which occasioned the sound to be better heard.

MESOCOLON, in anatomy, that part of the mesentery, which, having reached the extremity of the ilium, contracts, and changes its name. See ANATOMY.

MESO-LOGARITHMS, *n. s.* A term used by Kepler for the logarithms of cosines and tangents. See LOGARITHMS.

MESOPORPHYRON, a name given by the Greeks to the Roman laticlave; because that garment, being edged on each side, where it opened before, with purple, appeared when closed with two purple stripes down the middle. The same term was also applied to the angusticlave.

MESOPOTAMIA, the ancient name of the province of Diarbeck, in Asiatic Turkey. It is situated between the Euphrates and Tigris; having Assyria on the east, Arabia Deserta with Babylonia on the south, Syria on the west, and Armenia on the north. The Hebrews called it Padan-aram (Gen. xxviii. 2, &c.), and Aram Naharaim (Psalm lx.) or Aram of the two rivers, because it was first peopled by Aram the ancestor of the Syrians, and is situated between the two rivers above mentioned. This country is much celebrated in Scripture, as being the first dwelling of men both before and after the deluge; and because it gave birth to Peleg, Heber, Terah, Abraham, Nahor, Sarah, Rebekah, Rachel, Leah, and the sons of Jacob. Babylon was in the ancient Mesopotamia, and, by vast labor and industry, the two rivers of the Tigris and Euphrates were united into one channel. The plains of Shinar were in the same country. Often they gave it the name of Mesopotamia (Deut. xxiii. 4, &c.), and sometimes that of Syria (Hosea xii. 12). Balaam son of Beor was of Mesopotamia (Deut. xxiii. 4). Chushan-rishathaim king of Mesopotamia kept the Hebrews in subjection some time after the death of Joshua, Judg. iii. 8.

MESPILUS, the medlar, in botany, a genus of the pentagynia order, and icosandria class of plants; natural order thirty-sixth, pomaceæ: CAL. quinquefid; the petals are five; the berry is inferior and pentaspermous.

1. M. amelanchier, the shrubby medlar, with black fruit, rises with several shrubby, slender, hairy stems, branching moderately about four feet high, having purplish branches; oval serrated leaves, downy underneath; and small white flowers in clusters at the ends of the branches; succeeded by small black fruit.

2. M. arbutifolia, arbutus-leaved mespilus, has a shrubby stem, branching five or six feet high; lanceolate, crenated, alternate leaves, downy underneath; and from the sides and ends of the branches small white flowers in clusters; succeeded by small, roundish, purple fruit, like haws.

3. M. Canadensis, Canada snowy mespilus, has a shrubby, smooth stem, branching four or five feet high, with smooth, purplish branches; oval oblong, serrated, smooth leaves, on long foot-stalks; and all the branches terminated by snowy white clusters of flowers, succeeded by small purplish fruit like haws.

4. M. chamæ-mespilus, the dwarf medlar, or bastard quince, has a shrubby, slender, smooth stem, branching weakly four or five feet high, having purplish branches; oval, serrated, smooth leaves on long foot-stalks; and from the axillas purple flowers, collected into round heads, with narrow, purplish, deciduous, bracteæ; succeeded by small red fruit.

5. M. cotoneaster, the dwarf quince, rises with a shrubby, smooth stem, branching four or five feet high; the branches slender and reddish; oval entire leaves, on short foot-stalks; and from the axillas, small close-sitting purple flowers, two or three together; succeeded by small, roundish, bright red fruit.

6. M. Germanica, German mespilus, or common medlar, rises with a deformed tree stem, branching irregularly fifteen or twenty feet high; spear-shaped leaves, downy underneath; and large, close-sitting, white flowers, singly from the sides of the branches; succeeded by large roundish brown fruit, the size of middling apples, which ripen in October, but are not eatable till beginning to decay. The varieties are, common great German medlar, smaller Nottingham medlar, and spear-shaped Italian medlar. These all all cul

tivated in the English gardens for the fruit: the two former are the most common; but the latter, though smaller, is preferable for richness of flavor. These kinds are never eatable, until they begin to rot; for, when firm and sound, they are of a singularly austere disagreeable taste; yet having lain some time after being gathered, till they begin to assume a state of decay and become soft, they acquire a delicious flavor, extremely agreeable to many. They all ripen in the end of October, or beginning of November; when, being gathered, some should be laid in moist bran, in several layers, to forward their decay; others on straw in the fruitery; those in the bran will be ready for use in about a fortnight, and those laid on straw will come forward in succession.

7. M. pyracantha, the evergreen thorn, rises with a shrubby spinous stem, branching diffusely twelve or fourteen feet high, the branches slender and flexible, with a dark greenish bark, armed with long sharp spines; spear-shaped, oval, crenated, evergreen leaves; and all the shoots terminated by numerous clusters of whitish flowers; succeeded by large bunches of beautiful red berries, remaining all winter, and exhibiting a very ornamental appearance. All these seven species are of the tree and shrub kind; the first six are deciduous, the seventh an evergreen; the leaves are universally simple; those of the mespilus Germanica very large, the others mostly of moderate size, and which in most of the sorts grow upon short foot-stalks. They all flower abundantly every summer, the flowers universally hermaphrodite, and consisting each of five large roundish petals, twenty stamina, and five styles. They are all very hardy, succeed in any soil and situation, and their propagation and culture are very easy. The Germanica and its varieties are cultivated as fruit-trees, chiefly as standards, sometimes also as espaliers for variety. The other species are very proper furniture for any ornamental plantation, where they make an agreeable variety with their different foliage; and their flowers make a fine appearance, as also their fruit in autumn and winter, which, if not devoured by birds, remain long on the branches, and afford a fine variety in those seasons. The pyracantha, being rather of flexible growth, is most commonly trained against walls or fronts of houses, for the support of its flexible branches. When it is designed to have any of the common medlars as fruit-trees, they may be trained either as dwarfs, for dwarf standards, or for espaliers, or as half or full standards, and managed nearly as other fruit trees, particularly the apple and pear. They are raised either by seed, by grafting, or by budding; but the two latter methods are the most certain for continuing the sorts without variation.

MESPRISE'. Of Fr. *mesprise, mespris.* Contempt; scorn. Obsolete.

Mammon was much displeased, yet not he chose
But bear the rigour of his bold *mespise*,
And thence him forward led, him further to entice.
Spenser.

MESS, *n. s.* & *v. a.* } Saxon meꞅe; Goth.
MESS'MATE, *n. s.* } *mesa*; Fr. *messe*; Ital. *messo.* A dish; quantity of food eaten at table; the party or society meeting there: to mess is to eat or partake the food: messmate, a mate at mess or table.

The bounteous huswife Nature, on each bush
Lays her full *mess* before you.
Shakspeare. Timon of Athens.

Now your traveller,
He and his toothpick at my worship's *mess.*
Shakspeare.

Had either of the crimes been cooked to their palates they might have changed *messes.*
Decay of Piety.

Herbs and other country *messes*,
Which the neat-handed Phillis dresses.
Milton.

From him he next receives it thick or thin,
As pure a *mess* almost as it came in. *Pope.*

MES'SAGE, *n. s.* } Fr. *message, messager*;
MES'SENGER. } of Lat. *missus.* An errand; advice or intelligence sent: messenger one who carries a message or tidings.

She doth display
The gate with pearls and rubies richly dight,
Through which her words so wise do make their way,
To bear the *message* of her gentle spright. *Spenser.*

Came running in, much like a man dismaid,
A *messenger* with letters, which his *message* said.
Id.

May one, that is a herald, and a prince,
Do a fair *message* to his kingly ears?
Shakspeare.

She is fair, and fairer than that word,
Of wondrous virtues; sometimes from her eyes
I did receive fair speechless *messages.* *Id.*

Yon grey lines,
That fret the clouds, are *messengers* of day.
Id.

Evermore, when God's *messengers* are abandoned destruction is near. *Bp. Hall.*

The earl dispatched *messengers* one after another to the king, with an account of what he heard and believed he saw, and yet thought not fit to stay for an answer. *Clarendon.*

Gently hast thou told
Thy *message*, which might else in telling wound,
And in performing end us. *Milton's Paradise Lost.*

The welcome *message* made, was soon received;
'Twas to be wished and hoped, but scarce believed.
Dryden.

Let the minister be low, his interest inconsiderable, the world will suffer for his sake; the *message* will still find reception according to the dignity of the *messenger.* *South.*

Joy touched the *messenger* of heaven; he stayed
Entranced, and all the blissful haunt surveyed.
Pope.

MESSALINA (Valeria), a daughter of Messala Barbatus. She married the emperor Claudius, and disgraced herself by her cruelties and incontinence. Her husband's palace was not the only seat of her lasciviousness, but she prostituted herself in the public streets, and few men there were at Rome who could not boast of having enjoyed the favors of the impure Messalina. Her extravagances at last irritated her husband, who commanded her to appear and answer all the accusations which were brought against her; upon which she attempted to destroy herself; and, when her courage failed, one of the tribunes

who had been sent to her despatched her with his sword. Juvenal says of her,

Et lassata viris necdum satiata, recessit.

MESSANA, in ancient geography, the first town of Sicily on crossing over from Italy, situated on the strait now called the Faro (Italicus); anciently called Zancle, according to Diodorus Siculus, from king Zanclus; or, as others say, from the Sicilian word zanclon, a sickle, from the curvity of the coast: and hence zanclæi, the people.—Herodotus, Pausanias. Messana is derived from the Messenii of Peloponnesus.—Strabo. Thucydides ascribes its origin to Anaxilus, the Messenian, tyrant of Rhegium, who received all comers, calling the town after the name of his country. The Greeks always called it Messene; the Romans Messena constantly, to distinguish it from Messene of Peloponnesus. It is now called Messina.

MESSENA, or MESSENE, an inland town, and the capital of Messenia, a country of Peloponnesus; erroneously placed by Ptolemy on the coast. It was built by Epaminondas, who recalled all the Messenian exiles, and gave the town the name of Messene. It vied, in point of strength and situation, with Corinth, according to Strabo; and therefore Demetrius Phalereus advised Philip II. that, if he wished to have Peloponnesus in his power, he should make himself master of these two towns, as thus he would have the ox by both horns.

MESSENGERS are certain officers chiefly employed under the direction of the secretaries of state, and always in readiness to be sent with all kinds of despatches, foreign and domestic. They also, by virtue of the secretary's warrant, take up persons for high treason, or other offences against the state. The prisoners they apprehend are usually kept at their own houses, for each of which they are allowed 6*s.* 8*d.* a-day by government: and, when they are sent abroad, they have a stated allowance for their journey, part of which money is advanced for the expense of their journey. They have also a standing salary.

MESSENIA, a country in the south of Peloponnesus, mostly maritime, situated between Elea on the west, and Laconica to the east. Anciently a part of Laconica under Menelaus, and called Messene by Homer; interpreted by the scholiast Messenæa Regia. This country is famous in history, on account of the resistance made by the Messenians to the Spartans, and the exploits of their hero, Aristomenes. The first hostilities commenced about A. A. C. 652. Though inferior in the knowledge of the art of war to the Spartans, yet, by keeping for some time on the defensive, they so much improved themselves, that in three years they were able to give battle to their enemies in the open field; nor did they appear to be in any degree inferior either in courage or conduct; the war was therefore continued, with various success on both sides. At last both consulted the oracle at Delphi; and received for answer, 'that whoever should first dedicate 100 tripods in the temple of Jupiter at Ithome, a strong hold of the Messenians, should be masters of the country.' The inhabitants of Messenia, on hearing this, having no money to make the tripods of brass, began to cut them in wood; but before this could be accomplished, a Spartan, having entered into the city by stratagem, dedicated 100 little tripods of clay: on which the Messenians submitted to the Spartans. But they were treated with so much barbarity by these tyrants, that a new war commenced under Aristomenes, a man of invincible valor, and enthusiastically fond of liberty. He perceived that the Argives and Arcadians, who acted as allies of the Lacedæmonians, adhered to them only through fear, and in reality hated them, and wished to revenge the injuries they had done them. To these Aristomenes applied; and, receiving an answer conformable to his wishes, he engaged his countrymen unanimously to take up arms. About a year after, and before either party had received any auxiliaries, the Spartans and Messenians met at the village Deræ, where an obstinate engagement ensued. Aristomenes in this contest so distinguished himself, that his countrymen unanimously saluted him king; which title he, however, waived, alleging that he took up arms to set them free, and not to make himself great: he however accepted the title of general, with a power of doing whatsoever he thought requisite for the service of the public. As it now appeared that this war would be long and bloody, the Spartans again sent to enquire of the oracle concerning its event: the answer was, That it behoved the Spartans to seek a leader from Athens. The Athenians, naturally envious of the Spartans, granted their request, but in such a manner as manifested their hatred; for they sent them for a general Tyrtæus, a schoolmaster and poet, and lame of one foot. Meantime, Aristomenes had drawn together a large army; the Eleans, Argives, Sicyonians, and Arcadians, having sent troops to his assistance; the Spartans having no ally but Corinth. The Spartan kings, however, offered the enemy battle, which Aristomenes readily accepted. It was obstinate and bloody, but the Messenians were victorious, and the Spartans put to flight with great slaughter. Tyrtæus now convinced them that he was capable of fulfilling the promises made by the oracle; he encouraged them by his poems, directed them by his counsels, and recruited their broken armies from among the Helotes. Aristomenes, on the other hand, acted with no less prudence and vigor. He led out the Messenians, to act offensively against their enemies; and, entering Laconia, took and plundered Pharæ, putting all who resisted to the sword, and carrying off an immense booty. The Spartans sent immediately a body of forces to overtake the Messenians, but Aristomenes routed these pursuers, and continued to slaughter them, till he was disabled by a wound in his side, which occasioned his being carried out of the battle. His cure being finished, he resolved to carry the war to the gates of Sparta; but, whether he found his design impracticable, or was influenced by some dream, he gave out that Castor, Pollux, and Helena, had appeared to him, and commanded him to desist. Soon after this, going with a small party to make an excursion, and attempting to seize some women who were celebrating religious

rites near Egila, a village in Laconia, those zealous matrons fell upon him and his soldiers with such fury, that they put them to flight, and took him prisoner; but he soon after escaped, and rejoined his forces. In the third year of the war, the Spartans with a great force entered Messenia, whither Aristocrates king of Arcadia was come, with a great body of troops, to their assistance; but the Spartans bribed him to betray his confederates. When the battle began, the deceitful Arcadian represented to the forces under his command the danger they were in, and the great difficulty there would be of retreating into their own country, in case the battle should be lost: he then pretended that the sacrifices were ominous; and, having thus terrified the Arcadians, he not only drew them off from both wings, but in his flight forced through the Messenian ranks, and put them also in confusion. Aristomenes and his troops defended themselves the best way they could; but the Spartans surrounded them on all sides; so that most of their army and chief nobility were cut to pieces. Aristomenes, with the remains of his shattered forces, retired, and, perceiving that it was now impossible to maintain the war against the Lacedæmonians upon equal terms, he advised his countrymen to fortify mount Era, and to make the best dispositions possible for a long defence. He likewise placed garrisons in Pylus and Methone on the coasts; and to these three places he gathered all the inhabitants, leaving the rest of Messenia to the mercy of the Spartans. They, considering the war as now finished, divided the lands among their citizens, and caused them to be carefully cultivated, while they besieged Era. But Aristomenes quickly convinced them that the war was far from being over: he chose out 300 men, with whom he ravaged all the adjacent country; carried off a prodigious booty; and, when Messenia could no longer supply the wants of his garrison, penetrated into Laconia, and bore away corn, wine, cattle, &c., for the subsistence of his countrymen in Era; so that at last the Spartans issued a proclamation, forbidding the cultivation, not only of the Messenian territory, but also of Laconia in its vicinity; whereby they distressed themselves more than their enemies, inducing at last a famine in Sparta, with its usual attendant, sedition. Here the wisdom of Tyrtæus again supported the Spartan courage; and influenced them to continue the blockade of Era, and maintain a flying camp for the security of the country. Aristomenes, however, still committed terrible depredations with his small corps of 300 men. Among other places which he plundered was the city of Amyclæ; whence he carried off a great quantity of riches, and many carriages laden with provisions. The Spartan kings, as soon as they heard of this expedition, marched after Aristomenes, and, as the Messenians were encumbered with their booty, came up with them before they could reach Era. In this situation, Aristomenes, prompted rather by despair than prudence, made a long and vigorous resistance against the whole Lacedæmonian army. At length, however, numbers prevailed; the greatest part of the Messenians were slain on the spot; and Aristomenes, with about fifty of his men who survived, were taken prisoners; that chief having received so many wounds that he was senseless when they carried him away. The Lacedæmonians expressed the utmost joy at the sight of this illustrious captive; who, for so many years, by his single abilities, had enabled his exhausted country to defend itself against the whole force of Sparta. When he was recovered of his wounds, they barbarously decreed him and all his fellow-prisoners, to be thrown into a deep cavern, the common punishment of the lowest offenders. Three days he continued in this dismal place, lying upon, and covered with, dead bodies. The third day he was not only almost famished, but nearly suffocated with the stench of corrupted carcases, when he heard a fox gnawing a body near him. Upon this, perceiving the fox just by him, he, with one hand, seized one of its hind legs, and, with the other, defended his face, by catching hold of its jaw when it attempted to bite him. Following as well as he could his struggling guide, the fox at last thrust his head into a small hole, and soon forced his way through, and opened a passage to the welcome rays of light. Feeble as he was, Aristomenes wrought an outlet with his nails; and, travelling by night with all possible expedition, at length arrived safe at Era, to the great joy and amazement of his countrymen. His escape was at first hardly credited; but he soon put the truth of it beyond all doubt, by falling on the posts of the Corinthians, who had a considerable body of troops before Era. Most of their officers, with a multitude of private men, he slew, and pillaged their camp; and, in short, did so much mischief, that the Spartans, under the pretence of an approaching festival, agreed to a cessation of arms for forty days, that they might have time to bury their dead. On this occasion Aristomenes, for the second time, celebrated the hecatomphonia, or the sacrifice appointed for those who had killed 100 of the enemy with their own hands. He had performed the same before and after his second battle; and he lived to do it a third time. But, notwithstanding this truce, certain Cretan archers, in the service of the Spartans, seized Aristomenes as he was walking without the walls, and carried him away a prisoner. There were nine of them in all; two of them immediately flew with the news to Sparta, and seven remained to guard their prize, whom they bound, and conducted to a cottage inhabited only by a widow and her daughter. The young woman had dreamed the night before, that she saw a lion without claws, bound, and dragged along by wolves; and that she having loosed his bonds, and given him claws, he immediately tore the wolves to pieces. As soon as Aristomenes came into the cottage, and her mother, who knew him, told her who he was, she instantly concluded that her dream was fulfilled; and therefore plied the Cretans with drink; and, when they were asleep, took a poniard from one of them, cut the thongs with which Aristomenes was bound, and then put it into his hands. He presently verified her vision, by putting all her guards to death; and then carried her and his mother to Era, where, as a reward for her service, he married the young woman to his son Gorgus,

then about eighteen years of age. When Era had held out nearly eleven years, it fell into the hands of the Spartans by an accident; the servant of one Empiramus, a Spartan commander, driving his master's cattle to drink at the river Neda, met frequently with the wife of a Messenian, with whom he had an amour; and by means of whose husband he learned, that, Aristomenes being detained in his bed by a wound, the soldiers, knowing that he could not walk the rounds, had a grant to retire to their houses, to avoid the inclemency of the season. The Spartan no sooner heard this, than he hastened away to carry the news to his master. The kings were then absent from the camp, and Empiramus had the chief command of the army. As soon as he received this information, he ordered his army to begin its march, though it rained excessively, and there was no moon-light. They seized all the Messenian posts, and, as soon as it was light, the attack began; and Era had been quickly taken, if only the men had defended it; but the women fought with such fury, as made the event doubtful. Three days and two nights this desperate engagement lasted; at last, all hopes of preserving the city being lost, Aristomenes drew off his wearied troops. Early the fourth morning, he disposed the women and children in the centre, the Messenian youth in the front and rear, the less able men in the main body; himself commanded the van; the rear-guard was brought up by Gorgus, and Manticlus, the son of Theocles, a Messenian of great merit, who fell with much glory in this attack. Aristomenes then caused the last barrier to be thrown open, and began to march directly towards the Spartan troops, to force a passage. Empiramus, perceiving his intent, ordered his men to open to the right and left, and give them a passage; so that Aristomenes marched off in triumph to Arcadia. The Arcadians, when they heard that Era was taken, were very anxious to assist their old allies, and entreated their king Aristocrates to lead them into Messenia. But he, corrupted by the Spartans, persuaded them that it was too late; that the Messenians were all cut off; and that such a step would only expose them to the fury of the conquerors. However, hearing that Aristomenes was on the frontiers of Arcadia, they went in crowds to carry him provisions, and to testify their readiness to afford him and his troops all possible assistance. Aristomenes desired to be heard before a general assembly; which being convoked, he proposed one of the boldest schemes recorded in history; he said, that he had yet 500 undaunted soldiers, who, at his command, would undertake any thing; that it was probable most of the Spartans were employed in pillaging Era, and that therefore he determined to march and surprise Sparta; which appeared so plausible, that all the assembly commended his unshaken courage. Aristocrates, however, by various pretences, retarded the execution of the project. The Arcadians, who began to suspect him, surprised the messengers as they came back, seized the letters, and read them openly in the assembly. The purport of them was, that the Spartans acknowledged his great kindness, and promised that they would be grateful. Upon this the Arcadians stoned the king while Aristomenes stood with his eyes fixed on the ground, and shed tears to see him so deservedly put to death. The Arcadians afterwards erected a monument to perpetuate his infamy. The Messenians under Gorgus and Manticlus passed over into Sicily; where they founded the city of Messene. Aristomenes remained, however, in Greece, where he married all his daughters, except the youngest, to persons of rank. A prince of Rhodes, enquiring of the oracle at Delphi whom he should espouse, that his subjects might be happy under his posterity, was directed to marry the daughter of the most worthy of the Greeks. He therefore demanded and received the virgin daughter of Aristomenes, Aristomenes himself accompanying him back to his dominions, where he formed a scheme of uniting the Lydians and Medes against the Spartans, resolving with this view to go into Media, and to the court of Sardis; but meanwhile death surprised him, and thereby freed the Spartans from one of the most formidable enemies they ever had.

MESSI'AH, *n. s.* Heb. משיח, of משח, to anoint; Gr. *μεσσιας*. The Christ; the anointed Saviour of the world.

And after the end of the said four hundred and thirty-four years, from the restitution of the temple, shall the *Messiah* be slain, not for any cause that shall be found in him, but for the sins of men.

Bp. Hall.

Great and public opposition the magistrates made against Jesus, the man of Nazareth, when he appeared as the *Messiah*. *Watts.*

MESSIAH, Heb. משיח, signifies one anointed, or installed into an office by unction. It was usual among the Jews to anoint kings, high-priests, and sometimes prophets, at the designation or instalment of them, to signify emblematically the mental qualifications necessary for discharging these offices. Saul, David, Solomon, and Joash, kings of Judah, received the royal unction; Aaron and his sons received the sacerdotal; and Elisha, the disciple of Elijah, received the prophetic unction.—The name Messiah was given to the kings and high-priests of the Jews. The patriarchs and prophets are also called Messiahs, or the Lord's anointed. See 1 Sam. xii. 3, 5; 1 Chron. xvi. 22; Psalm, cv. 15. Thus this name Messiah was principally, and by way of eminence, given by the Jews to their expected great Deliverer; and is a name the Christians apply to Jesus Christ (χριστος) in whom the prophecies relating to the Messiah were accomplished. The sum of these prophecies is, That there should be a glorious person named Messiah, descended from Abraham, Isaac, and Jacob, who should be born at Bethlehem, of a virgin of the family of David, then in its decline, before the Jews ceased to be a people, while the second temple was standing, and about 500 years after Ezra's time; who, though appearing in mean circumstances, should be introduced by a remarkable forerunner, whose business it should be to awaken the attention and expectation of the people. That this illustrious person should himself be eminent for the piety, wisdom, and benevolence of his character, and the miraculous works he should perform; yet that, notwithstanding all this, he should be rejected and put to death by

the Jews: but should afterwards be raised from the dead, and exalted to a glorious throne, on which he should through all generations continue to rule, at the same time making intercession for sinners. That great calamities should be brought on the Jews for rejecting him; whereas the kingdom of God should by his means be erected among the Gentiles, and extended unto the ends of the earth; wherever it came destroying idolatry, and establishing true religion and righteousness. In a word, that this glorious person should be regarded, by all who believed in him, as a divine teacher, an atoning sacrifice, and a royal governor; by means of whom God would make a covenant with his people, very different from that made with Israel of old; in consequence of which they should be restored to, and established in, the divine favor, and fixed in a state of perpetual happiness. The Jews still wait for the coming of the Messiah, being infatuated with the notion of a temporal prince, who is to be a mighty conqueror, and to subdue all the world; a delusion in which we regret to see them encouraged by some modern Christian interpreters of prophecy. Many modern rabbies, according to Buxtorf, believe that the Messiah is already come, but that he keeps himself concealed, and will not manifest himself because of the sins of the Jews. Some of the Jews, however, to reconcile those prophecies that seem to contradict each other as to the character and condition of the Messiah, have had recourse to the hypothesis of two Messiahs, who are yet to succeed each other; one in a state of humiliation and suffering; the other of glory, splendor, and power. The first, they say, is to proceed from the tribe of Ephraim, who is to fight against Gog, and to be slain by Annillus. Zech. xii. 10. The second is to be of the tribe of Judah, and lineage of David, who is to conquer and kill Annillus, and restore the kingdom of Israel, reigning over it in the highest glory and felicity. Jesus Christ asserts himself to be the Messiah, in John iv. 25. Several impostors have endeavoured to pass for Messiahs, as Christ himself predicted. J. Lent, a Dutchman, has written a history De Pseudo-Messiis, Of False Messiahs. The first he mentions was one Barcochab, who appeared under Adrian. The last was rabbi Mordecai, who began to be talked of in 1682. A little before him, viz. in 1666, appeared Sabbathei Sebi, who was taken by the Turks, and became a Mahometan. The most valuable modern publication, on the subject of the Messiah whom the Old Testament teaches us to expect, is Dr. J. P. Smith's Scripture Testimony to the Messiah, 2 vols. 8vo.

MESSINA, a celebrated city in the north-east of Sicily, standing on a strait called the Faro di Messina. This separates Italy from Calabria, and is opposite to the city, only from two to three miles wide. The town runs parallel with it, forming an oblong of more than two miles in length, and from a quarter to half a mile in breadth The finest part is the Marina, a long line of buildings facing the harbour; for more than a mile it is connected with a broad quay. This noble range of buildings was begun by the government so long ago as 1622, and was intersected by nineteen openings, leading to the same number of small streets, each entered by a gate. All the buildings suffered much by the earthquake of 1783; but it has risen from its ruins, and is again a beautiful promenade. Several lofty and rugged mountains rise behind: the town forms a fine sweep along these eminences, and rises in gradation, so as to present almost every public edifice distinctly. The whiteness of the buildings forms a beautiful contrast to the dark green of the forests, while the lower grounds are strewed with cottages and villages. Nothing can exceed the coup d'œil of the whole about a mile at sea. Since the great convulsion in 1783 the town has been rebuilt with great regularity, and several of the streets have been widened. Next to the Marina, the principal streets are the Via Nuova and St. Ferdinand, decorated with fountains, statues, and other objects of interest. The inner part of the town, formerly dirty, is now much improved, and the pavement is of lava cut into flags. Two rapid streams from the mountains traverse the town, and are confined by stone walls to prevent their overflowing.

The public buildings consist of thirty fine convents for both sexes, a hospital, four seminaries of education, six asylums for the poor, and two Monti di Pieta, or loan banks. The convents are richly ornamented, and possess considerable revenues. Here are also four libraries; a noble public prison; and fifty great and small churches, among which are several beautiful buildings, containing a number of admired paintings. The cathedral has a fine Gothic front, and a granite pillar which supports the roof, taken from the ruins of the temple of Neptune. The royal palace, the senate-house, and the episcopal palace, are also buildings of note.

The harbour of Messina is said to be the finest in the Mediterranean; and consists of a bay, which has the city along its west shore; on the east is a tongue of land, the point of which turns inward, so as to form an inlet (a quarter of a mile across) sufficiently wide for the ingress of fleets, and narrow enough to protect the enclosed waters from the storms of the sea. The circumference of this harbour is from four to five miles; and its depth in general not less than forty fathoms. It is defended by a strong citadel. Of the Faro wine, not less than 10,000 pipes are said to be shipped here annually. Other exports are corn, oil, fruit, and the various productions of Sicily. Silk-worms have long been cultivated: and there are several extensive manufactures of silk in the city, which supply a large proportion of its exports to the Levant. The imports consist chiefly of colonial produce and British manufactures.

Messina is of great antiquity, having been known both to the Romans and Greeks, and is remarkable for its misfortunes. It has been at different times called Zancle, Mamertina, Messana, &c. Allured by the advantages of its situation, the Cumæans, a commercial and enterprising people, invaded the island, and drove the Siculi from this settlement; they were in their turn overpowered by a band of Samian adventurers, who made way for a colony of citizens of Messene, and under these masters it changed its name to Messana. Their government was of short duration; for, in A. A. C. 289, it was de-

stroyed by the Mamertines, a warlike unprincipled nation, inhabiting the south part of Brutium.

These soldiers being received into Messina on their return to Italy from Syracuse, where they had served as mercenaries in the army of Agathocles, massacred the inhabitants, and usurped their possessions. The city was now called Mamertina: and, to support themselves against the resentment of the Sicilian powers, the Mamertines implored the protection of the Romans, who, eager to extend their dominion beyond the limits of Italy, and jealous of the growing power of Carthage, assisted these assassins with a consular army. This step brought on the first Punic war. The Mamertines reaped no other fruit from the alliance, but a more honorable degree of slavery. Messina was, however, always distinguished by particular attention and favors from the senate; and, excepting a short period during the wars of the triumvirate, appears to have tasted all the sweets of Roman prosperity, with but little mixture of adversity. Its fate, in the ruin of the empire, was similar to that of the rest of Sicily. In 829 it fell into the hands of the Saracens, but obtained very honorable terms of capitulation; for half the city was left to the Christians, where they were to be governed by their own laws, and profess their own religion undisturbed. In the other resided the bey of one of the five provinces, into which the Arabian conquerors had divided the island. Notwithstanding this indulgence, Messina was the first to cast off the yoke in 1037, when George Maniaces landed an army of Greeks and Normans on the shore of the Faro. It afterwards held out against the whole Mussulman force, till the feeble state of a distracted empire shut out all hopes of assistance from Constantinople. This unfortunate city then opened its gates to the army of the caliph, and felt very severely the weight of his resentment; but it did not long groan under the yoke; for, in less than twenty years, Roger the Norman took it by surprise, and delivered it from Mahometan oppression.

During the crusades, Richard I. of England, and Philip Augustus of France, wintered here in their way to Palestine. The Messinese were particularly tardy in entering into the national conspiracy of 1282, but afterwards exceeded the rest of the insurgents in deeds of cruelty. This, and the importance of their situation, pointed them out as the first objects of Charles's vengeance. He invested their city very closely, and declared so openly his determination to refuse all terms whatever to the besieged, that they saw no hopes of safety but in an obstinate defence. Their courage, perseverance, and sufferings, were excessive; at length their strength and resources began to fail rapidly, and every circumstance seemed to denounce their speedy destruction, when Roger Lauria appeared off the harbour with the Arragonian fleet, forced the king to retire with precipitation across the straits, and in his sight defeated and destroyed his naval armament. Robert, grandson of Charles I., also made a fruitless attack; but in the disturbed reign of Frederick III. Messina was delivered up to Lewis king of Naples and his consort queen Joan, who entered it in triumph. In a few years it returned to its former possessors.

The year 1672 was remarkable for the revolt of the Messinese. They threw off the Spanish yoke, and swore allegiance to Louis XIV. of France. They were for some time vigorously assisted by the French; but before the Spaniards had gained the least advantage, to excite any hopes of recovering so valuable a possession. Louis found himself necessitated to desert his new subjects, and leave them to the mercy of their old incensed masters. The horror of being thus abandoned, and the chastisement inflicted by Spain, now broke their fierce spirit, and they were stunned with the remembrance and effects of this blow, when the plague in 1743 was introduced from the Levant, and swept away more than half the inhabitants. From this chain of calamities, the opulence, trade, and population of Messina, have never recovered.

In 1780 this city continued, for more than six months, to suffer from an earthquake. And again on the 5th of February, 1783, the air was heavy and calm; the sky obscured with thick clouds, and the atmosphere seemingly all in a flame. About half after twelve at noon, the earth began to shake, with a dreadful noise. The shocks continually increased, and became at length so violent as to open the ground, and to overturn in two or three minutes a considerable part of the buildings. A long white cloud appeared to the north-west, and soon after another, very dark, in the same quarter. The latter in a moment spread over the whole horizon, and deluged the city with rain and hail, accompanied with dreadful claps of thunder. The inhabitants fled in the utmost terror to the fields and ships. From mid-day till five P. M., the earthquake continued almost without interruption. The shocks then became less frequent. The cries of the dying; the shrieks of those half-buried under the ruins; the wild terror with which others, who were still able, attempted to make their escape; the despair of fathers, mothers, and husbands, bereft of those who were dearest to them; formed altogether such a scene of horror as seldom occurs in the history of the calamities of the human race. Amidst that awful scene, instances of the most heroic courage, and the most generous affection, were displayed. Mothers, regardless of their own safety, rushed into every danger to snatch their children from death. Conjugal and filial affection prompted deeds not less desperate and heroic. But no sooner did the earthquake cease, than the poor wretches who had escaped began to feel the influence of very different passions. When they returned to visit the ruins, to seek out the situation of their fallen dwellings, to enquire into the fate of their families, to procure food, and collect some remains of their former fortunes—such as found their circumstances the most wretched became suddenly animated with rage and despair. Property was violated, and murder, rapine, and robbery, reigned among the ruins. About one A. M., another shock of the earthquake was felt, which overturned most of the remaining houses. Those whom want, or

avarice, or humanity, still detained among the ruins, now shared the same fate with those whom the former shocks had buried under them.

The succeeding day scarcely alleviated the distress of this dismal night: the few wretches who still survived found themselves destitute of every necessary. At length order was in some degree re-established; and in two days after every person was supplied at least with some small portion of necessaries. None yet, however, thought of returning to take up their abode among the ruins. The people fixed their residence on the plains of Porta Salvo, near Salleo. The nobles, magistrates, and merchants, took up their abode on another plain, on the other side of the stream Porta de Legno; the soldiers at Terra Nuova. Some violent shocks on the 7th of February and 28th of March completed the destruction of the city. The corn magazines, however, escaped without damage; and the public ovens and the aqueducts were little injured. The neighbouring villages, having suffered but little, were the first to relieve the remaining inhabitants. Maltese galleys for some days brought provisions to the poor and the sick, with a generosity which merits the highest praise. They also brought surgeons with medicines, &c., for the cure of the wounded. The money needed for the support of the people was taken from the treasury of Messina; for what the king of Naples sent was seized and spent by the garrison.

About 900 persons perished by this earthquake. The sea during the convulsion was slightly agitated in the harbour. Farther out the sea was more violently agitated; but none of the ships in the harbour were dashed to pieces. The waters rose so high as to be injurious in a very considerable degree to Faro, as well as along the coast of Scylla and Bagnara. This earthquake was not of a momentary duration, like that by which Lisbon was destroyed: for more than sixty days, from the 5th of February to the beginning of April, Messina continued to be shaken; and in that time felt more than 200 shocks. Even after that period the alarm was again and again renewed. Of the church of Purgatory, only the walls were left standing. One half of the steeple of the cathedral was beaten to the ground. The magazines of Porto Franco were likewise very much shattered. The fort of St. Salvator, being built on an artificial foundation, the side next the sea fell down; but on the other side, where it is founded on a rock, it stood unmoved by the shocks. On the 5th of February, when the earthquake was most violent, a strong smell of sulphur was felt. The earth was affected somewhat as if it had been borne upon a fluid, and seemed to reel like a ship tossed with the waves. This tremulous motion was felt all over Sicily. On the following days the sky was cloudy; the mountains of Sicily and the shores of Calabria continued covered with a thick fog like smoke. North and north-east winds raged with the most violent impetuosity. This disastrous year was scarcely ended, when the elements again renewed their fury to ravage this miserable land. On Tuesday the 6th of January, 1784, about sun-rise, the wind began to blow softly from the north-east. The sea gradually swelled, rose beyond its bed with rapid impetuosity, overflowed the quay, and lashed the ruins of the Palazzata. It loosened and displaced many of the stones of the mole, spread over the whole street, and attacked the pedestals of the statues which had been spared by the earthquake, and still stood firm among the ruins. The same furious wind, which swelled the sea in so extraordinary a manner, ravaged the whole coast from Messina to Syracuse.

After this last calamity the inhabitants were exempted from the payment of taxes, for a period of twenty-five years, and their harbour was declared a free port; that is, a port for the deposit of all goods, free of duty, until taken out for consumption. Messina had the advantage of being the head-quarters of the British forces for several years prior to the peace of 1814. Population 36,000. Fifty miles N. N. E. of Catania, and 130 east of Palermo.

MES'SUAGE, *n. s.* Law Lat. *messuagium*, from *mansio*. The house and grounds of an estate set apart for domestic use.

By the name of *messuage* may a garden, shop, mill, cottage, chamber, cellar, or the like, pass. In Scotland, *messuage* denotes what we call the manor-house, viz. the principal dwelling-house within the barony.
Dr. A. Rees.

MESURADO, a river of Western Africa, which rises in the mountains of Kong, and falls into the Atlantic, at the western extremity of the Grain Coast. On its banks is situated a kingdom of this name, the boundaries of which are uncertain. It is populous, and well cultivated, and contains excellent wood for ship-building. The capital is situated about eight miles up the river.

META, in the Roman circus, was a pile of stones of a pyramidical form, intended as a boundary of the stadium, or chariot-course. When the meta was passed the seventh time, the race was concluded. The greatest art and management were required in avoiding the meta, and yet going as near it as possible. If they went too near they were in the greatest danger of breaking the chariot to pieces; and, if they took too large a circuit in the turn, they gave their rivals an opportunity of getting within them, besides losing a great deal of ground. The boundary of the Grecian stadium, or course, was called τελος, τερμα, γραμμη, and αηρα γραμμη to which last name Horace probably alludes in calling death, ultima linea rerum. The metæ at Rome were first of wood, afterwards of stone but the emperor Claudius gilded them. In the Roman circus there were two metæ, one at the entrance of the course, and the other at the end of it. An egg was placed on the top of the meta.

META, a large river in New Grenada, Colombia, which has its rise in the mountains opposite Santa Fe de Bogota, and flows through the province of San Juan de los Llanos, and the district of Casanare. It receives many other large rivers; and, being swoln to an immense size, falls into the Orinoco, about 450 miles from its source, in long. 67° 45′ W., lat. 6° 10′ 30″ N. Before entering the Orinoco, it forms such a smooth body of water, that its current is scarcely perceptible.

Its banks are chiefly inhabited by very barbarous Indians. In the province of Juan de los Llanos, the missionary villages are numerous on its banks.

METAB'ASIS, *n. s.* In rhetoric, a figure by which the orator passes from one thing to another.

METACAR'PUS, *n. s.* } Gr. μετακάρπιον.
METACAR'PAL, *adj.* } In anatomy, a bone of the arm made up of four bones, joined to the fingers: belonging to the metacarpus.

It will facilitate the separation in the joints when you cut the finger from the *metacarpal* bone.
Sharp's Surgery.

The conjunction is called synarthrosis; as in the joining of the carpus to the *metacarpus.*
Wiseman's Surgery.

METAGITNION, the second month of the Athenian year, answering to the latter part of July and beginning of August; so called from the metagitnia, which was kept in it. The Bœotians called this month Panemus, and the Syracusans Carnius.

METAGRAM'MATISM, *n. s.* Gr. μετα, change, and γράμμα, a letter. A transposition of the letters of a name.

Anagrammatism, or *metagrammatism*, is a dissolution of its name into its letters, as its elements, and a new connexion of it by artificial transposition, without addition, subtraction, or change of any letter into different words, making some perfect sense applicable to the person named. *Camden.*

METAL', *n. s.*
METAL'LIC, *adj.*
METAL'LIFEROUS,
METAL'LINE,
METAL'LIST, *n. s.*
METAL'LOGRAPHY,
MET'ALLURGIST,
MET'ALLURGY.

Fr. Span. and Port. *metal*; Ital. *metello*; Lat. *metallum*; Gr. μεταλλον; Heb. מטל. A mineral substance; characterised in general by a peculiar lustre. See CHEMISTRY, part IV., and below; also written for METTLE, which see: metallic and metalline mean partaking or consisting of metal or its qualities: metalliferous, productive of metal: metallist and metallurgist, a worker, or a person skilled in metals; metallography, an account or description of metals: metallurgy, the art of converting or working them.

A king that would not feel his crown too heavy for him must wear it every day; but, if he think it too light, he knoweth not of what *metal* it is made.
Bacon.

Metalline waters have virtual cold in them; put therefore wood or clay into smith's water, and try whether it will not harden. *Id.*

The ancients observing in that material a kind of *metallical* nature, or fusibility, seem to have resolved it to nobler use; an art now utterly lost.
Wotton's Architecture.

The mind of man is of a strange *metal*: if it be not used, it rusteth; if used hardly, it breaketh: briefly, it is sooner dulled than satisfied, with a continual meditation. *Bp. Hall.*

Being glad to find their companions had so much *metal*, after a long debate the major part carried it.
Clarendon.

Both kinds of *metal* he prepared,
Either to give blows or to ward;
Courage and steel both of great force,
Prepared for better or for worse. *Hudibras.*

It is curious to observe how the nature of truth may be changed by the garb it wears; softened to the admonition of friendship, or soured into the severity of reproof; yet this severity may be useful to some tempers; it somewhat resembles a file, disagreeable in its operation, but hard *metal* may be the brighter for it. *Mackenzie.*

Though the quicksilver were brought to a very close and lovely *metalline* cylinder, not interrupted by interspersed bubbles, yet, having caused the air to be again drawn out of the receiver, several little bubbles disclosed themselves. *Boyle.*

Metallists use a kind of terrace in their vessels for fining *metals*, that the melted *metal* run not out.
Moxon.

The lofty lines abound with endless store
Of mineral treasure, and *metallic* ore.
Blackmore.

METAL, in heraldry. There are two metals used in heraldry, by way of colors, viz. gold and silver, in blazon called or and argent. In painting of arms these metals are represented by white and yellow, their natural colors. It is a general rule in heraldry never to place metal upon metal, nor color upon color: so that if the field be of one of the metals, the bearing must be of some color; and if the field be of any color, the bearing must be of one of the metals.

METALLURGY.

METALLURGY. This important branch of chemical science has been diligently cultivated both in the north of Europe and America. The abundance of ore found in the mountainous districts of Great Britain has also induced commercial speculators to pay considerable attention to the subject; but still it must be admitted that, in a scientific point of view, we have done but little for this art.

The art of managing metallurgical processes, with skill and effect, is of the highest antiquity, though few of the metals offer themselves to our notice in a state calculated for domestic economy; and those, when they really occur, are found in small quantities and in few localities. It may be proper to add, that many of the ores have no appearances by which their metallic contents could be judged of. They differ, indeed, very materially in this respect: thus galena has much the appearance of the metal it contains; yellow copper has a metallic appearance, but not indicating the metal; tin and iron stone are exceedingly ponderous: whilst some ores and arseniates of copper have neither weight nor metallic lustre.

It has been ingeniously supposed by Mr. Muchet that iron might be accidentally produced in the operation of converting wood into charcoal. Tradition informs us that the discovery was owing to the accidental burning of a forest in Greece. Similar circumstances might, however, lead to the knowledge of other metals, particularly such as have ores easy of reduction, and which are often found near the surface of the earth, such as lead and tin.

In the fourth chapter of Genesis Tubalcain is mentioned as 'an instructor of every artificer in brass and iron.' Vallerius says that, as far as he knew, Pliny was the first who enumerated the seven metals; but they were certainly known long before his age, and were mentioned both by Homer and Moses. Indeed the former has several curious passages on the subject, while speaking of Vulcan, which describe his forges as urged by bellows, which must have been applied nearly in the same manner as we use them now.

Thus having said—the father of the fires
To the black labour of his forge retires;
Soon as he bid them blow the bellows turned
Their iron mouths, and where the furnace burned,
Resounding breathed; at once the blast expires,
And twenty forges catch at once the fires;
Just as the god directs, now loud, now low,
They raise a tempest, or they gently blow.
In hissing flames huge silver bars are rolled
And stubborn brass, and tin, and solid gold.
Before, deep fixed, the eternal anvils stand,
The ponderous hammer loads his better hand;
His left with tongs turns the vext metal round,
And thick strong strokes the doubling vaults rebound. *Homer. Iliad*, book xviii. line 537.

In the time of Abraham gold and silver were esteemed, as they are at present, precious metals (Gen. xxiii. 16. Gen. xiii. 2); and hence it is reasonable to conclude that Noah was able to instruct his descendants in the art of metallic ores. This art was afterwards lost among the various colonies which quitted the plains of Asia in search of settlements.

Virgil, in the eighth book of the Æneid, mentions the melting of steel in large furnaces as contrasted with others in which bellows were used. And commentators on these passages mention that the Latin name for steel (chalybs) was derived from that of a people in Spain, who were very expert in the working iron and its ores and mines.

We find some of the earliest specimens of weapons to be made of an alloy of copper with tin, which forms a metal almost as hard as steel, without, however, possessing the other valuable properties of the latter. There would be great probability in this being made before steel, and being applied to similar uses; but we are not without evidence on this head, as Hesiod expressly says, that in the early ages the arms and instruments of the primitive heroes were composed entirely of brass.

The Phœnicians, a people derived from the Canaanites, and whose existence, as a separate nation, ceased 600 or 700 years before Christ, were famous for many arts, such as weaving fine linen, making glass, and particularly are recorded as having extraordinary skill in working the metals. Their fame was high for taste, design, and ingenious invention, and their commerce so extended by their industry and knowledge, that their ships even reached this country, and visited Cornwall for the tin which they purchased there.

After the Phœnicians we find the arts which they possessed principally in the hands of the Egyptians, and that a considerable quantity of real chemical knowledge, which the possession of such arts would indicate, became mixed up, according to the custom of the country, with fable and hypothesis, and passed chiefly into the hands of their priests. This seems to have been the case even in the time of Pliny; it was, however, communicated probably to the Alexandrian Greeks among the famous mysteries of the time; and as the complicated economy of the Egyptian hierarchy declined, by the consequences of the Roman conquest and other causes, the knowledge of some of their arts became diffused into Europe, and with it the spirit that pervaded their philosophy. To this we may trace the study of alchemy, which has been called 'an art without art, the beginning of which is falsehood, the middle hard labor, and the end beggary.'

Such a summary condemnation ought not, however, perhaps to be passed on a pursuit, which at any rate has procured for after times much knowledge, merely because we, with superior information, can see the absurdity of many of its pretensions, or can detect the imposture of many of its professions. The principal object of the alchemists was to make gold and silver: they imagined a certain mysterious sympathy between the metals and the heavenly bodies of our solar system. The great intrinsic value of the principal metals naturally engaged a great portion of the attention of those who acquired chemical knowledge; and, finding in the pursuit of many experiments unlooked-for compounds and results, two dominant passions in the human mind were flattered—the love of scientific discovery, and the desire of gain. The golden age of alchemy commenced with the conquests of Arabian fanaticism in Asia and Africa, and the subjection of Europe to superstition and the most profound ignorance. From the tenth to the thirteenth century little is known concerning the state of alchemical studies; but about the latter period Albertus Magnus, Roger Bacon, and Raymond Lully, who were able men, raised the pursuit to a degree of credit which it little merited; and it is spoken of as the Hermetic philosophy, and sometimes as the holy or divine art. The fifteenth century exhibited the same combination of chemistry with alchemy; but the language of the professors was less obscure, and the great authors were, during that period, Hollandus (Isaac and John), George Ripley, and Basil Valentine.

In 1550 appeared the celebrated treatise De Re Metallicâ, by Georgius Agricola; who, though bewildered in his youth by the false philosophy of the times, made ample amends by this admirable work on metallurgy and mineralogy. Alchemy now gave way to the increase of knowledge, and to the effect of the experimental mode of philosophising which was introduced by the great Bacon, though a certain number of impostors and some credulous and honest dupes continued at intervals to pursue the glittering phantom. The labors of some alchemists were excessive, and their patience almost beyond belief: experiments were continued for months, and even years, and their repetitions of digestions, sublimations, and distillations, were almost without end. They supposed that there might be two methods to make gold,—by synthesis or composition, and by transmutation. For the first they labored to find out the elements of the metals, which they imagined would be some metallic earth, and some essence or spirit which they chose to call sulphur. They held a won-

derful opinion of what might be discovered in mercury, which seemed to them likely to possess hidden qualties analogous to what they hoped to find from its volatility, and as they thought its spiritual nature.

Another set directed their efforts to the attempt at changing the baser metals into gold, and made their experiments mostly for this purpose on lead and copper, attracted, probably, by the weight of the one and the color of the other. To effect this transmutation they imagined that it was only necessary to discover the true elixir, or medicine of metals, the tincture, the powder of projection, or philosopher's stone,—for by such names were their preparations called,—which they imagined would purge away the impurities which only caused the differences between the inferior metals and the perfect ones.

In all this there may, perhaps, be less absurdity than has been urged; the discoveries of modern chemistry have been as wonderful, and might have seemed as improbable, in a former state of knowledge; nor can we be surprised when they observed, for instance, that lead almost always contains a certain portion of silver, and that all metals were capable of improvement by refining processes, that such expectations were excited. At any rate it is admitted that, from the labors of many of these men, great progress was made in chemical research which was useful in many respects, and particularly enlarged the skill and experience of the metallurgists, as may be seen in the instance of Agricola.

Another class of alchemists directed their labors to find an elixir of life, by which all disease was to be removed from the human frame, and existence prolonged to an indefinite period; but this subject only merits notice here as it is connected with the introduction of metallic preparations into medicine, which is another benefit we have derived from these absurd speculations. Paracelsus and Van Helmont were the great authors of this branch of the art.

The following are such of the metals as are usually seen in their metallic state in the popular sense of the word; and those principally will be treated of which form the material of most of our metallurgic processes:—

1. Unalterable by fire, or not oxidable by heat; a property which formerly was supposed to characterise a perfect metal:
   - Gold, silver, platina, nickel palladium . . . } fusible and malleable.
   - Rhodium, iridium . . } granular and brittle.
2. Oxidable by heat; and, being thus converted into what was called a calx, formerly considered as imperfect:
   - Mercury, copper, iron, tin, lead, zinc, . . } malleable.
   - Bismuth, antimony, cobalt, manganese, tellurium, titanium, tantalium, . } brittle but fusible.
   - Uranium, osmium, . } infusible and granular.
3. Metals which are acidifiable:
   - Columbium, chrome, tungsten, molybdena, . } fixed.
   - Arsenic, . . . volatile.

One of the most remarkable characters of metallic substances is the peculiar lustre which their polished surfaces exhibit; and which, from its being eminently characteristic of these substances, has been called the metallic lustre. The next remarkable property of metals is their opacity, which, though very considerable, is by no means absolute as has been affirmed. Leaf gold will transmit a green light, and silver leaf a white light. Probably other metals would also be somewhat transparent if equally attenuated. In specific gravity the metals exceed all other known substances. Sulphate of barytes, the heaviest of earthy bodies, is less than four and a half times as heavy as water. The lightest metal (if we except sodium and potassium), is more than six times as heavy as water, and the heaviest (platina) is nearly twenty-three times as heavy.

The principal metals, arranged according to their specific gravities, stand as follows:—

1.	Platinum	21·00
2.	Gold	19·30
3.	Tungsten	17·50
4.	Mercury	13·50
5.	Palladium	11·50
6.	Lead	11·35
7.	Silver	10·50
8.	Bismuth	9·80
9.	Uranium	9·00
10.	Copper	8·90
11.	Arsenic	8·35
12.	Nickel	8·25
13.	Cobalt	8·00
14.	Iron	7·78
15.	Molybdenum	7·40
16.	Tin	7·30
17.	Zinc	7·00
18.	Manganese	6·85
19.	Antimony	6·70
20.	Tellurium	6·10
21.	Sodium	0·972
22.	Potassium	0·865

The fusibility of metals is a property that eminently contributes to their usefulness; for without this it would be impossible to separate them from the earths and other impurities with which they are naturally mixed; not to mention the vast advantage of producing useful forms by the simple operation of casting into moulds of any required shape. The range of temperature at which various metals become fluid extends from the highest degree that our furnaces can produce, to a degree of cold, hardly ever occurring naturally. Thus, platina is scarcely fusible in the greatest furnace heat; iron and some others require an intense white heat; gold, silver, and copper, a bright red or low white heat; antimony a low red heat; and tin, bismuth, lead, and zinc, melt from about 450° Fahrenheit, to a temperature just under a red heat; while mercury is fluid, unless it be in a state of cold equal to about 40° below zero.

At certain heats several of the metals may be volatilised, or driven off in the state of vapor, and it is not improbable that all may be so, if we could raise the temperature high enough. But a considerable difference exists in this respect; and advantage is taken of it in many processes of smelting and refining, of thereby

separating the one metal from the other; those which are called fixed metals remaining in the state of strong ignition without evaporation, and those which are called volatile rising in dense fumes. Mercury, arsenic, antimony, and zinc, are highly volatile. Lead, tin, and bismuth, are less so, but are evaporated in a strong fire; while gold, silver, copper, and iron, are not sublimed by any heat which we usually employ.

The next striking and valuable property is their extensibility. This by the ancients was reckoned one of the essential characters of metallic bodies, but has ceased to continue so in consequence of the discovery of a number of metals destitute of this quality. Its high importance, however, may be well judged of, by observing that, for almost all mechanical purposes, the intrinsic value of metals is intimately dependent on their extensibility. This property may be classed under two heads,—malleability and ductility: that is to say, metals may either be extended by hammering, when they are said to be malleable, or by lamellating when they are said to be ductile. The metal of the greatest malleability is gold, which may be beaten into leaves so thin that they will float in the air like a feather. Silver may be reduced to nearly the same state of tenuity. Gold leaf is estimated at a thickness of little more than $\frac{1}{300000}$th of an inch. Silver leaf is about $\frac{1}{160000}$th. After these may be ranked in the following order copper, tin, lead, iron, and zinc; this last, however, to be made perfectly malleable, must be made somewhat hotter than boiling water. The other malleable metals are platina, palladium, nickel, and mercury.

It might at first sight appear that the ductility of metals would follow the same order as their malleability, both properties being merely a mode of extension; but it is evident that the ductility of a substance is compounded of its malleability and tenacity. Hence iron, though by no means so malleable as tin or lead, greatly surpasses them in ductility. The tenacity of metal is estimated by the weight that will be required to break a wire of a given diameter. Thus it is stated that a wire of one-tenth of an inch diameter of

Iron will bear, before it breaks,	705 lbs.
Copper	387
Platina	351
Silver	239
Gold	191

The tenacity of tin is greatly inferior to that of gold, and the tenacity of lead is the least of all.

Metals, besides the properties described, have of course others common to matter in general, or to bodies differently constituted in other respects; and some on which depend both the uses we make of them, and the operations for making them useful. The most important are those of divisibility and penetrability, elasticity, affinity for each other, and affinity for other substances. By the first affinity they unite together, forming mixed metals, called alloys or amalgams. By the second they combine chemically with various substances which alter their character, and form ores, salts, oxides, carbonates, hydrates, glasses, or enamels.

From the properties of the metals we are naturally led to consider their uses, and the means by which they are converted into the various forms that contribute so largely to the useful and ornamental arts of life. In any state of society, however rude, we can hardly conceive of substances more desirable than the metals; and thus we see that among savage nations nothing is more coveted, and that a few nails will be exchanged for their most highly prized articles; while, in the history of the civilised world, we may observe that metallurgic processes were greatly esteemed and eagerly pursued, and proficients in the art by which the metals were worked were honored for their knowledge and enriched by their skill. The metals will appear, upon the slightest consideration of the subject, to form a principal ingredient in most operations conducive to our comfort, amusement, or improvement. Without them we can conceive of no fit instrument of agriculture, art, or scientific research. Their uses may be said to be both active and passive; for, while they furnish us almost entirely with the tools by which substances of every kind are moulded to their destined form, they are likewise in themselves a principal material to be worked upon. The copper plate which receives the most delicate forms that the engraver can portray, takes its impression from the hard and pointed steel. The various properties, then, which peculiarly render the metals applicable to so many purposes are (as before stated), peculiar lustre, opacity, specific gravity, fusibility, extensibility (including malleability and ductility), tenacity. Also those properties which they possess in common with other substances; such as divisibility and penetrability, elasticity, affinity for each other, and affinity for other substances.

1. From the first of these properties, the metallic lustre, and the susceptibility of polish, results not only all the brilliancy which delights the eye under so many varying forms and circumstances, but also the perfection of mirrors and of the specula which have so much improved our telescopes.

2. The specific gravity of the metals is attendant upon that solidity and strength which forms a very prominent quality in fitting them for many important uses. The density which thus belongs to them enables us to employ them for vessels which are to retain or conduct the most subtile vapors, such as steam and the gases; and, as it is combined with ductility, to confine and employ them in the full energy of highly expansive force.

3. The third property of the metals, fusibility, gives rise to the art of founding, by which forms are produced in endless succession, similar to any given pattern, and similar to each other, and without the labor of working them into shape by long continued exertion. It is only necessary to mention the great use that is now made of cast iron and brass, as instances of the application of this property. As a part of the fusibility of metals, welding may be noticed, which is a quality that some of them have of

uniting into a solid state by a partial fusion of the surfaces; thus wrought iron is joined together, or iron is united to steel, which enables the workman to produce many most useful combinations.

4. Of all the properties, perhaps, extensibility is the most extraordinary; and it adapts the metals most for uses for which substitutes could hardly be found. The following processes depend upon this property.—Forging; which is applied to iron, steel, and copper. Laminating or rolling; by which plates or sheets of many metals are produced, and by varying the process we obtain rods and bars. Wire-drawing is applied to metals which have considerable tenacity, and is accomplished by pulling rods successively through holes, each smaller than the foregoing. Pipes are formed of soft metals, such as lead, tin, and copper, by a somewhat similar operation. Coining is an art also dependent on the ductility of metals, and seems to have been very anciently practised. A similar process applied to thin plates of metal is called stamping, by which many beautiful forms in plated goods and brass ornaments are produced. Plating, particularly of silver, upon copper or brass, is principally performed by applying the two metals to each other, and laminating them together, so that a perfect contact is produced. And gilt wire is formed by drawing a rod of silver which has been coated with gold, and by which the latter metal is attenuated to an almost incredible degree. The tenacity of metals makes them most suitable for many important purposes; such as chains, wires, steam-boilers, and other strong vessels, guns, &c.

5. By taking advantage of their penetrability, and their different degress of hardness, we avail ourselves of all the purposes which may be attained by the processes of turning, boring, filing, cutting or chipping, often called chasing, planing, engraving, polishing, and grinding.

6. The quality of elasticity, which many metals possess in a remarkable manner, gives us a great variety of our best springs for various important purposes; and under the same head we may arrange the use of metal for musical strings, or wires and bells.

7. From the affinity of the metals for each other we derive the power of making many compounds called alloys, and which either possess qualities intermediate between their constituents, or often differing from both; thus rendering it possible for us, if we do not find a metal suited to our purpose, to compound one adapted to particular uses. In noticing the principal alloys, it is to be observed, that gold and silver are hardened, so as to be more useful than they would be in their pure state, by the mixture of a little copper. Copper affords us many valuable alloys; as with zinc, brass; with tin, gun-metal, bell-metal, or bronze, and speculum metal; with tin and lead, pot-metal. Tin, alloyed with lead, forms the common solder used by plumbers; and also with a proportion of antimony and a small quantity of lead gives pewter. Lead and antimony form type metal, which has the requisite qualities of fusiblity and considerable hardness. Shot is made of lead mixed with a small quantity of arsenic. Iron is seldom alloyed with other metals, but steel has lately been mixed with minute portions of silver, platina, rhodium, &c., which are said to improve its quality. Bismuth (eight), lead (five), and tin (three), form an alloy so fusible as to melt in boiling water; though no one of these metals separately will melt under a temperature of 450°.

Amalgams are combinations of mercury with other metals, which in many instances readily take place even without the assistance of heat; the mercury producing in this case a kind of solution of the other metals. Use is made of this circumstance to separate gold and silver from the other substances with which they are mixed in the earth. Amalgams are employed for many purposes. That of gold is used in gilding; and silvering is performed in a similar manner in some instances. The amalgam of tin is used in silvering (as it is called) the backs of looking-glasses or mirrors. Another use made of the affinity of one metal for another is the coating applied to the surfaces by immersion. Thus the common tin-plates which are so much in use are made of sheet iron, dipped in melted tin, which, with proper treatment, combines with a portion of the iron and adheres to it. Copper for culinary vessels and many other purposes is tinned in nearly a similar manner.

Soldering is another instance of the use made of this affinity. It is performed by applying a metal, or an alloy, more fusible than the one the parts of which are to be united. The solder is easily melted without disturbing the form of the metal worked on; and, combining in some degree with it, makes a perfect joint.

Tin alloyed with lead makes a solder for lead and tin.—Zinc and a little copper, called spelter, makes a solder for copper and brass.—Brass makes a solder for iron.

8. From the affinity of the metals for other substances, and the ease with which they combine chemically with them, we derive a great number of substances most important to the arts, to medicine, and almost every purpose of life.

With oxygen the metals readily unite, and the metallic appearance and properties are lost, and a class of substances formed, which were at one time called calces, but are now more appropriately denominated oxides.

Iron with oxygen forms rust.

Lead with oxygen forms litharge, red-lead, and massicot.

Copper with oxygen forms scales and red oxide.

Mercury with oxygen forms substances which are important in medicine; such as precipitate per se, red precipitate.

Tin with oxygen forms enamel or glaze. Putty powder used in polishing. Black oxide is the ore.

Antimony with oxygen gives oxides used in medicine.

Arsenic with oxygen forms the poisonous state of this metal.

Manganese is principally useful from the large quantity of oxygen combined with it in its most common form. The metals very readily also unite with sulphur, and form many useful

compounds. Mercury gives a beautiful pigment called cinnabar or vermilion. Antimony gives some important medicines. Bismuth gives a cosmetic, pearl white, or blanc de fard. Carbon forms an important compound with iron in the article of steel; and plumbago is also a small proportion of iron with a large proportion of carbon.

The beautiful art of enamel-painting, with the colors given to our porcelain and glass, are to be referred to the combinations which take place between the metallic oxides and siliceous earth in a state of vitrification. Some of the oxides act powerfully as a flux in promoting the fusion of siliceous earth when it is converted into glass; and those of lead and arsenic (but particularly the former) are much employed in the manufacture of flint glass, and communicate no color to it. Other metallic oxides, however, combine this with silex, imparting to it a variety of delicate and transparent colors, which are used in the arts above mentioned.

Oxide of gold,	Fine purple.
Oxide of iron,	Common reds.
Oxide of silver, lead, and antimony,	Yellow.
Oxide of copper, chrome,	Green.
Oxide of cobalt.	Fine blue.
Oxide of manganese,	Violet.
Oxide of tin,	White.

The fabrication of imitative gems is dependent on the same circumstances, and the color of real gems may also be attributed to metallic mixtures.

Another numerous class of substances originating from the affinity of metals with other substances are the metallic salts, generally resulting from the combination of metals and acids. The list, if completely detailed, would extend to a great length. The following are some of those most commonly employed in the arts:—

Carbonates of lead,	White lead.
Carbonates of copper,	Verditer.
Sulphates of copper,	Roman vitriol.
Sulphates of iron,	Green vitriol, copperas.
Sulphates of zinc,	White vitriol.
Nitrates of silver,	Lunar caustic
Muriates of mercury,	Calomel and corrosive sublimate.
Muriates of tin,	Sal Jovis, used in solution in dyeing.
Acetates of copper,	Verdigris.
Acetates of iron,	Iron liquor.
Acetates of lead,	Sugar of lead.
Prussiates of iron,	Prussian blue.
Gallates of iron.	Ink, black dyes.

It has been shown that the metals readily combine with a variety of substances, and that in this state of combination they lose more or less of their metallic characters. In their natural state they are most usually thus combined, and the substances in union with them are called mineralizers. These consist of certain simple substances, some acids, water, and even some metals. Under these heads may be enumerated, as commonly occurring in natural combination with the metals

Oxygen.	Sulphuric acid.
Sulphur.	Muriatic acid.
Silex.	Phosphoric acid.
Carbonic acid.	Chromic acid.
Arsenic acid.	Molybdic acid.
Water.	Arsenic.

The result of the natural combination of these substances with metals, is called an ore.

Metallic ores are further compounded by including mixtures of more than one metal, as in the case of yellow copper ore, which contains both sulphuret of copper and of iron; galena, or sulphuret of lead, which commonly contains silver; and many ores which contain arsenic combined with other metals. Again, the metallic ores are much intermixed with earthy substances of various kinds, which, though not in chemical union, have often such an intimate mechanical union as to alter their character and add to the variety of their appearance, and to the difficulty of extraction of the pure metal.

Some of the compounds, which have been before described as the products of art, will appear again in the list of the ores; but generally speaking, owing to the circumstances of other admixtures, or their having been formed in modes which art cannot imitate, their external characters are different in the one case from what they are in the other. One peculiarity which will strike us is the variety of form and the splendor of their crystals, each assuming a regularity in their structure which forms an admirable guide by which their nature may be detected; and this circumstance has been used as the foundation of a study that has rendered the greatest services to mineralogy; it has assumed the name of crystallography, and should be attended to by all who intend to acquire a knowledge of the mineral kingdom. Besides the ores resulting from combinations such as have been mentioned, certain metals are found in their pure or malleable state, and we speak of them then as native metals, such are,

Platina, gold,	Almost always.
Silver mercury, copper, antimony,	Frequently.
Arsenic, tellurium, bismuth, iron,	Rarely.

Taking then into account these and the compounded state of the ores, it will appear that nature presents us with the metals under a great variety of form, exciting us to careful examination and diligent skill in their discovery, reduction, and adaptation to our wants. It will hereafter be shown that the art of reducing the metals depends upon our power of destroying these combinations, occasionally by presenting other affinities, but in all practical cases assisted by fire. The precipitation of copper, from solution by iron, affords an instance, however, of a metal being produced into its metallic state from its compound form without the aid of heat.

The metallic ores, as is well known, are not the produce of all countries, but are limited to situations in which are found certain rocks which enclose them, and which are therefore termed metalliferous rocks. These occur only in several parts of the world, and in these places only can we

expect a supply of the metals. England at present holds a distinguished place in the list of mining countries; our produce of iron, copper, lead, and tin, is greater than of any other country, and we also possess considerable quantities of zinc and manganese, with a proportion of others, such as arsenic, antimony, cobalt, and silver, and occasionally small quantities of gold.

The iron-works of Great Britain are of immense extent, and are to be found principally in Staffordshire, Shropshire, South Wales, Yorkshire, Derbyshire, North Wales, Durham, and some parts of Scotland. Copper is most abundantly produced in Cornwall and Devonshire; but certain quantities are also furnished from Anglesey, some parts of Ireland, and some from Staffordshire. Lead mines are abundant, and very productive on the borders of Northumberland, Cumberland, and Durham; next in value may now be placed those of Flintshire and Denbighshire. The lead-mines of Derbyshire were formerly very important, but are now much declined in value. Yorkshire has some productive tracts; and this metal is also found in Scotland, South Wales, Devonshire, and Cornwall. Tin is a very rare product, and but few parts of the world furnish it; in England it is quite confined to Cornwall and Devonshire, and it has there been worked from the earliest times, so as very probably to have been the first article of trade of our island, as we find the Phœnicians came here to purchase it. The ores of zinc are found in Somersetshire, Wales, Cornwall, and in other places, commonly with the ores of lead. Manganese is pretty abundant in the western parts of Devonshire and the adjacent parts of Cornwall. The quantity of silver raised in this country is certainly not very great; yet it is common in many of our lead ores, and is extracted in Cornwall, Northumberland, and Devonshire. It often exists, however, in a proportion that does not pay for separating it from the lead. The true silver ores are not common with us: however, they have been found in some instances, which are confined to Cornwall. The Herland mine, which was some time since worked, yielded some quantity; and in the eastern part of the county some regular silver veins are now working that produce ores similar to those of Peru or Mexico. Gold has been found in small quantities in Ireland, Cornwall, Scotland, and Devonshire; and arsenic, antimony, cobalt, and some other inferior metals, are found in the mines of Cornwall.

The other countries in the old world, which deserve notice for the metals they afford, are Germany, particularly Saxony and the Hartz Mountains, which have for many ages been the seat of mining, and have produced silver, lead, and a variety of other metals; Hungary which is rich in gold. Sweden and Finland have been long celebrated, and particularly for iron and copper mines, which formerly supplied a great part of the world, but now have much failed in their richness. The quality, however, of the Swedish iron and copper is still unrivalled. Siberia has been productive mines of the same metals. The rivers of Africa have long been known for the gold found in their sands, and many parts of Asia have yielded the precious metals as well as others. Spain was celebrated for its mines, and particularly of quicksilver or mercury and lead; and France has endeavoured to force its mines into notice, though almost too inconsiderable to deserve it In later times the great source of the precious metals has been the southern parts of America, and most of the enterprise of the adventurers to the new world may be attributed to the abundance of them which was soon found to exist there; and, from the time that Europeans gained footing, the quantity of gold from the Brasils, and of silver from Mexico and Peru, has been immense.

Experience has taught us, as has been observed, that metals are only to be found in sufficient quantity to repay the labor of procuring them in certain rocks, which are therefore called metalliferous. With respect to the general position of these rocks, as relating to each other and to those of a different order, it will be only necessary to state that the most important are, primitive rocks: granite, gneiss, mica, slate, clay slate. Secondary rocks: gritstone or sandstone, limestone, shale or plate.

Geologists indeed enumerate many others, but miners consider them as modifications of the same.

In this country clay slate is the most productive of the primitive class, and limestone of the secondary. The metallic ores are found occupying certain spaces in these rocks, which have been arranged under the names of veins, beds, and masses. The two first are the most usual.

Mineral veins are to be understood as fissures, which have been filled up by different mineral substances. Professor Brande very justly remarks that the term vein is objectionable, as it conveys the idea of a tube or pipe filled with metal; whereas it is a plate or lamina. They extend in nearly right lines, are of unequal thickness, penetrate to unknown depths, and usually are somewhat inclined from the perpendicular. They contain a great variety of metals differing in different countries, and in distinct veins in the same country.

English miners have different terms for veins: in Cornwall they are called lodes, in Derbyshire rakes, and the term dyke, sometimes used, describes the same thing. In these deposits the ores are accompanied by earthy substances generally in a a crystallised or sparry form, called vein-stones, matrix, gangue. Beds are the other kind of regular depository of metallic ores. These are flat or tabular masses interposed between strata of rock, and thus resemble beds of coal. They are seldom very thick; and mostly produce iron, manganese, and sometimes lead. Masses, or as they are sometimes called pipes, are irregular deposits of the metals, and, not being usual, need not occupy much of our notice. The metals or their ores are also sometimes found in alluvial soil, such as gravel and sand, in valleys, and particularly gold in a native form in many places, and tin ore in Cornwall and Banca. See MINERALOGY.

We may conjecture that the first rude process, by which metals were extracted from the ores, was that of putting a quantity of ore upon a

heap of wood, and setting the pile on fire, in conformity to the manner in which ores were smelted during the burning of forests; but as the force of the fire is greatly diminished by the dispersion of its flame, and as the air acts more forcibly in exciting fire when it rushes upon it with greater velocity, it is likely that the heap of wood and ore would soon be surrounded with a wall of stone, in which sufficient openings would be left for the entrance of the air, and thus a kind of furnace would be constructed.

The Peruvians, we are told, had discovered the art of smelting and refining silver, either by the simple application of fire, or, where the ore was more stubborn and impregnated with foreign substances, by placing it in small ovens or furnaces on high grounds, so artificially constructed, that the draught of air performed the function of a bellows, a machine with which they were totally unacquainted. This method of smelting ores on high grounds, without the assistance of a bellows, or at least of bellows moved by water, seems to have been formerly practised in other countries as well as in Peru. There are several places in Derbyshire, called boles by the inhabitants, where lead has been anciently smelted, before the invention of moving bellows by water; these boles were always situated upon high grounds, and mostly upon that side of a hill which faces the west, probably because the wind proceeds most frequently from that quarter. From a pig of lead, dug up in 1766 at one of these boles, near Matlock, and bearing an inscription in relievo, from which it appears to have been smelted in the age of Adrian, many of the boles in Derbyshire seem to be of high antiquity. However, this method of smelting ore by the variable action of the wind, being a very troublesome and precarious process, has been universally disused, and the more regular blast of a bellows has been introduced in its stead.

As the metals are generally intimately mixed and blended with earthy matter or spar, or often with other metallic matter of inferior value, before the processes of smelting or reduction by fire are resorted to, various mechanical operations are used to free them from such admixtures as much as possible, so that they may be rendered as pure as these means will allow before they go to the furnace.

The following is a brief account of the processes of *dressing*:—The ores, when first raised from the mines, are in various states; some in large masses from other matter, other large masses containing ores, spars, &c.; small pieces both of pure ore and that which is mixed, and much that is crumbled to small minute fragments.

The first operations relate to separating them into proper sizes and qualities by spulling or knocking, sifting or gridling, and picking. The purer parts are then separated, and are often removed at once for smelting after having been broken down to a certain degree of fineness or size. The other or mixed parts are submitted to various processes of washing, but first must be put into a proper state of division by being bruised and sifted to uniform sizes: this is done either by cobbing and bucking, manual operations; or by crushing and stamping by machines.

The processes of *washing* are very various, but depend on one general principle, that the metallic may be separated from the earthy parts by their different specific gravities. Thus, if both are agitated together in water, the heaviest will sink or be deposited first. This principle is applied by throwing the ores into streams of water, running over planes gently inclined. The ores settle at the upper, and the spar and earthy parts at the lower.

Another way much in use is by agitating the whole in sieves, so fine as to permit but little of the solid matter to pass, but to admit the water freely. By this agitation in water, the ore settles to the bottom of the sieve, and the spar or matrix floats at the top, where it is skimmed off and thrown away, and this is called jegging. When the ores are cleaned by dressing, they are fitted for the operations of reduction or smelting.

The following simple method of *smelting* is practised by the natives of the province of Mekran in Persia; which, although it may at times leave a trifling portion of the earth mixed with the metal, is, from its ingenuity, worthy of notice. When a sufficient quantity of the ore is collected, it is placed upon a pile of wood, which is set on fire, and constantly replenished with fresh fuel, until the ore melts and falls to the bottom, when it is separated from the ashes, and found to be considerably clearer than when first taken from the mine. It is then placed in a pit, made of earthern tiles, so constructed as to admit a fire under it. The ore is again melted in this pit, and a considerable quantity of the dirt and dross removed, by skimming the surface. After this process the metal is lifted out in a liquid state, poured into hollow cylinders of clay, and then sold.

To come to a complete understanding, relative to the processes of smelting, we must bear in mind the compound nature of these substances; observing, first, that all the ores are much mixed with earthy matter, even after the operation of dressing or washing, so that these earthy parts often bear a large proportion to the whole. Secondly, that volatile mineralisers, or substances which may be dissipated or evaporated by heat alone, enter in most cases into the composition of the ores. These, as has been mentioned, are sulphur, arsenic, carbonic acid, as the most common, and having therefore considerable influence on the processes. Thirdly, that other substances are found combined with the metals which cannot be evaporated simply, but may be separated by the addition of other bodies, to which they have greater chemical affinity. These are first and principally oxygen, and occasionally some acids. Lastly, that the metals being obtained, when the foregoing admixtures are got rid of, in a state of union one with the other, or at least to a certain extent, it must follow that, to have the one which we want in a pure state, the other should be separated or destroyed.

The processes which are employed for all these objects are, calcination or roasting; fusion or melting; refining, which is performed in se

veral modes. All these operations require the application of heat; and in most of them it is urged to a great degree of intensity.

The furnaces employed are of two classes. Blast furnaces, where the fire is excited by the use of bellows, or air cylinders constantly working; and air furnaces, where the effect is produced by strong draught, occasioned by the height or construction of the stacks of chimneys.

Blast furnaces are almost entirely employed in the reduction of the ores of iron, and are for that purpose constructed of large dimensions. Of a smaller size they are very commonly used in iron foundries, where pig-iron is simply melted for making various articles of cast-iron; and similar furnaces are in use in what are called the blowing-houses in Cornwall, for the finer kind of tin, called grain-tin. Blast furnaces of a small kind, called hearths, are much employed also in Cumberland and Yorkshire for melting lead ore; but they are nearly confined to this district, as the Derbyshire and Welsh smelters prefer air furnaces. The fuel mostly in use for the blast furnaces is coke, or coal charred so as to drive off its bituminous part; this is common for iron. In lead ores the principal fuel is peat or turf, with a small mixture of coal. And for tin ores they employ wood charcoal; coal would not answer, as it would cake together, and prevent the proper action of the furnace.

Air furnaces for smelting are of a construction which is usually called a reverberatory, though they have also some other local appellations. It is not unlike a large flat oven with the fire-place at one end, and the chimney at the other; so that the matter to be acted upon being placed in the bottom, between the flame playing over it, and reverberating upon it, produces the effect desired. These furnaces are used with a gentle draught and a moderate red heat for calcining or roasting, and with a stronger draught and an intense heat for fusion or flowing, and also for refining. They are the furnaces for copper ores, for lead ores in many places, and for the greater part of the tin ores. Common coal is the fuel used in them, and is the best adapted for them, as the strong flame it gives is just what is required, and the fire-places are so constructed that the fire can be stirred and supplied at pleasure.

The first operation which we shall notice, as it is the first in order in the large way, is that of *calcination* or *roasting*. The object here is to evaporate the volatile substances, or such as may be driven off by heat, or converted into a gaseous or aëriform state. These are most commonly sulphur or arsenic, and occasionally some acids.

In the roasting of ores, the following attentions must be given:—1. To reduce the mineral previously into small lumps, that the surface may be increased; but they must not be so small, nor placed so compactly, as to prevent the passage of the air and flame. 2. The larger pieces must be placed at the bottom of the pile, where the greatest heat is. 3. The heat must be gradually applied, that the sulphur may not be melted, which would greatly retard its expulsion; and that the spars, fluors, and stones, intermixed with the ore, may not crack, fly, and be dispersed. 4. The ores not thoroughly roasted by one operation must be exposed to a second. 5. The fire may be increased towards the end, that the noxious matters more strongly adhering may be expelled. 6. Fuel which yields much flame, as wood and fossil coals free from sulphur, is said to be preferable to charcoal or cokes. Sometimes cold water is thrown on the calcined ore, at the end of the operation, while the ore is yet hot, to render it more friable. No general rule can be given concerning the duration or degree of the fire, these being very various according to the difference of the ores. A roasting during a few hours or days is sufficient for many ores; while some, such as the ore of Rammelsberg, require that it should be continued during several months.

Schlutter enumerates five methods of roasting ores. 1. By constructing a pile of ores and fuel placed in alternate strata, in the open air, without any furnace. 2. By confining such a pile within walls, but without a roof. 3. By placing the pile under a roof, without lateral walls. 4. By placing the pile in a furnace consisting of walls and a roof. 5. By roasting the ore in a reverberatory furnace, in which it must be continually stirred with an iron rod.

The German process for extracting sulphur from pyrites may be thus described:—It ought, in the first instance, to be exposed to a heat sufficient to sublime the sulphur, or to make it distil in vessels, which must be close to prevent its burning. The furnaces employed for this operation are oblong, like vaulted galleries; and in the vaulted roofs are made several openings. These are called furnaces for extracting sulphur. In these furnaces are placed earthenware tubes, filled with pyrites broken into pieces of the size of small nuts. Each of these tubes contains about fifty pounds of pyrites. They are placed in the furnace almost horizontally, and have scarcely more than an inch of descent. The ends, which come out of the furnace five or six inches, become gradually narrower. Within each tube is fixed a piece of baked earth in form of a star, at the place where it begins to come narrower, in order to prevent the pyrites from falling out, or choking the mouth of the tube. To each tube is fitted a receiver, covered with a leaden pipe, pierced with a small hole to give air to the sulphur. The other end of the tube is exactly closed. A moderate fire is made with wood, and in eight hours the sulphur of the pyrites is found to have passed into the receivers. The residuum of the pyrites, after distillation, is drawn out at the large end, and fresh pyrites is put in its place. From this residuum, which is called burnings of sulphur, vitriol is extracted.

The eleven tubes, into which were put, at three several distillations, in all 900lbs. of pyrites, yield from 100lbs. to 150lbs. of crude sulphur, which is so impure as to require to be purified by a second distillation. This purification of crude sulphur is also done in a furnace in form of a gallery, in which five cucurbits are arranged on each side. These cucurbits are placed in a sloping direction, and contain about eight quintals and a half of crude sulphur. To them are

luted earthen tubes, so disposed as to answer the purpose of capitals. The nose of each of these tubes is inserted into an earthen pot, called the forerunner. This pot has three openings; namely, that which receives the nose of the tube; a second smaller hole, which is left open to give air; and a third in its lower part, which is stopped with a wooden peg.

When the preparations are made, a fire is lighted, about seven o'clock in the evening, and is a little abated when the sulphur begins to distil. At three o'clock in the morning the wooden pegs, which stop the lower holes of the forerunners, are for the first time drawn out, and the sulphur flows out of each of them into an earthen pot with two handles, placed below for its reception. In this distillation the fire must be moderately and prudently conducted; otherwise less sulphur will be obtained, and it would also be of a gray color, and not of the fine yellow which it ought to have when pure. The ordinary loss in the purification of eight quintals of crude sulphur is, at most, one quintal.

When all the sulphur has flowed out, and has cooled a little in the earthen pots, it is cast into moulds made of beech-tree, which have been previously dipped in water, and set to drain. As soon as the sulphur is cooled in the moulds, they are opened, and the cylinders of sulphur are taken out and put up in casks. These are called roll-brimstone.

There are some ores which contain so much sulphur that part of it is actually collected in the ordinary operation of roasting, without much trouble for that purpose. Such is the ore of Ramelsberg, in the country of Hartz. This ore, which is of lead, containing silver, is partly very pure, and partly mixed with cupreous pyrites and silver; hence it is necessary to roast it. The roasting is performed by laying alternate strata of ore and wood upon each other in an open field, taking care to diminish the size of the strata as they rise higher; so that the whole mass shall be a quadrangular pyramid truncated above, whose base is about thirty-one feet square. Below, some passages are left open, to give free entrance to the air; and the sides and top of the pyramid are covered over with small ore, to concentrate the heat and make it last longer. In the centre of this pyramid there is a channel which descends vertically from the top to the base. When all is properly arranged, ladles full of red-hot scoria, from the smelting furnace are thrown down the channel, by which means the shrubs and wood placed below for that purpose are kindled, and the fire is from them communicated to all the wood of the pile, which continues burning till the third day. At that time the sulphur of the mineral becomes capable of burning spontaneously, and of continuing the fire after the wood is consumed.

When this roasting has been continued fifteen days the mineral becomes greasy; that is, it is covered over with a kind of varnish; twenty or twenty-five holes or hollows are then made in the upper part of the pile, in which the sulphur is collected. From these cavities the sulphur is taken out thrice every day, and thrown into water. This sulphur is not pure, but crude; and is therefore sent to the manufacturers of sulphur to be purified in the manner above related.

The calcination of copper, lead, and tin ores, is performed in reverberatory furnaces at a moderate red heat. In the copper works in South Wales, each furnace contains full three tons of raw ores, which are frequently burned, to expose fresh surfaces, for twelve hours. Lead ores are treated in the same manner, in the same furnace often, which, with a higher heat, is used to melt them, and the charge seldom exceeds a ton. Tin ores being simple oxides, and not decomposable in this way, are roasted or calcined principally to alter the specific gravity of the pyrites with which they are mixed, which thus may be separated by subsequent dressing or washing. The furnaces for this purpose, in Cornwall, are called burning-houses. Iron ores, though commonly oxides, are often mixed with sulphurets or iron pyrites, and are roasted to free them from the sulphur; this, however, is not done in furnaces, but the ore is stratified with refuse coal, and burnt in large heaps in the open air.

At the Paris and Mona copper mines in the island of Anglesey, where the ores are poor in metal, but contain a large proportion of sulphur, they are treated in the same way, except that they do not find it necessary to use coal, as a small quantity of wood is sufficient to set the ore on fire, and combustion goes slowly on, owing to the sulphur; a heap of 300 or 400 tons is eight months in burning, and some of the sulphur is sublimed and is condensed in chambers or vaults, to which the flues are conducted.

In the process of calcination sulphur is generally inflamed, and, uniting with the oxygen of the atmosphere, is converted into sulphurous acid gas; which mixed, as it is, with the vapor of certain volatile metals, such as arsenic, zinc, antimony, or lead, forms a dense or suffocating smoke destructive of vegetation; but it does not appear so prejudicial to animal life, except where lead is prevalent. Whoever has seen the country round the copper works at Swansea, will have observed the desolating effect of the smoke; and yet it is proved, on the best evidence, that the men are not subject to any peculiar disease. One set of works there, belonging to Messrs. Vivians, who purchase the ores from the mines in Cornwall, sometimes work at the rate of 600 tons per week. These gentlemen have some time back constructed, at a great expense, erections to condense the noxious vapors, and upon which they have consulted Mr. Philips and other eminent chemists. They have altogether eighty-four reverberatory furnaces, of which twenty-five are used for calcining.

The ores being deprived of sulphur, or at least to a certain degree (for one calcination does not effect this completely), the next step in smelting is to get rid of all the earthy matter, which is done at once by the simple operation of bringing the whole into a state of *fusion*. It has already been stated that some of the metallic oxides combine with certain earths in fusion, and act powerfully as a flux, which is a term employed for substances that promote the fusibility of others in the fire. It is also necessary to remark, that although a single earth, as silex, for instance, is nearly in-

fusible by itself in our strongest fires; yet, by mixing the earths together, their infusibility is increased, and we obtain the power of rendering them all fluid by heat. Further, that some of the earths and some of the metallic oxides possess this influence in a greater degree than others. Thus lime, in all its states, but particularly in that of fluor-spar, and oxide of lead, are the most powerful assistants of the fusion of earthy matter in general, or the best fluxes. Many salts, indeed, possess this property to a much greater extent; but they are far too expensive for use in the larger operations of smelting, though they are much used for trials in the small way, called assays.

Now as the ores commonly contain different mixtures in different mines, and as it results from what has been said that such a combination as may be thus expected is useful in promoting the fusion of the whole, the smelters find it desirable to mix the ores from different veins on this account; but, as even this does not always succeed sufficiently, an addition is commonly made of lime, limestone, or fluor-spar. With a mixture of these the ores are submitted to the strongest action of the fire; complete fusion of the whole mass takes place; the earthy parts form a fluid impure glass, being completely vitrified; the metallic parts of the ore, either quite free from sulphur, or in a degree combined with it, are also entirely melted, and a perfect separation takes place; owing to the great difference in the specific gravity of the substances: the earthy glass in a liquid state, which is now called slag or scoria, occupying the upper place, and the metallic part by its weight sinking down and forming a liquid stratum of melted metal underneath, where also it is prevented from oxidation and evaporation from the intense heat applied. The whole is in some cases stirred, to assist the precipitation of the metallic matter to the bottom of the furnace; in other cases this is left to take place of itself.

The fusion of copper ore is conducted in reverberatory furnaces at a high degree of heat, and the slag is raked off in a fluid state. Lead and tin ores are treated in a nearly similar manner.

Iron smelting is carried on in blast furnaces of very large dimensions. in which coke is employed as fuel, and limestone is used as a flux. Copper of the first flowing is in part combined with sulphur, so as to require subsequent calcinations and repeated fusions before it comes to the refining process. Lead is generally produced pure in one operation from the reverberatory furnace, and also from the blast-furnace, where the sulphur is dissipated partly by the application of heat, and partly by combining with the lime which is used. Tin, being produced from an oxide, some carbonaceous matter, such as small-coal, is used in mixture with the ores, the carbon unites with the oxygen and leaves the metal pure, except as it may happen to be mixed with other metallic substances.

By the operations which have been described the whole metallic contents of the ores are produced in a separate state, the volatile part being dissipated by calcination, and the earthy part by being converted into slag, which is easily detached from the metal. It is evident, however, that if more metals than one exist in the ores they will all be reduced by the same treatment, and therefore we may, and often do, procure an alloy more or less complicated.

The *purification* of the metals is performed by various processes of refining, which are suited to their several qualities, and advantage is taken of the different properties in each to effect this. Thus, some metals are refined by their having less affinity for oxygen than others; such as gold, silver, and copper; these, not being easily oxidised in the fire, may be exposed to a strong and continued heat, which converting the inferior metals into oxides, they rise to the surface of the melted mass, from which they may be removed by various means. An example of this is the separation of lead from silver. This operation is called testing or cupellation. Another mode of refining is, when one metal is more fusible than another, whereby a separation of the two may effected. Thus tin of the first melting often contains some iron or copper, but, being melted at a very low red heat, the tin oxides, leaving the others, which do not flow but at a higher temperature. Silver is separated from copper when it is in small proportions, by adding lead to the whole infusion. The silver unites with the lead, and is separated with it afterwards by a heat which melts it out from the copper. This process is called eliquation. The silver is separated from the lead afterwards by cupellation, which is a process adapted also to procuring gold.

Where metals in the state of oxide are to be reduced into their malleable or proper form, it is done by fusion, in contact with carbon, as was described in the case of tin ores; and they are therefore mixed with small-coal, wood, or charcoal. The oxygen leaves the metal, and forms, with the carbon, carbonic acid, which escapes. Thus litharge, which is the oxide of lead obtained by cupellation, is again brought into the state of lead: this process is called reviving. Iron, in its perfect state, is nearly infusible, and it must be largely combined with carbon to make it melt freely; on which account we see the use of smelting the ores in contact with coke. The carbon is separated when it is converted into bar-iron; and, in converting this into steel, carbon is again made to combine in another proportion. Copper requires, after it is freed as much as possible from the other metals, a peculiar treatment with charcoal, and a continued melting heat; which process is called toughening. The melted metal is much stirred with wood poles, and after a time assumes the required properties of extending under the hammer without being subject to crack. The theory of this process is rather obscure. The volatile metals would of course be dissipated if they were exposed to the heat requisite for melting them out from the substances with which they are mixed in their ores in open furnaces; they are therefore distilled in retorts, which are generally made of iron. Distillation is employed in this country for obtaining zinc, and abroad also for this metal and in the mines of mercury.

The mode of extracting the precious metals most in use in Hungary and other parts of Ger-

many, as well as in all the American mines, is that of amalgamation of the ores with mercury. By this process the gold or silver is dissolved by the mercury and separated from the earthy mixture, and also from baser metals, which do not so readily combine with mercury. This process requires, however, that the ores should be previously calcined to decompose the sulphurets, and an addition of common salt is added to facilitate this decomposition; the whole is then finely powdered and triturated in water with the mercury by machines. Subsequent distillation separates and preserves the mercury, and the gold or silver is refined in the usual way.

The metals raised in this country form an important part of our national wealth: they are exported in considerable quantities in their unmanufactured state; but a greater proportion are worked up into innumerable forms, and thus contribute much more largely to the general stock, in the employment and encouragement of industry and ingenuity. The most important metals produced in Great Britain are, iron, copper, lead, tin. With respect to the first, the iron-works of this country, as is well known, are of immense extent, and are rapidly increasing in produce. By improved methods of manufacture iron has, of late years, been much reduced in price, and this has increased the demand both at home and abroad. The manufacture of iron may be computed at

Wales	150,000	tons.
Shropshire and Staffordshire	180,000	
Yorkshire and Derbyshire	50,000	
Scotland and other places	20,000	
	400,000	
	£5	per ton.
	£2,000,000	

The quantity of copper raised is about 10,000 tons; of which about 8000 tons are produced in Cornwall, and the remainder in Anglesey, Devon, Ireland, and Staffordshire. In the year 1800 the quantity of copper raised in the Cornish mines was between 5000 and 6000 tons; so that there has been an increase since that time of from 2000 to 3000 tons. The value of the whole quantity of copper in its unmanufactured state is about £1,000,000.

The lead of Great Britain probably amounts to from 30,000 to 32,000 tons. The northern parts of the kingdom, Cumberland, Durham, and Northumberland, produce 12,000 tons.

North Wales and Shropshire	8,000
Yorkshire	4,500
Derbyshire	4,000
Scotland, Devon, Cornwall, and South Wales . . .	3,000
	31,500

The value of the lead is altogether about £750,000.

Tin, as before stated, is only found in Cornwall and Devon, and the quantity has fluctuated from 2800 to 5000 tons in the year: of late we may reckon it at somewhat above 3000 tons, and its value about £400,000. We have also certain quantities of zinc, manganese, silver, antimony, and cobalt; but of these it is difficult to estimate the quantity or value.

The aggregate value of the metals of the kingdom is thus more than £4,000,000, but is increased enormously when manufactured; and they are the foundation of important branches of our commerce in our unrivalled fabrication of hardware.

Iron is exported to almost all parts of the world in its raw, as well as in its manufactured states, and in an infinite diversity of useful and ornamental forms which it would be tedious to attempt to describe.

Copper is employed largely in its simple state, particularly rolled into sheet; and is also very much used in mixture with other metals, it being the principal constituent in brass, gun-metal, and pot-metal. The town of Birmingham alone is said to require 2000 tons a year for its varied manufactures. About 3000 tons have of late been annually sent to the East Indies and America, United States; the West Indies and different countries in Europe take from us considerable supplies.

Of the large portion of lead which our mines produce a considerable part is worked up into forms which at once destroy it, so that it does not return again for use. Thus 5000 tons a year are made into small shot, partly for home consumption and partly for exportation. The quantity made into white and red-lead and principally used as pigments, and part converted into the glazing of pottery, or an ingredient of glass-making, is little, if at all, short of 10,000 tons.

Tin is an article of export to most countries; a great deal is often sent to China; and, in the manufacture of tin plate, or thin rolled iron coated with tin in the manner before described, is a large article of commerce.

Swedenborgius has very industriously and exactly described the different processes used in most parts of Europe, for the smelting of ores of iron, for the forging of that metal, and for the conversion of it into steel; but we do not find that he, or any other author, have, by experiments and discoveries, contributed much to the illustration or to the improvement of this part of metallurgy; unless, perhaps, we except those of M. Reaumur, concerning the softening of cast-iron by cementation with earthy substances. The ores of iron are known to vary much in their appearance, in their contents, in their degrees of fusibility, in the methods necessary for the extraction of their contained metal, and in the qualities of the metal when extracted.

Most ores require to be roasted previously to their fusion; some more slightly, and others with a more violent and long-continued fire. Those which contain much sulphur, arsenic, or vitriolic acid, require a long-continued and repeated roasting, that the volatile matters may be expelled. Of this kind is the black iron ore, from which the Swedish iron is said to be obtained. Some ores require a very slight roasting only, that they may be dried and rendered friable. Such are the ores called bog ores, and others which being in a calcined state, and containing little sulphureous matter, would, by a farther

calcination, be rendered less capable of being reduced to a metallic state.

The roasting of ores of iron is performed by kindling piles, consisting of strata of fuel and of ore placed alternately upon one another, or in furnaces similar to those commonly employed for the calcination of lime-stone. Some authors advise the addition of a calcareous earth to sulphureous ores during the roasting, that the sulphur may be absorbed by this earth when converted into quicklime. But we may observe, that the quicklime cannot absorb the sulphur or sulphureous acid, till these be first extricated from the ore, and does therefore only prevent the dissipation of these volatile matters; and, secondly, that the sulphur thus united with the quicklime forms a hepar of sulphur, which will unite with and dissolve the ore during its fusion, and prevent the precipitation of the metal.

The next operation is the fusion or smelting of the ore. This is generally performed in furnaces, or towers, from twenty to thirty feet high; in the bottom of which is a basin for the reception of the fluid metal. When the furnace is sufficiently heated, which must be done at first very gradually, to prevent the cracking of the walls; a quantity of the ore is to be thrown in from time to time, at the top of the furnace, along with a certain quantity of fuel and limestone, or whatever other flux is employed. When the fuel below is consumed by the fire, excited by the wind of the bellows, the ore, together with its proportional quantity of fuel and of flux, sink gradually down, till they are exposed to the greatest heat in the furnace. There the ore and the flux are fused, the metallic particles are revived by the fuel, are precipitated by means of their weight through the scoria formed of the lighter earthy parts of the flux and of the ore, and unite in the basin at the bottom of the furnace, forming a mass of fluid metal covered by a glassy scoria. When a sufficient quantity of this fluid metal is collected, which is generally twice or thrice in twenty-four hours, an aperture is made, through which the metal flows into a channel or groove made in a bed of sand; and from thence into smaller, lateral, or connected channels, or other moulds. There it is cooled, becomes solid, and retains the forms of the channels or moulds into which it flows. The piece of iron formed in the large channel is called a sow, and those formed in the smaller channels are called pigs. Sometimes the fluid iron is taken out of the furnace by means of ladles, and poured into moulds ready prepared, of sand or of clay, and is thus formed into the various utensils and instruments for which cast iron is a proper material.

The scoria must be, from time to time, allowed to flow out, when a considerable quantity is formed, through an aperture made in the front of the furnace for that purpose. A sufficient quantity of it must, however, be always left to cover the surface of the melted iron, else the ore which would fall upon it, before the separation of its metallic from its unmetallic parts, would lessen the fluidity and injure the purity of the melted metal. This scoria ought to have a certain degree of fluidity; for, if it be too thick, the revived metallic particles will not be able to overcome its tenacity, and collect together into drops, nor be precipitated. Accordingly, a scoria, not sufficiently fluid, is always found to contain much of the metal. If the scoria be too thin, the metallic particles of the ore will be precipitated before they are sufficiently metallised, and separated from the earthy and unmetallic parts. A due degree of fluidity is given to the scoria by applying a proper heat and by adding fluxes suited to the ore.

Various substances are added to assist the fusion of iron ores which are difficultly fusible. These are, 1. Ores of a fusible quality, or which, being mixed with others of a different quality, become fusible: accordingly, in the great works for smelting ores of iron, two or more different kinds of ore are commonly mixed, to facilitate the fusion, and also to ameliorate the quality of the iron. Thus an ore yielding an iron which is brittle when hot, which quality is called red-short, and another ore which produces iron brittle when cold, or cold-short, are often mixed together; not, as sometimes supposed, that these qualities are mutually destructive of each other, but that each of them is diminished in the mixed mass of iron, as much as this mass is larger than the part of the mass originally possessed of that quality. Thus, if from two such ores the mass of iron obtained consists of equal parts of cold-short and of red-short iron, it will have both these qualities, but will only be half as cold-short as iron obtained solely from one of these ores, and half as red-short as iron obtained only from the other ore. 2. Earths and stones are also generally added to facilitate the fusion of iron ores. These are such as are fusible, or become fusible when mixed with the ore, or with the earth adhering to it. Authors direct that, if this earth be of an argillaceous nature, limestone or some calcareous earth should be added; and that, if the adherent earth be calcareous, an argillaceous or siliceous earth should be added; because these two earths, though singly infusible, yet, when mixed, mutually promote the fusion of each other; but as limestone is almost always added in the smelting of iron ores, and as in some of these, at least, no argillaceous earth appears to be contained, we are inclined to believe, that it generally facilitates the fusion, not merely by uniting with those earths, but uniting with that part of the ore which is most perfectly calcined, and least disposed to metallisation; since we know that by mixing a calciform or roasted ore of iron with calcareous earth, without any inflammable matter, these two substances may be totally vitrified. Calcareous earth does indeed so powerfully facilitate the fusion of iron ores, that it deserves to be considered whether workmen do not generally use too great a quantity of it in order to hasten the operation. For, when the scoria is rendered too thin, much earthy or unmetallised matter is precipitated, and the cast iron produced is of too vitreous a quality, and not sufficiently approximated to its true metallic state.

Some authors pretend that a principal use of the addition of limestone in the smelting of iron ores is to absorb the sulphur, or vitriolic acid, of these ores: but, as we have already observed, a hepar of sulphur is formed by that mixture of

calcareous earth and sulphur, which is capable of dissolving iron in a metallic state; and thus the quantity of metal obtained from an ore not sufficiently divested of its sulphur, or vitriolic acid (which, by uniting with the fuel, is formed into a sulphur during the smelting), must be considerably diminished, though rendered purer, by the addition of calcareous earth: hence the utility appears of previously expelling the sulphur and vitriolic acid from the ore by a sufficient roasting. 3. The scoria of former smeltings is frequently added to assist the fusion of the ore; and, when the scoria contains much iron, as sometimes happens in ill-conducted operations, it also increases the quantity of metal obtained.

The quantity of these fusible matters to be added varies according to the nature of the ore; but ought in general to be such, that the scoria shall have its requisite degree of thinness, as above mentioned.

The *fuel* used in most parts of Europe for the smelting of ores of iron is charcoal. In several works, in England and Wales, iron ore is smelted by means of pit-coal previously reduced to cinders, or cokes, by a kind of calcination similar to the operation for converting wood into charcoal, by which the aqueous and sulphureous parts of the coal are expelled, while only the more fixed bituminous parts are left behind. The quality of the iron depends considerably upon the quality and also upon the quantity of the fuel employed. Charcoal is fitter than cokes for producing an iron capable of being rendered malleable by forging. The quantity of fuel, or the intensity of the heat, must be suited to the greater or less fusibility of the ore. Sulphureous, and other ores easily fusible, require less fuel than ores distinctly fusible. In general, if the quantity of fuel be too small, and the heat not sufficiently intense, all the iron will not be reduced, and much of it will remain in the scoria, which will not be sufficiently thin. This defect of fuel may be known by the blackness and compactness of the scoria; by the qualities of the iron obtained, which, in this case, is hard, white, light, intermixed with scoria, smooth in its texture, without scales or grains, rough and convex in its surface, and liable to great loss of weight by being forged; and, lastly, it may be known by observing the color and appearance of the drops of metal falling down from the smelted ore, and of the scoria upon the surface of the fluid metal, both of which are darker colored than when more fuel is used. When the quantity of fuel is sufficiently large, and the heat is intense enough, the iron is darker colored, denser, more tenacious, contains less scoria, and is therefore less fusible, and loses less of its weight by being forged. Its surface is also smoother and somewhat concave; and its texture is generally granulated. The scoria, in this case, is of a lighter color and less dense. The drops falling down from the smelted ore, and the liquid scoria, in the furnace, appear hotter and of a brighter color. When the quantity of fuel is too great, and the heat too intense, the iron will appear to have a still darker color, and more conspicuous grains or plates, and the scoria will be lighter, whiter, and more spongy. The drops falling from this melted ore, and the fluid scoria, will appear to a person looking into the furnace through the blast-hole to be very white and shining hot. The quantity of charcoal necessary to produce 5 cwt. of iron, when the ore is rich, the furnace well-contrived, and the operation skilfully conducted, is computed to be about forty cubic feet; but is much more in contrary circumstances.

The time during which the fluid metal ought to be kept in fusion before it is allowed to flow out of the furnace must also be attended to. How long that time is, and whether it ought not to vary according to the qualities of ores and other circumstances, we cannot determine. In some works the metal is allowed to flow out of the furnace every six or eight, and in others only every ten or twelve hours. Some workmen imagine that a considerable time is necessary for the concoction of the metal. This is certain, that the iron undergoes some change by being kept in a fluid state; and that, if its fusion be prolonged much beyond the usual time, it is rendered less fluid, and also its cohesion, when it becomes cold, is thereby greatly diminished. The marquis de Courtivron says that the cohesion may be restored to iron in this state by adding to it some vitrifiable earth, which he considers as one of the constituent parts of iron, and which he thinks is destroyed by the fusion too long continued. That the fusibility of cast iron does depend on an admixture of some vitrifiable earth appears probable from the great quantity of scoria forced out of iron during its conversion into malleable or forged iron, and from the loss of fusibility which it suffers nearly in proportion to its loss of scoria. The quantity of iron daily obtained, from such a furnace as is above described, is from two to five tons in twenty-four hours, according to the richness and fusibility of the ore, to the construction of the furnace, to the adjustment of the due quantity of flux and of steel, and to the skill employed in conducting the operation.

The quality of the iron is judged of by observing the appearances during its flowing from the furnace, and when it is fixed and cold. If the fluid iron, while it flows, emits many and large sparkles; if many brown spots appear on it while it is yet red hot; if, when it is fixed and cold, its corners and edges are thick and rough, and its surface is spotted, it is known to have a red-short quality. If, in flowing, the iron seems covered with a thin glassy crust, and if, when cold, its texture is whitish, it is believed to be cold-short. M. Reaumur says that dark-colored cast iron is more impure than that which is white. No certain rules for judging of the quality of iron before it is forged can be given. From brittle cast-iron sometimes ductile forged iron is produced. Cast-iron with brilliant plates and points, when forged, becomes sometimes red-short and sometimes cold-short. Large shining plates, large cavities called eyes, want of sufficient density, are almost certain marks of bad iron; but whether it will be cold or red-short cannot be affirmed till it be forged. Whiteness of color, brittleness, closeness of texture, and hardness, are given to almost any cast-iron by sudden cooling; and we may observe that, in

general, the whiter the metal is, the harder it is also, whether these properties proceed from the quality of the iron or from sudden cooling; and that, therefore, the darker-colored iron is fitter for being cast into moulds, because it is capable in some measure of being filed and polished, especially after it has been exposed during several hours to a red-heat in a reverberatory furnace, and very gradually cooled. This operation, called by the workmen annealing, changes the texture of the metal, renders it softer and more capable of being filed than before, and also considerably less brittle. M. Reaumur found that, by cementing cast-iron with absorbent earths in a red heat, the metal may be rendered softer, tougher, and consequently a fit material for many utensils formerly made of forged iron.

In Navarre, and in some of the southern parts of France, iron ore is smelted in furnaces much smaller, and of a very different construction from those above described. A furnace of this kind consists of a wide-mouth copper cauldron, the inner surface of which is lined with masonry a foot thick. The mouth of this cauldron is nearly of an oval or elliptic form. The space or cavity contained by the masonry is the furnace in which the ore is smelted. The depth of this cavity is equal to two feet and a half: the larger diameter of the oval mouth of the cavity is about eight feet, and its smaller diameter is about six feet; the space of the furnace is gradually contracted towards the bottom, the greatest diameter of which does not exceed six feet: eighteen inches above the bottom is a cylindrical channel in one of the longer sides of the cauldron and masonry, through which the nozzle of the bellows passes. This channel, and also the bellows pipe, are so inclined that the wind is directed towards the lowest point of the opposite side of the furnace. Another cylindrical channel is in one of the shorter sides of the furnace, at the height of a few inches from the bottom, which is generally kept closed, and is opened occasionally to give passage to the scoria: and above this is a third channel, in the same side of the furnace, through which an iron instrument is occasionally introduced to stir the fluid metal, and to assist, as is said, the separation of the scoria from it. The greatest height of this channel is at its external aperture on the outside of the furnace, and its smaller height is at its internal aperture; so that the instrument may be directed towards the bottom of the furnace; but the second channel below it has a contrary inclination, that, when an opening is made, the scoria may flow out of the furnace into a basin placed for its reception. When the furnace is heated sufficiently the workmen begin to throw into it alternate changes of charcoal and ore previously roasted. They take care to throw the charcoal chiefly on that side at which the wind enters, and the ore at the opposite side. At the end of about four hours a mass of iron is collected at the bottom of the furnace, which is generally about 6 cwt.; the bellows are then stopped; and when the mass of iron is become solid the workmen raise it from the bottom of the furnace, and place it, while yet soft, under a large hammer, where it is forged. The iron produced in these furnaces is of the best quality; the quantity is also very considerable, in proportion to the quantity of ore, and to the quantity of fuel employed. In these furnaces no limestone or other substance is used to facilitate the fusion of the ore.

The iron thus produced by smelting ores is very far from being a pure metal; and though its fusibility renders it very useful for the formation of cannon, pots, and a great variety of utensils, yet it wants the strength, toughness, and malleability which it is capable of receiving by further operations.

Cast-iron seems to contain a large quantity of vitreous or earthy matter mixed with the pure iron; which matter is probably the chief cause of its fusibility, brittleness, hardness, and other properties by which it differs from forged iron. The sulphur, arsenic, and other impurities of the ore, which are sometimes contained in cast-iron, are probably only accidental, and may be the causes of the red-short quality, and of other properties of certain kinds of iron: but the earthy matter above mentioned seems principally to distinguish cast-iron from forged or malleable iron; for first, by depriving the former of this earthy matter, it is rendered malleable; and secondly, by fusing malleable iron with earthy and vitrifiable matters, it loses its malleability, and is restored to the state and properties of cast-iron.

The earthy vitreous matter contained in cast-iron consists probably of some of the ferruginous earth or calx of the ore not sufficiently metallised, and also of some unmetallic earth. Perhaps it is only a part of the scoria which adheres to, and is precipitated with, the metallic particles from which it is more and more separated, as the heat applied is more intense, and as the fusion is longer continued. To separate these impurities from cast-iron, and to unite the metallic parts more closely and compactly, and thus to give it the ductility and tenacity which render this metal more useful than any other, are the effects produced by the following operations:—The first of these operations is a fusion of the iron, by which much of its impurities is separated in form of scoria; and by the second operation a further and more complete separation of these impurities, and also a closer compaction of the metallic particles, are effected by the application of mechanical force or pressure by means of large hammers. Some differences in the construction of the forge or furnace, in which the fusion or refining of cast-iron is performed, in the method of conducting the operation, and in other circumstances, are observed to occur in different places.

The following new method of shingling and manufacturing iron must not be passed unnoticed. The ore, being fused in a reverberatory furnace, is conveyed, whilst fluid, into an air-furnace, where it is exposed to a strong heat till a bluish flame is observed on the surface; it is then agitated on the surface till it loses its fusibility, and is collected into lumps called loops. These loops are then put into another air-furnace, brought to a white or welding heat, and then shingled into half-blooms or slabes. They are again exposed to the air-furnace, and the half-blooms taken out and forged into anconies,

bars, half-flats, and rods for wire; while the slabes are passed, when of a welding heat, through the grooved rollers. In this way of proceeding it matters not whether the iron is prepared from cold or red-short metal, nor is there any occasion for the use of finery, charcoal, coke, chafery, or hollow fire, or any blast by bellows, or otherwise; or the use of fluxes in any part of the process.

In one bar frequently two or more different kinds of iron may be observed, which run along its whole length; and scarcely a bar is ever found of entirely pure and homogeneous iron. This difference probably proceeds from the practice we have mentioned of mixing different kinds of ores together in the smelting; and also from the practice of mixing two or more pigs of cast-iron of different qualities in the finery of these, by which means the red-short and cold-short qualities of the different kinds are not, as we have already remarked, mutually counteracted or destroyed by each other, but each of these qualities is diminished in the mixed mass of iron, as much as this mass is larger than the part of the mass originally possessed of that quality; that is, if equal parts of red-short and of cold-short iron be mixed together, the mixed mass will be only half as red-short as the former part, and half as cold-short as the latter. For these different kinds of iron seem as if they were only capable of being interwoven and diffused through each other, but not of being intimately united or combined.

The quality of forged iron may be known by the texture which appears on breaking a bar. The best and toughest iron is that which has the most fibrous texture, and is of a clear grayish color. This fibrous appearance is given by the resistance which the particles of the iron make to their rupture. The next best iron is that whose texture consists of clear, whitish, small grains, intermixed with fibres. These two kinds are malleable both when hot and when cold, and have great tenacity. Cold-short iron is known by a texture consisting of large, shining plates, without fibres; and red-short iron is distinguished by its dark dull color, and by the transverse cracks and fissures on the surface and edges of the bars. The quality of iron may be much improved by violent compression, as by forging and rolling; especially when it is not long exposed to too violent heat, which is known to injure, and at length to destroy, its metallic properties.

A foundry of iron is, when calculated to do business on a large scale, situated near and connected with the ore and the blast furnaces, as here it is that the ore-smelting is done; and, where that is performed, castings can be executed better, and much cheaper, than when it is done at separate establishments; it is also better done, because, as more metal is heated at a time at such furnaces, there is a better chance of getting the castings perfect. It is cheaper from this very obvious circumstance, that, as the new metal is smelted, it is at once cast into the work required, instead of being run into pigs, as they are termed, to be re-heated in another furnace, and then to be founded. This additional heating, with the cost of removal and labor, is saved by founding it into what is required at its first being smelted.
